Previous: September 1961 (1 atm) Current: Septmeber 1983 (1 bar)

Beryllium (Be) Be_1(ref)

$S°(298.15\ K) = 9.44 \pm 0.15\ J\ K^{-1}\ mol^{-1}$
$\Delta_{trs}H° = 1527 \pm 25\ K$
$T_{fus} = 1560 \pm 5\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K)\ 0\ kJ\ mol$
$\Delta_{trs}H° = 6.849 \pm 0.5\ kJ\ mol^{-1}$
$\Delta_{fus}H° = 7.895 \pm 0.5\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted thermal functions for Be(α,β,cr) are derived from the studies of Ahlers (1.4-30 K, 1), Hill and Smith (4-300 K, 2), Ginnings et al. (367-1169 K, 3), and Kantor et al. (600-3200 K, 4). The mathematical and graphical treatment of these four studies yields a continuous and smooth heat capacity curve for α-Be(cr).

There are no heat capacity or enthalpy measurements for β-Be(cr). We assume a constant value of Cp = 30.0 J K^{-1} mol^{-1} for the β-region.

The entropy at 298.15 K is 0.06 J K^{-1} mol^{-1} less than that recommended by CODATA (5). This is undoubtedly due to the manner in whcih the data of Ahlers (1) and Hill and Smith (2) were merged. A detailed discussion of the heat capacities of all alkaline earth metals is in preparation.

Phase and Fusion Data

Cannon (6) has summarized the data on the polymorphic phase changes and the variation of the melting temperature of beryllium with pressure. His critical evaluation results in the recommendation that at ambient pressure there are two stable phases. His recommendations are entirely attributable to the resistance studies of Francois and Contre (7). The phases are denoted alpha(hcp) and beta(bcc).

The melting point of beryllium is fairly well defined. We adopt T_{fus} = 1560 ± 5 K based on the studies of Kantor et al. (4), Martin and Moore (8), Teitel and Cohen (9), and Loasby and Dearden (10).

The alpha-beta transition is ill-defined. There are many conflicting studies as to the value of the transition temperature and the value and sign of the derivative (dT/dP) for this transition. We adopt T_{trs} = 1527 ± 25 K based on the study of Ammonenko, et al. (11).

The enthalpies of transition and fusion are also poorly defined. Kantor, et al. (4) has measured the enthalpy of the crystal and liquid. *No data points were obtained in the beta phase region. As a result, we can only derive a combined value* for the enthalpy of transition and fusion. Following the suggestion of Abey (12), the enthalpy values of Loasby and Dearden (10) and Abey (12) have the same value for the ratio of the transition enthalpy to fusion enthalpy, even though the actual values for each enthalpy are quite different. Thus, using this ratio and the sum of the enthalpies, as determined by Kantor et al. (4), we calculate the individual enthalpies of transition and fusion. A much more detailed discussion is in progress.

Sublimation Data

See the ideal gas table for details.

Previous: September 1961 Current: September 1983

$S°(298.15\ K) = [19.539]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1560 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [15.508]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 7.895 \pm 0.05\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of liquid beryllium is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in *enthalpy, H°(1560 K) - H°(298.15 K), between the crystal and liquid.*

Heat Capacity and Entropy

The heat capacity of the liquid is derived from the measured enthalpy data of Kantor et al. (1), 17 data points in the liquid region, 1560 to 2200 K. The data was presented graphically. We adopt the reported equation: $Cp° = 6.079 + 5.138 \times 10^{-4}\ T\ cal\ K^{-1}\ mol^{-1}$. This equation is used to calculate extrapolated values from 2200 K to 3500 K and from 1150 K to 1560 K.

A glass transition temperature is assumed at 1150 K, below which the heat capacity values of crystalline beryllium are adopted. The entropy at 298.15 K is calculated in a mannner analogous to that used for the enthalpy of formation.

Transition and Fusion Data

See the crystal table for details.

Vaporization Data

There is only one reported vaporization study for Be(ℓ): Baur and Brunner (926 -1283 K, 2). This study was not considered in the analysis as it had an incorrect temperature dependence, as was also noted by Hultgren et al. (3).

The boiling point (f = 1 bar), T_{vap} = 2741.437 K, is calculated as the temperature for which $\Delta_r G° = 0$ for Be(ℓ) = Be(g). The difference in the enthalpy of formation ofa Be(ℓ) and Be(g) at T_{vap} is the enthalpy of vaporization, $\Delta_{vap}H° = 291.572\ kJ\ mol^{-1}$.

Enthalpy of Formation

The enthalpy of formation is derived from the sublimation studies of Holden et al. (1172-1552 K, 1), Gulbranson and Andrew (1103-1229 K, 2), and Hildenbrand and Murad (1400-1500 K, 4). The adopted value, $\Delta_f H°(Be, g, 298.15\ K)$ = 324 ± 5 kJ mol^{-1}, is that recommended by CODATA (5). There are additional vapor pressure studies (~20), but they have been omitted in this analysis.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6, 7), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (8) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the three levels at ~22000 cm^{-1}; the next excited state is approximately 42565 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (8).

The thermal functions at 298.15 K agree with the CODATA recommendations (5) except that the entropy differs by 0.1094 J K^{-1} mol^{-1}, since this table uses a standard state pressure of 1 bar (*CODATA recommendations are based on 1 atm*).

BERYLLIUM, ION (Be^+) IDEAL GAS M_r = 9.01163

$IP(Be^+, g) = 146882.86 \pm 0.1\ cm^{-1}$
$S°(298.15\ K) = 142.037 \pm 0.02\ JK^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1208.23 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [1219.232]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	$\epsilon_i\ cm^{-1}$	g_i
$^2S_{1/2}$	0	2
$^2P_{1/2}$	31928.8	2
$^2P_{3/2}$	31935.4	4

Enthalpy of Formation

$\Delta_f H°(Be^+, g, 0\ K)$ is calculated from $\Delta_f H°(Be, g, 0\ K)$ (1) using the spectroscopic value of IP(Be) = 75192.07 ± 0.1 cm^{-1} (899.497 ± 0.001 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rossenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Be^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Be, g, 0\ K)$ by using IP(Be) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Be(g), $Be^+(g)$, and $e^-(g)$. $\Delta_r H°(Be \rightarrow Be^+ e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first two excited states; the next excited state is 88231.2 cm^{-1} above the ground state and the first two excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

Enthalpy of Formation

No thermochemical measurement of the enthalpy of formation has been made. The selected value, $\Delta_f H°(BeBr, g, 0\ K) = 30.0 \pm 10.0$ kcal mol^{-1}, is obtained from an analysis of spectroscopic data. The adopted values for the ground state vibrational constants give $D_0{}^0 = 3.64_1$ eV by a linear Birge-Sponer extrapolation (1). Based on the ionicity correction developed by Hildenbrand (2), this value adjusts to $D_0{}^0 = 3.27_2$ eV (75.46 kcal mol^{-1}) which is adopted. $\Delta_f H°(298.15\ K)$ corresponds to 28.7 kcal mol^{-1}.

Ionic model calculations (4, 6) and bond energy correlations (5) have led to $D_0{}^0$ values of (in eV) 1.2 (4), 4.1 (5), and 2.1 (6). The latter value which is based on a Rittner potential (7) is believed to represent a minimum value for $D_0{}^0$. Additional support for the adopted value of $\Delta_f H°$ is provided by a comparison of values for the ratio $D_0{}^0$ (MX, 298.15 K)/$\Delta_{at}H°(MX_2$, 298.15 K) for the alkaline-earth halides (3). We find $D_0{}^0$(BeBr, 298.15 K)/$\Delta_{at}H°(BeBr_2$, 298.15 K) = 0.41 which is quite consistent with values of this ratio for other alkaline-earth halides.

Heat Capacity and Entropy

We estimate r_e to be 0.08 Å less than that for $BeBr_2$ (3). This estimation is made based on the observation that the ratio $r_e(MX)/r_e(MX_2)$ is near 0.96 for several alkaline-earth halides (3). The value of B_e is calculated from r_e. The value of α_e is obtained from the other constants by assuming a Morse potential function.

The ground state vibrational constants are taken from the results of a recent vibrational analysis of the $A^2\Pi$-$X^2\Sigma$ system by Reddy et al. (8). Other values (9) for these constants are slightly different than ours, but we consider them to be less accurate. It should also be noted that the values for $\omega_e x_e$ tabulated by Rosen (9) for the ground and first excited states have been inadvertently reversed. The electronic level for the $A_1{}^2\Pi_{1/2}$ state is also taken from Reddy et al. (8). The doublet splitting of this state is assumed to be 197 cm^{-1} as was observed in the emission spectrum of BeBr by Reddy and Rao (10, 11). We also include a $B^2\Sigma$ level at 27000 cm^{-1} and a $C^2\Pi$ level at 40000 cm^{-1}. These levels are estimated by analogy with those for CaBr, SrBr, and BaBr (3).

PREVIOUS: June 1975 (1 atm) CURRENT: June 1975 (1 bar)

$S°(298.15\ K) = [100.4 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 781 \pm 15\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-355.6 \pm 12.6]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [9.83 \pm 8.4]\ kJ\ mol^{-1}$

Enthalpy of Formation

A direct measurement of the enthalpy of formation has not been made. An estimate of $\Delta_f H°$ is obtained by a method suggested by Parker (1). Biltz and Messerknecht (2) have measured the enthalpies of solution of $BeCl_2$(cr) and $BeBr_2$(cr) in aqueous HCl (18.69%). Samples (3) of the dihalides were prepared from reactions of BeO-C mixtures with the halogens at elevated temperatures. We assume that the two dihalides had similar structures, i.e. α form. $\Delta_f H°(BeBr_2$, in 18.7% HCl, 298.15 K) is estimated as -140.1 kcal mol^{-1} by combining $\Delta_{sol} H°$ of $BeCl_2$(cr) with $\Delta_f H°(\alpha\text{-}BeCl_2$, cr, 298.15 K) = -117.3±0.8 kcal mol^{-1} (4) and twice the difference in $\Delta_f H°(HCl \cdot 8.8H_2O$, 298.15 K) and $\Delta_f H°(HBr \cdot 8.8H_2O$, 298.15 K) which is -21.2 kcal mol^{-1} (5). The heat associated with the interchange of the aqueous anions is assumed to be negligible. Combination of the estimated value for $\Delta_f H°(BeBr_2$, in 18.7% HCl, 298.15 K) with $\Delta_{sol} H°$ = -55.7 kcal mol^{-1} (2) gives $\Delta_f H°(BeBr_2$, cr, 298.15 K) = -84.4 kcal mol^{-1} which is essentially the value adopted by NBS (6). Subsequent measurements by Biltz et al. (7) in less concentrated HCl(1.48%) solutions lead to $\Delta_f H°(298.15\ K)$ equal to -85.6 kcal mol^{-1} by a similar route. We adopt an average value of -85.0 kcal mol^{-1} (-355.64 kJ mol^{-1}) but emphasize that the uncertainty in $\Delta_f H°$ is much greater than that indicated (~1.0 kcal mol^{-1}) by the agreement of these two results. A combined total uncertainty of ±3.0 kcal mol^{-1} (±12.552 kJ mol^{-1}) is believed to be more realistic.

Heat Capacity and Entropy

No low-temperature heat capacity or high-temperature enthalpy measurements have been reported. We estimate $C_p°(298.15\ K)$ = 15.78 cal $K^{-1}\ mol^{-1}$ from the reaction BeF_2(cr) + 2LiBr(cr) = $BeBr_2$(cr) + 2LiF(cr) by assuming $\Delta C_p° = 0$. Comparison of this value with $C_p°$ data for α,β-$BeCl_2$ (4) suggests that our estimate is reasonable. $C_p°$ data above 298 K are estimated graphically by comparison with those for α,β-$BeCl_2$ and $MgCl_2$(4).

Several methods of estimation predict that the value of S°(298.15 K) should lie near 24.0 cal $K^{-1}\ mol^{-1}$. Application of the Berthelot principle (8) to the process $SrBr_2$(cr) + Be(cr) = Sr(cr) + $BeBr_2$(cr) and additive entropy constants (9) give values of 24.1 and 24.0 cal $K^{-1}\ mol^{-1}$, respectively. A graphical comparison of the standard entropies for other alkaline-earth dihalides (4) suggests values for S°(298.15 K) in the range 23.5-24.5 cal $K^{-1}\ mol^{-1}$. Literature estimates have included (in cal $K^{-1}\ mol^{-1}$) 29 (10) and 22 (11). We adopt S°(298.15 K) = 24.0±1.0 cal $K^{-1}\ mol^{-1}$ (100.416±4.184 J $K^{-1}\ mol^{-1}$).

Fusion Data

The reported melting points for $BeBr_2$ show an unusual amount of scatter. Values of T_{fus} include 761 K (12), 763 K (13), and 779-781 K (14). Semenenko and Naumova (14) reported encountering difficulties in handling $BeBr_2$ due to its hygroscopic nature and susceptibility to oxidation by traces of oxygen. These factors could account for the discrepancies in the T_{fus} values. We tentatively adopt the highest value of 781 K (14) but believe that T_{fus} is more uncertain (~15 K) than the accuracy (±5 K) claimed in their temperature measurements.

A thermal analysis (14) of $BeBr_2$ up to temperatures near the melting point showed no polymorphic modifications. Also, the interpretation of electron-diffraction patterns for freshly sublimed $BeBr_2$ indicated that it is isostructural with the α form of $BeCl_2$. Thus, we estimate $\Delta_{fus} H°$ = 2.35±2.0 kcal mol^{-1} from $\Delta_{fus} S°$ = 3.0 cal $K^{-1}\ mol^{-1}$ which is calculated for α-$BeCl_2$ (4).

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ is obtained from an analysis of the sublimation pressures reported by Rahlfs and Fischer (12). Further details of the analysis are given on the gas-phase table. The value, T_{sub} = 752 K, is the temperature at which ΔG approaches zero for the process $BeBr_2$(cr) = $BeBr_2$(g). T_{sub} has been measured as 746 K (12). The good agreement between the calculated and observed values of T_{sub} is believed to indicate the presence of only small amounts of dimer in the saturated vapor of $BeBr_2$ near the melting point. However, this conflicts with other evidence which is discussed on the gas-phase table. Our results show that $T_{sub} < T_{fus}$ which implies that the liquid phase is thermodynamically unstable under ordinary conditions.

BERYLLIUM BROMIDE ($BeBr_2$) IDEAL GAS M_r = 168.82018

$S°(298.15\ K) = 273.9 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-215.8 \pm 16.7]\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-229.3 \pm 16.7]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[227] (1)
220 (2)
1010 (1)

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Be-Br = 1.91 ± 0.02 Å

Bond Angle: Br-Be-Br = 180°

Rotational Constant: B_o = [0.028916] cm^{-1}

Enthalpy of Formation

Rahlfs and Fischer (1) have reported measurements of the sublimation pressures (624-695 K) and vapor densities (736-799 K) for $BeBr_2$. Both measurements were complicated by significant reaction of the dibromide with the quartz apparatus. Assuming the reaction to be $2BeBr_2(cr) + SiO_2(cr) = SiBr_4(g) + 2BeO(cr)$, Rahlfs and Fischer (1) corrected their measured total pressure for the partial pressure of the tetrabromide. Results of a 2nd and 3rd law analyses of their data are tabulated below.

Measurement	No. of Points	T/K	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Sublimation Pressures[a]	8[b]	624-695	31.0	30.2±0.1	-1.0±0.8	-54.8
Vapor Densities- Total Pressures[c]	4	736-799	23.9	33.4±1.0	12.4±9.0	-51.6

[a]Pressures assigned to monomer.
[b]One point rejected due to failure of a statistical test.
[c]Pressures corrected for dimer.

The vapor density measurements (1) predict about 50% dimerization at temperatures near the melting point (T_{fus} = 781 K). This value appears to be unusually high when compared with dimerization data which are available for $BeCl_2$, $MgBr_2$, $MgCl_2$, and MgF_2 (2). Mass spectral studies of these alkaline-earth dihalides show the presence of only small amounts (1-5%) of dimer in the saturated vapors up to temperatures near their melting points. Electron-diffraction experiments on $BeBr_2$ vapor are also inconsistent with high concentrations of dimer. It is quite likely that the monomer and dimer pressures reported by Rahlfs and Fischer (1) from their vapor density measurements are unreliable. Thus, we choose to adopt $\Delta_f H°(298.15\ K) = -54.8$ kcal mol^{-1} rather than the average value (-53.2 kcal mol^{-1}) of these two results. The sublimation pressures (1) are assigned solely to the monomer pending resolution of the dimerization problem. Also, $\Delta_f H°(g)$ is placed in brackets to emphasize the uncertainties in $\Delta_f H°(cr)$.

Heat Capacity and Entropy

Information available on the structure of $BeBr_2$ tend to indicate that the molecule is linear. Electron-diffraction patterns (3, 4) for $BeBr_2$ vapor have been successfully interpreted in terms of a linear configuration. Buchler et al. (5), using electric quadrupole deflection of molecular beams to detect permanent dipole moments in molecules, have shown that for the gaseous alkaline-earth dihalides the linear form is favored by a light metal-heavy halogen combination. The matrix-isolation spectrum (6) of $BeBr_2$ shows the two infrared-active vibrations which would be expected for a linear molecule. We adopt the linear configuration. The bond length is taken from the electron-diffraction studies of Akishin (3, 4).

The asymmetric stretching (ν_3) and bending (ν_2) frequencies ahve been observed in the matrix-isolation spectrum of $BeBr_2$ by Snelson (6). The adopted frequencies are gas-phase values which were estimated by Snelson (6) from the matrix data. The infrared-inactive symmetrical stretching frequency (ν_1) is calculated from an estimated force constant by a simple valence force field approximation (7). The stretching force constant (K = 2.430 x 10^5 dynes/cm) is assumed equal to that for BeBr (2). Literature estimates of ν_1 include (in cm^{-1}) 230 (6, 8) and 209 (9). The ground state quantum weight of one is assigned by analogy with $BaCl_2$ (2).

Brewer et al. (8) have tabulated Gibbs energy functions for $BeBr_2$ up to 1500 K. Their values are consistently lower than ours by about 2.5 cal K^{-1} mol^{-1}. These differences are due entirely to the higher bending frequency (ν_2 = 446 cm^{-1}) which was used by Brewer et al. (8). This estimated value is now known to be incorrect.

Enthalpy of Formation

Novikov (1) measured 39 bands in the ultraviolet spectrum of BeCl(g). A linear extrapolation leads to a ground state dissociation energy of 36,555 cm^{-1}. The authors assumed that the non-crossing rule applied and that the ground and first excited states had a common dissociation limit. However, in the analogous case of BeF, treated in the same way by the above authors, it was shown by Mann (2) that these assumptions were not correct. If it is assumed that the excited state dissociates $A^2\pi$ + Be(^{3}P) + F(^{2}P) and the ground state $X^2\Sigma$ + Be($^1S_0$) + F(^{2}P) then ν_{oo} + D' should equal D" + Excitation energy of Be atom. We find ν_{oo} + D' = 27,960 + 30,390 = 58,350 and D" + E_{Be} = 36,555 + 21,981 = 58,536 which is excellent agreement. Thus, the dissociation energy to ground state atoms is taken as 104.5 kcal mol^{-1} which leads to a enthalpy of formation of 3 kcal mol^{-1} using reaction a.

Greenbaum et al. (3) report equilibrium constants for reaction b in the temperature range 1573-1724 K using the molecular flow effusion method. Also Hildenbrand et al. (4) report equilibrium constants for reaction c and d which were calculated from mass spectrometric ion intensities. The $\Delta_r H°(298.15\ K)$ values by 2nd and 3rd law analysis for these data and the corresponding $\Delta_f H°(298.15\ K)$ values are listed below.

Author	Method	Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Novikov	Spectroscopic	(a) BeCl(g) + Be(g) + Cl(g)		104.5			2.677
Greenbaum	Kp	(b) $BeCl_2$(g) + Be(l) + 2 BeCl(g)	1573-1724	93.56±7	85.87	-4.521	5.2 1.3
Hildenbrand	Kp from Mass	(c) Be(g) + AlCl(g) + BeCl(g) + Al(g)	1382-1554	27.5 ±2			16.5 ± 3
	Spectroscopy				26.25	- .779	15.3 ± 2
		(d) Be(g) + BeCl(g) + 2 BeCl(g)	1382-1536	33.41±8			12.8 ± 5
					36.08	2.198	14.1 ± 2.5

The equilibrium data of Greenbaum et al. (3) was not weighted, since calculations indicated the possiblility of reaction of BeCl(g) with the Al_2O_3 tube at the temperatures and pressures used. The data of Hildenbrand et al. (4) which reflect the true gas phase equilibria and appear consistent with each other were adopted yielding $\Delta_f H°(298.15\ K) = 14.5$ kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational constants used to calculate the functions were derived by Novikov (1) from a two constant equation [$\omega_o'' - (2\ \nu'' + 1)\omega_o'' x_o'' = \Delta G_o''(\nu'')$]. The electronic levels were obtained from Herzberg (5). B_e was obtained from the estimated bond length, which was taken to be slightly less than that in $BeCl_2$(g) and α_e was estimated from the Morse potential function.

$\omega_e = [700]\ cm^{-1}$ $\omega_e x_e = [4.8]\ cm^{-1}$ $\sigma = 1$
$B_e = [0.7241]\ cm^{-1}$ $\alpha_e = [0.0071]\ cm^{-1}$ $r_e = [1.8]$ Å

Enthalpy of Formation

Krasnow (1) has reported calculations of the ionization potentials (IP) for the monohalides (MX, where X = F, Cl, Br, and I) of Group IIA elements (M = Mg, Ca, Sr, and Ba). Based on his data we obtain graphically the value IP(BeCl, g) = 8.9 ± 0.5 eV. The value of $\Delta_f H°(298.15\ K)$ is derived as 219 ± 15 kcal mol^{-1}, using $\Delta_f H°(BeCl, g, 0\ K) = 13.9$ kcal mol^{-1}. Beckett (2) reported the ionization potential of BeCl(g) to be approximately 9 ± 1 eV, yielding $\Delta_f H°(298.15\ K) = 222 \pm 23$ kcal mol^{-1}. Hildenbrand (9) measured the appearance potential (AP) of $BeCl^+(g)$ to be 9.5 ± 0.7 cal $K^{-1}mol^{-1}$ which is on the same order of the above IP values, and assumed that IP($BeCl^+$, g) = AP($BeCl^+$, g) = 9.5 ± 0.7 eV. Using this IP value, we obtain $\Delta_f H°(298.15\ K) = 234 \pm 20$ kcal mol^{-1} which is adopted.

Heat Capacity and Entropy

The six electronic states are obtained from Fougere (3). The electronic levels are estimated by comparison with those of the isoelectronic molecules, BeS (4), BeO (5, 6), and MgO (5, 7). The values of ω_e, $\omega_e x_e$ are estimated by comparison with those for BeCl(g) and LiCl(g). B_e and α_e are calculated using the method suggested by Herzberg (5). The bond distance is estimated (8).

Rotational Constant: B_o = [0.12970G] cm^{-1}

Enthalpy of Formation

The enthalpy of formation was estimated by assuming $\Delta_r H° = 0$ for the reaction $BeF_2 + BeCl_2 \rightarrow 2BeClF$.

Heat Capacity and Entropy

The structure, bond lengths and frequencies were all estimated from the properties of $BeCl_2$ and BeF_2.

PREVIOUS: June 1965 (1 atm) CURRENT: June 1965 (1 bar)

BERYLLIUM CHLORIDE, ALPHA (α-$BeCl_2$) CRYSTAL M_r = 79.91818

$S°(298.15\ K) = 82.68 \pm 0.25\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 688\ K$

$\Delta_f H°(0\ K) = -491.8 \pm 3.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -490.9 \pm 3.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 8.66 \pm 0.25\ kJ\ mol^{-1}$

Enthalpy of Formation

Johnson and Gilliland (1) have directly reacted beryllium and chlorine and obtained $\Delta_f H° = -118.03 \pm 0.56$ kcal mol^{-1} though the crystal form of the product was unknown. Gross, Heyman, Greene and Bingham (2) also by direct combustion of the elements obtain $\Delta_f H° = -117.1 \pm 0.4$ kcal mol^{-1}. The crystal form of the sample was deduced to be α' by a comparison experiment, the assumption is made here that α and α' are identical. Thompson, Sinke and Stull (3) by solution calorimetry report a $\Delta_f H° = -118.25 \pm 0.5$ kcal mol^{-1}. Initially this sample was reported to be of unknown crystal form. However, Sinke (4) reports that an x-ray of the sample used has been reinterpreted, in the light of more recent data, as being approximately 50% α' and 50% β. Using the enthalpies of transition adopted for these tables, enthalpies of formation of -117.3 ± 0.8 kcal mol^{-1} for α and -118.6 ± 0.8 kcal mol^{-1} for β have been adopted as being the most consistent with all measurements.

Heat Capacity and Entropy

McDonald and Oetting (5) have measured the heat capacity of the α' form from 13 and 304 K and the enthalpy (relative to the α' form) from 676 to 688 K. The assumption has been made that the α and α' forms are identical and the heat capacity curve between 304 and 676 K has been estimated graphically. The entropy was obtained by integration of the heat capacity curve assuming $S°(13\ K) = 0.16$ cal $K^{-1}\ mol^{-1}$. The sample was identified as α' by x-ray diffraction both before and after the experiments.

Fusion Data

The temperature and enthalpy of melting were reported by McDonald and Oetting (5). Several investigations of the melting point are in disagreement mainly due to the uncertainty of the crystal form of the material and a solid state transition just below the pure α-liquid melting point.

Sublimation Data

The adopted enthalpy of sublimation was calculated from that of the β form and enthalpy of the α-β transition at 298.15 K.

$\Delta_f H°(298.15\ K) = -496.2 \pm 3.3\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [15.27 \pm 0.63]\ kJ\ mol^{-1}$
$\Delta_{trs} H° = [6.82 \pm 0.63]\ kJ\ mol^{-1}$

Enthalpy of Formation

See the α-crystal table for details.

Heat Capacity and Entropy

McDonald and Oetting (1) have measured the heat capacity of the β-form from 13 to 304 K and the enthalpy of the β-form from 298 to 676 K. The entropy was obtained by integration of the heat capacity curve based on $S°(13\ K) = 0.06\ cal\ K^{-1}\ mol^{-1}$. The sample was identified as β-$BeCl_2$ both before and after the low temperature experiments.

Fusion Data

The temperature and enthalpy of melting were obtained from cross over point of the tables for β-$BeCl_2$ and liquid $BeCl_2$.

Transition Data

The temperature of the $\beta \rightarrow \alpha$ transition was obtained from McDonald and Oetting (1). The enthalpy of the transiton is a function of the heat capacity curve chosen for α-$BeCl_2$ between 298 and 676 K. A straight line interpolation was used by McDonald and Oetting, which gives a different result (1.49 kcal mol^{-1}) than the curve employed here. It should also be noted that the transitional enthalpy is not included in this table, which is for β-$BeCl_2$ only.

Sublimation Data

The enthalpy of sublimation was determined by 2nd and 3rd law analysis of vapor pressure data as described fully on the table for $BeCl_2(g)$.

BERYLLIUM CHLORIDE ($BeCl_2$) LIQUID M_r = 79.91818

$S°(298.15\ K) = [79.727]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 688\ K$

$\Delta_f H°(298.15\ K) = [-491.313]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 8.66 \pm 0.25\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the α-$BeCl_2$ by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(688 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

McDonald and Oetting (1) have measured the enthalpy of the liquid, relative to α-$BeCl_2$, from 688 to 713 K. The heat capacity was assumed constant above this point and also below the melting point to 460 K where a glass transition was assumed. Below 416 K the heat capacity was assumed to be that of β-$BeCl_2$. *The entropy is calculated in a manner analagous* to that used for the enthalpy of formation.

Fusion

See α-crystal table for details.

Vaporization Data

The boiling point and enthalpy of vaporization are calculated from the cross over point of the $BeCl_2$ (ℓ) and (g) tables. The analysis of the liquid vapor pressure data is given on the table for $BeCl_2$(g).

Rotational Constant: B_o = 0.0759 cm^{-1} 0.075887

Enthalpy of Formation

The vapor pressure data over the crystal was assumed to be for the β-form. The 2nd and 3rd law analyses of the data are summarized below after conversion to a common process. The data were also analyzed using gaseous Gibbs energy functions based on a bending frequency of 170 cm^{-1} but no significant improvement of the results was noted.

Source	T/K	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
(1)	680-740*	33.5 ± 0.6	31.38	-3.4 ± 0.7
(2)	680-740	34.3	31.22	-4.7

(3)	441-518	31.4 ± 0.8	32.45	2.5 ± 1.7
(3)	510-600*	31.8 ± 0.3	32.07	0.40± 0.5
(4)	460-504*	32.45± 0.4	32.48	0.14± 0.8

*Points rejected due to failure of a statistical test.

It is obvious that there is no real agreement between the data sets, and some of this is undoubtedly due to the difficulty of keeping a single crystal form throughout a series of measurements. It is also doubtful that water vapor was adequately excluded in some experiments. We have adopted the only piece of work which shows adequate 2nd and 3rd law agreement, and no 3rd law trend, that is $\Delta_{sub}H°$ = 32.5 ± 1 kcal mol^{-1} from (4). It is interesting to note that all the other data can be made much more precise and its drift removed if a constant pressure is added to all points. The addition which varied from 20-30% of the lowest pressure in each data set serves to indicate the magnitude of possible systematic errors.

Heat Capacity and Entropy

The linear structure of $BeCl_2(g)$ has been confirmed by the electric deflection experiments of Buchler (5). The bond length was obtained from the electron diffraction data of Akishin, Spirodinov and Sobelev (6). Buchler and Klemperer (7) have reported the infra-red spectrum and assigned 1113 as the asymmetric stretch ν_3 and 482 as the bending frequency ν_2. However, Snelson (8) using matrix isolation experiments, has shown this second band to be due to beryllium chloride solid. The unobserved frequencies were estimated from a valence force field treatment by assuming that the ratio of stretching to bending force constant was 50:1, the same as for $BeF_2(g)$. This gives 230 cm^{-1} for ν_2 and 375 cm^{-1} for the symmetric stretch.

BERYLLIUM FLUORIDE (BeF) IDEAL GAS M_r = 28.010583

Ground State Configuration: $^2\Sigma^+$

$S°(298.15\ K) = [205.75 \pm 0.04]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -172.2 \pm 8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -169.9 \pm 8\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i	ε_i, cm^{-1}	g_i
0.0	2	50419	2
33180	4	63916	[4]
49573	2	66373	[4]

$\omega_e = 1265.9\ cm^{-1}$ $\omega_e x_e = 9.35\ cm^{-1}$ $\sigma = 1$

$B_e = 1.489\ cm^{-1}$ $\alpha_e = 0.0176\ cm^{-1}$ $r_e = 1.361$ Å

Enthalpy of Formation

$\Delta_f H°$ is based on 3rd law analysis of Kp data for three gas-phase reactions observed mass spectrometrically by Hildenbrand et al. (1, 2). Our analysis is summarized below. Also included are data for heterogeneous reaction of Be(cr, ℓ) with BeF_2(g), observed with a molecular-flow-effusion method by Greenbaum et al. (3). The mutual consistency of the gas-phase results prompts us to adopt a weighted average of -40.6 ± 2 kcal mol^{-1} *rather than the mean value of* -53.1 kcal mol^{-1} *derived from the* heterogeneous reaction.

Analogous studies of BeCl(g) gave a similar discrepancy which was reaffirmed by new transport studies of Gross and Lewin (4). These authors suggested that transport via $(BeCl)_2$ provides a possible, but inconclusive, explanation of the discrepancy. This explanation may also apply to BeF, but new data would be needed to establish this.

The adopted $\Delta_f H°$ yields D_0^0 = 5.98 ± 0.1 eV which is consistent with spectroscopic results within their probable uncertainties (5). Spectroscopic values (1, 5) include 6.3 or 6.0 ± 0.5 eV (from $A^2\Pi$) and 5.3 cal K^{-1} mol^{-1} (from $X^2\Sigma$). Rationales have been given (5-8) *for the lowness of the value derived from the ground state. Recent calculations (13) showed* that the ground-state potential energy curve is consistent with D_0^0 = 5.85 eV. The flow-effusion data (3) yield 6.52 cal K^{-1} mol^{-1}.

Source	Method	Reaction[a]	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	δS cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Hildenbrand (1)	Mass Spec.	A	1458-1609	25.9±9	28.28±2	-1.6±5.7	-41.86±1.3
		A	1321-1518	31.2±2	29.09±2	1.5±1.5	-41.46±1.3

		E	1570-1675	83. ±6	80.7 ±3	-1.2±3.7	-53.4 ±1.6

[a] A) Be(g) + BeF_2(g) → 2BeF(g); B) Be(g) + CaF(g) → BeF(g) + Ca(g);
C) Be(g) + AlF(g) → BeF(g) + Al(g); D) BeF_2(g) + Be(cr) → 2BeF(g);
E) BeF_2(g) + Be(ℓ) → 2BeF(g).

Heat Capacity and Entropy

Rotational constants are from a new analysis of the A-X system by Walker and Barrow (9). Vibrational constants are those derived by Novikov and Gurvich (10) from data of Tatevskii et. al. (11). Excited states are from Novikov and Gurvich (10). We assume that the two highest states are $^2\Pi$ as postulated by Walker and Barrow (9) from comparison with quantum calculations (12).

PREVIOUS: December 1971 (1 atm) CURRENT: December 1971 (1 bar)

$S°(298.15\ K) = 53.354 \pm 0.17\ J\ K^{-1}\ mol^{-1}$
T_{trs} = 500 K (low quartz → high quartz)
T_{fus} = 825 K

$\Delta_f H°(0\ K) = -1024.5 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1026.8 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0.2201\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 4.757\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is the value selected by Parker (1), based on a thorough review of data for BeF_2(cr, vitreous, aq) and BeO(cr). Parker's analysis remains essentially unchanged for BeO(cr) and BeF_2(cr), even though the results for BeF_2(HF, aq) become more negative by 0.93 kcal mol^{-1} due to JANAF selections for HF(aq). Three values derived by Parker for BeF_2(cr) from PbF_2(cr) are changed due to JANF auxiliary data; these values become -246.9, -246.0 and -247.2 for the three paths used by Parker.

The adopted $\Delta_f H°$ was derived by combination of calorimetric data for Be(cr) + F_2(g) → BeF_2(vitreous) and BeF_2(cr) → BeF_2 (vitreous). Churney and Armstrong (2) obtained $\Delta_f H°(298.15\ K) = -244.32 \pm 0.8$ kcal mol^{-1} for vitreous BeF_2 by combustion in fluorine of polytetrafluoroethylene and mixtures of Be(cr) with polytetrafluoroethylene. $\Delta_r H°(298.15\ K$, cr → vitreous) = 1.125 ± 0.016 kcal mol^{-1} was measured via solution calorimetry by Taylor and Gardner (3).

Heat Capacity and Entropy

Cp° is based on JANAF curve fits of measurements by adiabatic calorimetry (8-300 K) and by ice calorimetry (354-776 K) as reported by Taylor and Gardner (3). The sample was estimated as approximately 99.5% BeF_2. Analyses indicated that the major impurity was about 0.3% oxygen, mainly in the form of absorbed water. Petrographic examination and X-ray diffraction showed the sample to be composed almost completely of quartz-type crystals. The entropy is derived from the smoothed Cp° based on the extrapolation S°(8 K) = 0.0065 cal K^{-1} mol^{-1}. The adopted $C_p°$ above 300 K agrees closely with the relative enthalpy data and shows a remarkable similarity to that of SiO_2 (low quartz, high quartz).

Transition Data

T_{trs} is the value selected by Taylor and Gardner (3) from their relative enthalpy data. $\Delta_{trs} H°$ is the corresponding difference in relative enthalpy from the JANAF curve fits for the two crystalline forms. Levina (4) studied the polymorphism of BeF_2 by observing the peaks in Cp near the transition temperatures. For low quartz → high quartz, Levina's peak began near 438 K, was complete near 503 K, and gave $\Delta_{trs} H° = 0.17$ kcal mol^{-1}. Levina found a 2nd transition attributed to a form analogous to tridymite; this began above 670 K, was complete by 740 K, and gave $\Delta_{trs} H° = 0.24$ kcal mol^{-1}. There is no evidence for this transition in the relative enthalpy data, so we suspect that its occurrence may be due to impurities in Levina's sample. Levina also found that the cristobalite-like phase transformed in the region 380 to 420 K with $\Delta_{trs} H° = 1.27$ kcal mol^{-1}.

Fusion Data

See the liquid table for details.

Sublimation Data

See the ideal gas table for details.

BERYLLIUM FLUORIDE (BeF_2) LIQUID M_r = 47.008986

$S°(298.15\ K) = [59.920]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 825\ K$

$\Delta_f H°(298.15\ K) = [-1022.048]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 4.757\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of the crystal by means of $\Delta_r H° = 1.125 \pm 0.016$ kcal mol^{-1} for BeF_2(cr) + BeF_2(vitreous) at 298.15 K. Further details are given in the section on Fusion Data. $\Delta_f H°(\ell)$ actually is based on the direct determination of $\Delta_f H°$(virteous) by Churney and Armstrong (1) as discussed on the crystal table.

Heat Capacity and Entropy

Cp° is based on a JANAF curve fit of relative enthalpies of Taylor and Gardner (2) for the liquid (828-1183 K) and vitreous (320-473 K) forms of BeF_2. The combined data yeild a normal Cp° curve and reveal no need for a glass transition. Scatter in the data is somewhat larger than for the crystal, presumably due to minor variations in the vitreous state at the conclusion of each drop. S°(298.15 K, ℓ) is calculated from that of the crystal by addition of $\Delta_{fus}S°$ and the difference for crystal and liquid of S°(825 K) - S°(298.15 K).

Fusion Data

T_{fus} is the value selected by Taylor and Gardner (2) from their relative enthalpy data. These showed premelting starting near 804 K and complete melting above 828 K. Cooling of the liquid produced the vitreous state. T_{fus} has also been reported as 815 (3), 821 (4), 818 (5), and 816 ± 5 K (6).

Solution calorimetry (2) gave $\Delta_r H° = 1.125 \pm 0.016$ kcal mol^{-1} for BeF_2(low quartz) + BeF_2(vitreous) at 298.15 K. Confirmation of ths result came from transposed temperature-drop calorimetry (7) and calorimetric conversion (8). These gave 1.1 ± 0.2 and 1.1 ± 0.5 kcal mol^{-1}, respectively. Combination of $\Delta_r H° = 1.125$ with JANAF enthalpies yields $\Delta_{vap}H° = 1.137$ kcal mol^{-1}.

Vaporization Data

T_{vap} is the calculated temperature at which $\Delta_r G° = 0$ for $BeF_2(\ell)$ + $BeF_2(g)$; $\Delta_{vap}H°$ is the corresponding value of $\Delta_r H°$ at T_{vap}. These calculations neglect the presence of dimer, which is assumed to be negligible based on extrapolation of the equations of Belousov (9). Cantor (10) obtained T_{vap} = 1442 K by extrapolation of his vapor pressures (1146-1372 K).

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of the crystal by means of $\Delta_f H°(298.15\ K) = 55.15 \pm 0.1\ kcal\ mol^{-1}$. The selected value of $\Delta_{sub} H°$ is an average of those obtained by 3rd law analysis of vapor pressures measured by manometry (3), torsion effusion (4) and entrainment (8-10). Mass-spectrometric data (1, 2) are in reasonable agreement and so is the average of two Knudsen-effusion studies (6, 7). Several techniques (2, 4, 6) were used to show that the amount of dimer in the vapor is negligible up to at least 1000 K. JANAF analyses of the vaporization data are summarized as follows:

Source	Method	T/K	δS cal K^{-1} mol^{-1}	$\Delta_{sub} H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law

Heat Capacity and Entropy

The bond length and angle are those derived by Akishin et al. (11) from electron-diffraction data for the vapor. Linearity of BeF_2 was confirmed by electric-deflection studies (12) of the vapor and by infrared studies (13) of matrix-isolated BeF_2. Infrared absorptions were found near 330 and 1540 cm^{-1} in neon matrices, leading to gas-phase estimates of 345 and 1555 cm^{-1} (13). The latter absorption was observed (14) at 1520 cm^{-1} in the infrared spectra of the vapor at 1000°C. We adopt a compromise of 1530 cm^{-1} and use this value in the valence-force-field approximation to estimate 670 cm^{-1} for the symmetric stretching mode.

PREVIOUS: June 1970 (1 atm) CURRENT: June 1970 (1 bar)

LITHIUM TETRAFLUOROBERYLLATE ($LiBeF_3$) CRYSTAL M_r = 72.98389

$S°(298.15\ K) = 89.24 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

T_{fus} = [650 K]

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -1651.8 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [27.196]\ kJ\ mol^{-1}$

Enthalpy of Formation

Interpolation of the calorimetric enthalpies of mixing of Holm and Kleppa (1) yields $\Delta_r H° = -0.56 \pm 0.1$ kcal mol^{-1} for $LiF(\ell) + BeF_2(\ell) \rightarrow LiBeF_3(\ell)$ at 1135 K. Reduction with the estimated JANAF functions yields $\Delta_r H° = -3.07 \pm 1.0$ kcal mol^{-1} at 298.15 K for $LiF(cr) + BeF_2(\ell) \rightarrow LiBeF_3(cr)$, where $BeF_2(\ell)$ is the supercooled liquid. $\Delta_r H°(298.15\ K)$ for the latter reaction may also be calculated as -2.77 ± 0.2 kcal mol^{-1} from the difference of two calorimetric reactions measured by Gross (2). These results at 298.15 K were $\Delta_r H° = -2.28 \pm 0.12$ kcal mol^{-1} for $LiF(cr) + LiBeF_3(cr) \rightarrow Li_2BeF_4(cr)$ and $\Delta_r H° = -5.06 \pm 0.06$ kcal mol^{-1} for $2LiF(cr) + BeF_2(\ell) \rightarrow Li_2BeF_4(cr)$. We adopt the high-temperature results of Holm and Kleppa since the entropy must be calculated by combination of $\Delta_r H°$ with $\Delta_r G°$ obtained at high temperature.

Heat Capacity and Entropy

$C_p°$ is estimated from $C_p°$ of $Li_2BeF_4(cr)$ minus $C_p°$ of LiF(cr). Existing information leads to three values for S° at 298.15 K; namely 21.41 cal $K^{-1}\ mol^{-1}$ from $\Delta_r G°$ and $\Delta_r H°$ for mixing of molten LiF and BeF_2, 21.33 cal $K^{-1}\ mol^{-1}$ from $\Delta_r G° = 0$ at 552 K for disproportionation of $LiBeF_3(cr)$ to $Li_2BeF_4(cr)$ and $BeF_2(cr)$, and 21.28 cal $K^{-1}\ mol^{-1}$ estimated from S° of LiF(cr) and $BeF_2(cr)$. We adopt the intermediate value but emphasize that S°(298.15 K) is much more uncertain than indicated by the consistency of the three values. There is less uncertainty in S°(900 K) since it does not involve large contributions from the estimated values of $C_p°$ and $\Delta_{fus} H°$.

Hitch and Baes (3) reported emf data and activity coefficients which yield $\Delta_r G° = -5.91$ kcal mol^{-1} at 900 K for $LiF(\ell) + BeF_2(\ell) \rightarrow LiBeF_3(\ell)$. Combining $\Delta_r G°$ with $\Delta_r H° = -1.05$ kcal mol^{-1} derived with JANAF functions from data of Holm and Kleppa (1), we obtain $\Delta_r S° = 5.4$ and $S°(LiBeF_3, \ell) = 64.46$ cal $K^{-1}\ mol^{-1}$, both at 900 K. The corresponding values from the adopted tables are $\Delta_r G° = -5.84$ kcal mol^{-1} and $S°(LiBeF_3, \ell) = 64.38$ cal $K^{-1}\ mol^{-1}$.

Disproportionation Data

No transitions are known between room temperature and T_{fus}, but $LiBeF_3(cr)$ does disproportionate into $Li_2BeF_4(cr)$ and BeF_2 (high quartz). Disproportionation occurs at 553 K according to the latest phase diagrams (4, 5) or at 573 K according to Roy et al. (6). The adopted tables yield $\Delta_r G° = 0$ at 552 K, but this temperature is very sensitive to the value selected for S°, which in turn depends on the estimates of $C_p°$ and $\Delta_{fus} H°$.

Fusion Data

See the liquid table for details.

PREVIOUS: June 1966 CURRENT: December 1971

$S°(298.15\ K)$ = [111.681] J K^{-1} mol^{-1}

T_{fus} = [650] K

$\Delta_f H°(298.15\ K)$ = [-1634.323] kJ mol^{-1}

$\Delta_{fus} H°$ = [27.2] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of the crystal by addition of $\Delta_{fus} H°$ and the difference in enthalpy, H°(650 K) - H°(298.15 K), between the crystal and liquid. Note that the result is based on direct measurements of the enthalpy of mixing of molten LiF and BeF_2 at 1135 K (1).

Heat Capacity and Entropy

Cp° is estimated on the basis of 7.6 cal K^{-1} mol^{-1} by comparison with the liquid phases of LiF, BeF_2 and Li_2BeF_4. A glass transition is assumed at 400 K and below this temperature Cp° is obtained from that of the crystal. The entropy is calculated in a manner analogous to that used for $\Delta_f H°$. Note that the resulting value of S°(900) differs by only 0.08 cal K^{-1} mol^{-1} from that based on measurements of $\Delta_r H°(1135)$ (1) and $\Delta_r G°(900)$ (2) for mixing of molten LiF and BeF_2.

Fusion Data

The composition corresponding to $LiBeF_3$ melts incongruently (3), starting with the eutectic composition of 53 mole percent BeF_2 at 636.6 ± 0.5 K and finishing at a liquidus temperature near 653 K. Just below the melting region, the solid consists of an equimolar mixture of Li_2BeF_4(cr) and BeF_2(high quartz). We arbitrarily adopt 650 K as the hypothetical, congruent melting point of metastable $LiBeF_3$. We estimate $\Delta_{fus} H°$ on the basis of $\Delta_{fus} S°$ = 2.0 cal K^{-1} g-atom^{-1} by comparison with Li_2BeF_4.

Vaporization Data

Mass-spectrometric data (4, 5) for the LiF-BeF_2 system suggest that the vapor consists mainly of BeF_2(g), some $LiBeF_3$(g), and traces of other molecules.

Point Group: [C_{3v}] σ = [3]
Bond Distances: Be-F = [1.40] Å Li-Be = [1.209] Å
Li-F = [1.85] Å
Bond Angles: F-Be F = [120]° Li-Be-F = [90]°
Product of the Moments of Inertia: $I_A I_B I_C = 2.1635 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from $\Delta_r H°(900\ K)$ = 53 kcal mol^{-1} for the reaction: $LiF(g) + BeF_2(g) = LiBeF_3(g)$ reported by Hildenbrand, et al (1).

Heat Capacity and Entropy

The molecular structure was assumed to be pyramidal with Li atom at the top and BeF_3 located at the bottom. Beryllium atom was taken at the center of the equilateral triangle formed by the three F atoms. The Be-F distance was estimated from that of BeF(g). The bond distance of Li-F was taken from Porter and Zeller (2). Vibrational frequencies were estimated by comparison with related fluorides. The principal moments of inertia are: $I_A = I_B = 10.7996 \times 10^{-39}$ and $I_C = 18.5503 \times 10^{-39}$ g cm^2.

PREVIOUS: December 1962 (1 atm) CURRENT: December 1962 (1 bar)

$S°(298.15\ K) = 130.58 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 732.2 \pm 0.2\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -2273.6 \pm 5.0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.995 \pm 2.09\ kJ\ mol^{-1}$

Enthalpy of Formation

Interpolation of the calorimetric enthalpies of mixing of Holm and Kleppa (1) yields $\Delta_r H° = -3.2 \pm 0.1$ kcal mol^{-1} for $2LiF(\ell) + BeF_2(\ell) + Li_2BeF_4(\ell)$ at 1135 K. Reduction with the estimated JANAF functions yields $\Delta_r H° = -4.24 \pm 0.2$ kcal mol^{-1} at 298.15 K for $2LiF(cr) + BeF_2(\ell) + Li_2BeF_4(cr)$, where $BeF_2(\ell)$ is the supercooled liquid. Gross (2) studied the latter reaction calorimetrically and obtained $\Delta_r H° = -5.05 \pm 0.06$ kcal mol^{-1} at 298.15 K. The difference of 0.8 kcal mol^{-1} between the two results is greater than the combined uncertainties but probably is not unreasonable in this case. We adopt the high-temperature results of Holm and Kleppa since the entropy must be calculated by combination of $\Delta_r H°$ with $\Delta_r G°$ obtained at high temperature

Heat Capacity and Entropy

Cp° is taken from the enthalpy study (323-873 K) of Douglas and Payne (3). Their sample was only 98.6% pure and extensive premelting corrections were necessary above 650 K. Thus, Cp° may be more uncertain than usual in this region. The premelting corrections could also be affected by new phase data which show that pure Li_2BeF_4 melts congruently at a temperature 12° lower than assumed in the premelting analysis. The magnitude of the adopted Cp° is confirmed by data by Levina et al. (4) for samples prepared by fusion.

Hitch and Baes (5) reported emf data and activity coefficients which yield $\Delta_r G° = -9.33$ kcal mol^{-1} at 900 K for $2LiF(\ell) + BeF_2(\ell) + Li_2BeF_4(\ell)$. Combining $\Delta_r G°$ with $\Delta_r H° = -4.19$ kcal mol^{-1} derived from data of Holm and Kleppa (1), we obtain $\Delta_r S° = 5.71$ cal $K^{-1}\ mol^{-1}$ at 900 K and $S° = 31.21 \pm 0.5$ cal $K^{-1}\ mol^{-1}$ for $Li_2BeF_4(cr)$ at 298.15 K. This experimental entropy may be compared with 29.8 ± 2 cal $K^{-1}\ mol^{-1}$ estimated by assuming $\Delta_r S° = 0$ for formation form LiF(cr) and $BeF_2(cr)$.

Transition Data

Li_2BeF_4 has a hexagonal unit cell (space group $R\bar{3}$) isotypic with phenacite (6). This structure shows no phase transitions between room temperature and T_{fus} (3, 4, 7), but exposure to traces of moisture at elevated temperatures causes decomposition to LiF and BeO (7, 8). Metastable forms have been reported (4) but not confirmed or identified.

Fusion Data

New electrochemical measurements (9) of the liquidus in the $LiF-BeF_2$ system show that Li_2BeF_4 melts congruently at 459.1 ± 0.2°C with the eutectic point at 458.9 ± 0.2°C and 32.8 mole percent BeF_2. The close proximity of the eutectic explains previous conflicting reports of incongruent (8) and congruent (4, 8) melting. We adopt $T_{fus} = 732.2 \pm 0.2$ K and derive $\Delta_{fus} H°$ = 10.515 kcal mol^{-1} from the difference in smoothed enthalpies for liquid and crystal (3). The uncertainty estimated for $\Delta_{fus} H°$ emphasized the nature of the premelting corrections.

PREVIOUS: June 1966 CURRENT: December 1971

LITHIUM TETRAFLUOROBERYLLATE (Li_2BeF_4) LIQUID M_r = 98.887792

$S°(298.15\ K) = [171.395]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 732.2 \pm 0.2\ K$

$\Delta_f H°(298.15\ K) = [-2241.068]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.995 \pm 2.09\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of the crystal by addition of $\Delta_{fus} H°$ and the difference in enthalpy, $H°(732.2\ K) - H°(298.15\ K)$, between the crystal and liquid. Note that the result is based on direct measurements of the enthalpy of mixing of molten LiF and BeF_2 at 1135 K (1).

Heat Capacity and Entropy

The constant Cp° is derived from enthalpy data (743-873 K) of Douglas and Payne (2). A glass transition is assumed at 500 K and below this temperature Cp° is obtained from that of the crystal. The entropy is calculated in a manner analogous to that used for $\Delta_f H°$. Note that the result is based on measurements of $\Delta_r H°(1135\ K)$ (1) and $\Delta_r G°(900\ K)$ (3) for mixing of molten LiF and BeF_2.

Fusion Data

See the crystal table for details.

Vaporization Data

Mass spectra of vapor effusing from twin-crucible Knudsen cells (4) suggest that the vapor consists of BeF_2, $LiBeF_3$ and traces of other molecules.

Lithium Tetrafluoroberyllate (Li_2BeF_4) $Be_1F_4Li_2$(cr,l)

BERYLLIUM HYDRIDE (BeH) IDEAL GAS M_r = 10.02012

$S°(298.15\ K) = 176.822\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 319 \pm 29\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 321 \pm 29\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^2\Sigma^+$	0	2

$\omega_e = 2058.6\ cm^{-1}$ $\omega_e x_e = 35.5\ cm^{-1}$ $\sigma = 1$
$B_e = 10.308\ cm^{-1}$ $\alpha_e = 0.300\ cm^{-1}$ $r_e = 1.3431$ Å

Enthalpy of Formation

Gaydon (1) selected a value of 2.3 ± 0.3 eV (53 ± 7 kcal mol^{-1}) for D_0^0. Herzberg (2) estimated D_0^0 as being 2.2 eV (50.7 kcal mol^{-1}). Gaydon's (1) value was used in this table.

Heat Capacity and Entropy

Molecular constants were found in Herzberg (2).

BERYLLIUM HYDRIDE, ION (BeH^+) IDEAL GAS M_r = 10.019571

$S°(298.15\ K) = 170.65\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1147.8 \pm 42\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 1156.5 \pm 42\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^1\Sigma$	0	1
$^3\Sigma$	[20000]	[3]

$\omega_e = 2221.7\ cm^{-1}$ $\omega_e x_e = 39.79\ cm^{-1}$ $\sigma = 1$

$B_e = 10.7996\ cm^{-1}$ $\alpha_e = 0.2935\ cm^{-1}$ $r_e = 1.31216$ Å

Enthalpy of Formation

The enthalpy of formation is calculated from the equation $BeH(g) + BeH^+(g) + e^-$ with the JANAF auxiliary data for BeH(g) (1) using an ionization potential of 8.6 ± 0.4 eV (198.34 ± 9.23 kcal mol^{-1}) obtained from Beckett (2).

The dissociation energy, $D_0^0(Be^+-H)$ = 3.2 ± 0.2 eV (73.8 kcal mol^{-1}), has been reported by Gaydon (3). This yields $\Delta_f H°(BeH^+, g, 0\ K)$ = 270.0 kcal mol^{-1} which is in agreement with the value adopted.

Heat Capacity and Entropy

The molecular constants were obtained from the ultraviolet spectroscopic studies by Watson and Humphrey (4). The ground state configuration was given by Herzberg (5). The estimated electronic level and quantum weight were obtained by assuming a $^3\Sigma$ level lies below the first observed excited state ($^1\Sigma$) at 40,000 cm^{-1}.

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -27.4 \pm 10$ kcal mol^{-1}, which corresponds to D_0^0(Be-OH) = 113.9 ± 10 kcal mol^{-1}, is derived from 3rd law analysis of Knudsen-cell mass-spectrometric studies and Knudsen-cell weight-loss studies of several BeOH(g) producing reactions (1-3). The earlier Knudsen-cell mass-spectrometric measurement by Hildenbrand et al. (4) had indicated a minimum absolute value of $\Delta_f H°$(BeOH, g, 298.15 K) = -25 ± 10 kcal mol^{-1}.

Source	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, 3rd law, kcal mol^{-1}	Drift, cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
Inami and Ju (1)	A	3	2422-2485	9.73±0.93	-13.0 ± 2.0	-27.2
	B	3	2422-2485	0.82±0.59	6.2 ± 5.5	-37.3
	C	3	2422-2485	75.56±1.3	-5.3 ± 17	-16.1
	D	3	2422-2485	12.09±1.8	3.6 ± 25	-29.0
Inami and Ju (2)	E	3	2425-2518	22.11±2.1	-21.3 ± 8.6	-27.1
Ko, Greenbaum, and Farber (3)	F	3	2107-2368	106.01±1.40	5.1 ± 1.7	-39.4

Reactions:
A) $BeO(g) + OH(g) = BeOH(g) + O(g)$
B) $Be_2O(g) + OH(g) = BeOH(g) + BeO(g)$
C) $BeO(cr, \beta) + H(g) = BeOH(g)$
D) $Be_2O(g) + H(g) = BeOH(g) + Be(g)$
E) $BeCl(g) + OH(g) = BeOH(g) + Cl(g)$
F) $BeO(cr, \alpha) + 0.5H_2(g) = BeOH(g)$

The average $\Delta_f H°$(BeOH, g, 298.15 K) from the measurements of Inami and Ju (1, 2) is -27.4 kcal mol^{-1}. The $\Delta_{at} H°$(Be-OH, g, 298.15 K) = 115 kcal mol^{-1} from $\Delta_f H°(298.15\ K)$ of -27.4 kcal mol^{-1} appears more reasonable than a $\Delta_{at} H°$(Be-OH, g, 298.15 K) = 127 kcal mol^{-1} from the $\Delta_f H°(298.15\ K)$ of -39.4 kcal mol^{-1}, derived from Ko, Greenbaum, and Farber (3) above. This is based on a comparison of the trends in D_0^0 values of the alkaline earth monofluorides and monochlorides and in the adopted D_0^0 values for the other alkaline earth monohydroxides (5). The analogy between gaseous monohydroxides and monohalides, particularly the monofluorides, has already been recognized (6-9). Accordingly, $\Delta_f H°$(BeOH, g, 298.15 K) = -27.4 ± 10 kcal mol^{-1} is adopted.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear in accordance with the prediction of Walsh (10) and the evidence that the gaseous alkali metal monohydroxides are linear (11-13). By analogy with BeF and BeCl (5) the ground state is assumed to be $^2\Sigma^+$ and the first excited state is estimated at 30000 cm^{-1}.

The Be-O bond distance is estimated to be slightly larger, 0.02 Å, than the Be-F bond distance (5) after noting the close similiarity in bond distance of the alkali metal fluorides and hydroxides. The O-H bond distance is that in water (5).

The Be-O stretching frequency, 1266 cm^{-1}, is estimated to be the same as the Be-F stretching frequency (5, 9). The O-H stretching frequency, 3650 cm^{-1}, is estimated from the alkali metal hydroxides series. The bending frequency, 606 cm^{-1}, is estimated by assuming that the ratio of the bending force constant to the stretching force constant is 0.022, which is the average ratio found in the alkali metal monohydroxides, by Acquista and Abramowitz (9, 13).

The entropy in the present table is higher by 1.83 cal K^{-1} mol^{-1} at 298.15 K and 1.76 cal K^{-1} mol^{-1} at 1000 K than that proposed by Jackson (9); the moment of inertia as calculated by Jackson (9) appears to be in error.

BERYLLIUM HYDROXIDE, ION ($BeOH^+$) IDEAL GAS M_r = 26.018971

$S°(298.15\ K) = [203.9 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 754.70 \pm 50\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 759.93 \pm 50\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[1260] (1)
[600] (2)
[3650] (1)

Ground State Quantum Weight: [1] $\sigma = 1$
Point Group: [$C_{\infty v}$]
Bond Distances: Be-O = [1.38] Å
Bond Angle: Be-O-H = [180]°
Rotational Constant: B_0 = [1.2932] cm^{-1}

Enthalpy of Formation

Using mass spectrometric techniques, Inami and Ju (1) determined the appearance potential of BeOH(g) to be 9.0 ± 0.5 eV (207.55 ± 11.53 kcal mol^{-1}). In the same study, Porter (2) was reported to have said that the appearance potential of a metal hydroxide is expected to be about the same as the corresponding fluoride. In this case, the appearance potential of BeF(g) is 9.1 eV (1), which is within 0.1 eV of the value for BeOH(g). It is also interesting to note that the ionization potential of Be(g) is 9.32 eV (3). We adopt the experimentally determined appearance potential of 9.0 ± 0.5 eV which refers to the process $BeOH(g) + e^- = BeOH^+(g) + 2e^-$. Using auxiliary data (3), we calculate $\Delta_f H°(0\ K) = 180.39 \pm 12.0$ kcal mol^{-1} for $BeOH^+(g)$. This leads to $\Delta_f H°(298.15\ K) = 181.63 \pm 12.0$ kcal mol^{-1}.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear since experimental evidence indicates that the gaseous alkali metal hydroxides are linear (3, 4, 5, 6). In addition, Walsh (7) had predicted that BAH molecules (H=hydrogen atom) with ten or less valence electrons ($BeOH^+$ has 8 valence electrons) will be linear in their ground state. The molecule $BeOH^+$ is isoelectronic with LiOH.

The bond dissociation energy for $BeOH^+$(121.2 kcal mol^{-1}, 3) for the process $BeOH^+(g) = Be^+(g) + OH(g)$ is fairly close to that for BeOH(113.9 kcal mol^{-1}, 3). This suggests a similar bonding in these two molecules. Thus, bond distances are assumed to be the same as those adopted for BeOH(g, 3). The vibrational frequencies are assumed to be similar to those adopted for BeOH(g, 3). The ground state quantum weight is assumed to be the same as that of LiOH(g, 3).

PREVIOUS: December 1960 (1 atm) CURRENT: December 1960 (1 bar)

BERYLLIUM HYDROXIDE, ALPHA (α-$Be(OH)_2$) CRYSTAL M_r = 43.02686

$S°(298.15\ K) = [53.6 \pm 8]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -902.9 \pm 2.0\ kJ\ mol^{-1}$

Enthalpy of Formation

Bear and Turnbull (1) measured the enthalpy of solution of α-$Be(OH)_2$ and Be in 22.6% HF(aq) at 21°C. Combining these results, adjusting to 25°C, and correcting for the small HF concentration differences in the two systems, we calculate $\Delta_r H°(298.15\ K) = -79.16\ kcal\ mol^{-1}$ for the reaction $Be(cr) + 2H_2O(\ell) = Be(OH)_2(\alpha, cr) + H_2(g)$. Using auxiliary data (2, 3), we derive $\Delta_f H°(298.15\ K) = -215.8\ kcal\ mol^{-1}$ for α-$Be(OH)_2$. Since this adopted value is calorimetrically determined and based on well characterized samples, we assign an uncertainty of $\pm$ 0.5 kcal mol^{-1}.

Parker (4) recently reviewed data pertaining to the enthalpy of formation of the beryllium hydroxides. Her analyses were intended to give additional support to the thermochemical values chosen for BeO(cr). Our interpretation would differ slightly due to the fact that our $\Delta_f H°$ value for BeO(cr) is different (by 0.3 kcal mol^{-1} at 298.15 K) from that adopted by Parker (4). Discussed in her review were the enthalpy of solution studies by Fricks and Wullhorst (5) [involving BeO and α-$Be(OH)_2$ in 11.59% HF] and Matignon and Marchal (6, 7) [amorphous $Be(OH)_2$ in 30% HF]. In addition there is also an earlier study by Mulert (8) involving amorphous $Be(OH)_2$ in 20% HF. All these studies are in fair agreement with our adopted value for $\Delta_f H°(298.15\ K)$. These latter studies are thought to be less reliable, however, due to incomplete characterization of the beryllium compounds.

Heat Capacity and Entropy

The heat capacity is assumed to be identical to that of the β-phase. The entropy difference between the α and β phases may be obtained from the solubility data of Fricke and Humme (9). Both crystalline forms of $Be(OH)_2$ were dissolved in varying concentrations of aqueous NaOH. By relating the quantities dissolved, we calculate $\Delta_r G°(303\ K) = -0.5\ (\pm 0.2)\ kcal\ mol^{-1}$ for the process α-$Be(OH)_2 = \beta$-$Be(OH)_2$. Using auxiliary data (2), we find $\Delta_r S°(303\ K) = -0.8\ cal\ K^{-1}\ mol^{-1}$, from which we calculate and adopt $S°(298.15\ K) = 12.8\ cal\ K^{-1}\ mol^{-1}$ for α-$Be(OH)_2$. We assign an uncertainty of $\pm$ 2 cal K^{-1} mol^{-1} to reflect the possible error in this calculation of $\Delta_r S°(303\ K)$.

Phase Data

The structural information for α-$Be(OH)_2$ via x-ray techniques is not complete (1, 9, 10, 11). A tetragonal unit cell has been suggested by Guillemat and Lecocq (11) without supporting data. Bear and Turnbull (1), following this suggestion and using their x-ray data, calculated a crystal density which was consistent with the two experimentally determined values of Fricke and Severin (12, helium densitometry and a pycnometric method). This lends support to the premise that α-$Be(OH)_2$ has a tetragonal unit cell. The alpha phase is metastable.

Decomposition Data

T_{dcm} is calculated as the temperature at which $\Delta_r G°$ is zero for the reaction $Be(OH)_2(\alpha, cr) = BeO(\alpha, cr) + H_2O(g)$.

$S°(298.15\ K) = [50.2 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{dcm} = [366]\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -905.8 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Bear and Turnbull (1) measured the enthalpy of solution of β-$Be(OH)_2$ and Be in 22.6% HF(aq) at 21°C. Combining these results, adjusting to 25°C, and correcting for the small HF concentration differences in the two systems, we calculate $\Delta_r H°(298.15\ K) = -79.89\ kcal\ mol^{-1}$ for the reaction Be(cr) + $2H_2O(\ell)$ = $Be(OH)_2$(β, cr) + $H_2(g)$. Using auxiliary data (2, 3), we derive $\Delta_f H°(298.15\ K) = -216.5\ kcal\ mol^{-1}$ for β-$Be(OH)_2$. Since this adopted value is calorimetrically determined and based on well characterized samples, we assign an uncertainty of ± 0.5 kcal mol^{-1}.

Parker (4) recently reviewed data pertaining to the enthalpy of formation of the beryllium hydroxides. Her analyses were intended to give additional support to the thermochemical values chosen for BeO(cr). Our interpretation would differ slightly due to the fact that our $\Delta_f H°$ value for BeO(cr) is different (by 0.3 kcal mol^{-1} at 298.15 K) from that adopted by Parker (4). Discussed in her review were the enthalpy of solution studies by Fricke and Wullhorst (5) [involving BeO and β-$Be(OH)_2$ in 11.59% HF] and Matignon and Marchal (6, 7) [amorphous $Be(OH)_2$ in 30% HF]. In addition there is also an earlier study by Mulert (8) *involving amorphous $Be(OH)_2$ in 20% HF. These latter three studies are in fair agreement with our adopted value for* $\Delta_f H°(298.15\ K)$ but are thought to be less reliable, however, due to incomplete characterization of the beryllium compounds.

Fricke and Severin (9) and Baur and Lecocq (10) measured the deomposition pressure of water vapor over β-$Be(OH)_2$. Fricke and Severin (9) observed a decomposition temperature at 105°C at a pressure of 100 mm Hg while Baur and Lecocq (10) observed 223°C for the equilibrium with saturated water vapor at 24.2 atm. We reduce the latter data to a standard state value $\Delta_r G°(496\ K) = -3028\ cal\ mol^{-1}$ for the decomposition reaction $Be(OH)_2$(β, cr) → BeO(α, cr) + $H_2O(g)$. The 3rd law analyses for these two decomposition studies are given below where $\Delta_f H°(298.15\ K)$ refers to the enthalpy of formation of β-$Be(OH)_2$.

Source	T/K	Method	kcal mol^{-1} $\Delta_r H°(298.15\ K)$	kcal mol^{-1} $\Delta_f H°(298.15\ K)$
Fricke and Severin (9)	378	Kp	15.27	≥ -218.5
Baur and Lecocq (10)	496	Kp	14.88	≥ -218.1

These values are within 2 kcal mol^{-1} of our adopted $\Delta_f H°(298.15\ K)$ value. The difference may be due to the formation of metastable BeO. Fricke and Severin (9) reported that BeO had a distorted lattice which would suggest a $\Delta_f H°$ value more positive than -145.4 kcal mol^{-1}. Thus, we conclude that these two studies (9, 10) are consistent with our adopted value but are not sufficiently definitive for further consideration.

Heat Capacity and Entropy

The heat capacity is estimated from that for $Mg(OH)_2$ by subtracting the values for MgO(cr) and adding those for BeO(α, cr) (2). The entropy is estimated to be $S°(298.15\ K) = 12.0\ cal\ K^{-1}\ mol^{-1}$. This value is a compromise of values suggested by two different paths. Additive entropy constants of Kelley (11) yield $S°(298.15\ K) = 13.20\ cal\ K^{-1}\ mol^{-1}$ whereas a comparison of entropy differences for the alkali metal and alkaline earth chlorides and hydroxides sugggest values in the range 10.2 to 12.4 cal $K^{-1}\ mol^{-1}$. Our adopted value is the same as that selected by NBS (12).

Phase Data

Bear and Turnbull (1) and Seitz et al. (13), using x-ray powder techniques, determined that β-$Be(OH)_2$ has an orthorhombic structure, the ε-$Zn(OH)_2$ structure. The β-structure is the stable crystalline form for $Be(OH)_2$ whereas the α-structure is metastable.

Decomposition Data

T_{dcm} is calculated as the temperature at which $\Delta_r G°$ is zero for the reaction $Be(OH)_2$(β, cr) → BeO(α, cr) + $H_2O(g)$.

Enthalpy of Formation

The equilibrium reaction BeO(α, cr) + H_2O(g) = $Be(OH)_2$(g) has been studied by several investigators (1-6); all inferred that $Be(OH)_2$ was the major product, but there was no direct proof of this. A 2nd and 3rd law analysis is given below.

**One (or two) point(s) rejected due to a statistical test.

Three of these studies (1-3) were conducted under similar conditions. Each of these investigations (1-3) varied the H_2O(g) flow rate without a detectable change in Kp value. However, one study (3) used a considerable larger flow rate than the others (1, 2). The residence times in all cases were quite comparable. Blauer et al. (4) studied the same system using molecular flow effusion techniques. They reported a larger variation of Kp with surface area, operated at pressures near the upper limits of the molecular flow regime, and encountered unexpected variations of the blank experiments with sample size. Brewer and Elliot (5) also studied the same system but details of the sample are not available and the results show considerable drift. Baur and Lecocq (7) cited a study by Morize et al. (6). No details are given and the results are presented in equation form. It is presumed that the results were obtained in the vicinity of 1673 K.

We adopt $\Delta_f H°(298.15\ K) = -161.7$ kcal mol^{-1} for $Be(OH)_2$(g) which is an average value of three studies (1-3). We assign an uncertainty of ± 9.0 kcal mol^{-1}. The remaining studies are in reasonable agreement with our adopted value (and its uncertainty). As is suggested by Blauer et al. (4), the results of the transpiration studies are greatly affected by surface effects. The larger $\Delta_f H°$ value derived from Blauer et al. (4) is due to a consideration of sample size and surface effects. Thus, it is possible that the earlier studies (1, 2, 3) had not achieved equilibrium.

Hildenbrand et al. (8) examined the BeO-H_2O system at 2300°C mass-spectrometrically and detected BeOH and $Be(OH)_2$. They reported a maximum value for the equilibrium constant for the reaction BeO(g) + H_2O(g) = $Be(OH)_2$(g). From this maximum value, we calculate $\Delta_f H°(298.15\ K) \geq -161.3$ kcal mol^{-1} for $Be(OH)_2$(g). This gives additional support for our adopted value. Qualitative support is found by comparing the dissociation energies of BeOH(g) and $Be(OH)_2$(g) into Be(g) and OH(g); the ratio for the mono- to dihydroxide dissociation is (113.9/256.1) = 0.445; a value which is consistent with similar ratios for the other alkaline earth hydroxides and halides.

Heat Capacity and Entropy

The analogy between gaseous mono- and dihydroxides and gaseous mono- and dihalides, particularly the mono- and difluorides, has been recognized (9-11). The O-Be-O angle is assumed to be the same as the F-Be-F angle (12), i.e. 180°; the Be-O-H angle is assumed to be linear as in MgOH(g) (12). The Be-O bond distance is estimated to be slightly larger, 0.02 Å, than the Be-F distance in BeF_2 (12) after noting the close similarity in the bond distance of the alkali metal fluorides and hydroxides. The O-H bond distance is taken to be the same as in water (12).

The vibrational frequencies are estimated to be the same as in BeF_2 (12) (O-Be-O symmetrical and antisymmetrical stretch and bend) and as in BeOH (12) (O-H stretch and Be-O-H bend).

Jackson (13) has used a different molecular configuration and different vibrational frequencies to estimate S°(298.15 K) = 59.076 cal K^{-1} mol^{-1}. We assign an uncertainty of ± 3 cal K^{-1} mol^{-1} to the adopted entropy.

One vibrational frequency, 649 cm^{-1}, was reported by Farber et al. (14) based on infrared spectral data. We do not adopt this value for the following reasons. It is within 21 cm^{-1} of an adopted value and will not drastically change the entropy. For consistency we estimate all the vibrational frequencies for the alkaline earth dihydroxides in the same manner since the result of Farber et al. (14) is the only reported value.

Enthalpy of Formation

No thermochemical measurements of the enthalpy of formation has been made. The selected value, $\Delta_f H°(BeI, g, 0\ K) = 40.5$ kcal mol^{-1}, is obtained from an analysis of spectroscopic data. The adopted values for the ground state vibrational constants give $D_0^0 = 3.41_4$ eV (78.73 kcal mol^{-1}) via a linear Berge-Sponer extrapolation (1). Based on the ionicity correction developed by Hildenbrand (2), this value adjusts to $D_0^0 = 2.70_7$ eV (62.43 kcal mol^{-1}). We adopt $D_0^0 = 62.4 \pm 10$ kcal mol^{-1} which corresponds to $\Delta_f H°(0\ K) = 40.5 \pm 10.0$ kcal mol^{-1}.

Support for the adopted D_0^0 value is provided by an examination of the trends in the dissociation energies for all alkaline earth monohalides and a comparison of the values for the ratio $\Delta_{at}H°(MX, 298.15\ K)/\Delta_{at}H°(MX_2, 298.15\ K)$ for the alkaline earth halides (3). For the beryllium iodides this ratio is 0.44 which is consistent with the values of this ratio for other alkaline earth halides.

Heat Capacity and Entropy

The ground state vibrational and rotational constants are derived from spectroscopic studies by Murty and Rao (4, 5, 6). The reported value for $\omega_e x_e$ (1.6 cm^{-1}) appears to be inconsistent with the values obtained for other alkaline earth monohalides. By a comparison of $(\omega_e/\omega_e x_e)$ and $x_e u^{1/2}$ values, we estimate $\omega_e x_e = 3.36\ cm^{-1}$ and adopt this value. The reported B_o value is converted to B_e by using a calculated value for α_e. We calculate α_e from the relation $\alpha_e/B_e = 13.2\ (B_e/\omega_e)$ as suggested by Calder and Ruedenberg (7). Initially we use the B_o value in this relationship and then iterate to obtain consistent values for B_e and α_e. We calculate $r_e = 2.132$ Å from B_e. This corresponds well with the 2.12 Å Be-I distance for $BeI_2(g)$ obtained via the electron diffraction study of Akishin et al. (8).

The electronic levels are also from the study by Murty and Rao (4, 5, 6). The possibility of additional levels ($^2\Pi$ and $^2\Sigma^+$) near 15000 cm^{-1} is suggested by a comparison with CaI, SrI, and BaI (3). Including these levels does not change the entropy at 298.15 K but does increase the entropy at 6000 K by 0.7 cal K^{-1} mol^{-1}.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

BERYLLIUM IODIDE (BeI_2) CRYSTAL M_r = 262.82118

$S°(298.15\ K) = [120.5 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 753 \pm 15\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-188.7 \pm 21]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [20.9 \pm 12.6]\ kJ\ mol^{-1}$

Enthalpy of Formation

A direct measurement of the enthalpy of formation has not been made. An estimate of $\Delta_f H°$ is obtained by a method suggested by Parker (1) and used in the $BeBr_2$(cr) table (2). Biltz and Messerknecht (3) have measured the enthalpies of solution of $BeCl_2$(cr) and BeI_2(cr) is aqueous HCl (18.69%). Samples (4) of the dihalides were prepared from reactions of BeO-C mixtures with the halogens at elevated temperatures. We assume that the two dihalides had similar structures, i.e. the α-form (orthorhombic). $\Delta_f H°(BeI_2$, in 18.7% HCl, 298.15 K) is estimated at -109.1 kcal mol^{-1} by combing $\Delta_f H°$ of $BeCl_2$(cr) with $\Delta_f H°(BeCl_2$, cr, α, 298.15 K) = -117.3 ± 0.8 kcal mol^{-1} (2) and twice the difference in $\Delta_f H°(HCl \cdot 8H_2O$, 298.15 K) and $\Delta_f H°$(298.15 K, $HI \cdot 8H_2O$) which is -52.3 kcal mol^{-1} (5). The enthalpy associated with the aqueous anions is assumed to be negligible. Combination of the estimated value for $\Delta_f H°(BeI_2$, in 18.8% HCl, 298.15 K) with $\Delta_f H°$ = -62.5 kcal mol^{-1} (3) gives $\Delta_f H°(BeI_2$, cr, 298.15 K) = -46.6 kcal mol^{-1} which is within 0.6 kcal mol^{-1} of the value suggested by NBS (6). Subsequent measurements by Biltz et al. (7) in less concentrated HCl (1.48%) solution leads to $\Delta_f H°(298.15\ K)$ = -43.6 kcal mol^{-1} by a similar route. We adopt an average value of -45.1 kcal mol^{-1} but emphasize that the uncertainty in $\Delta_f H°$ is much greater than indicated (3 kcal mol^{-1}) by the closeness of these two values. An uncertainty of ± 0.5 kcal mol^{-1} is believed to be more realistic.

Heat Capacity and Entropy

No low-temperature heat capacity or high-temperature enthalpy measurements have been reported. We estimate Cp°(298.15 K) = 16.482 cal K^{-1} mol^{-1} from the reaction $BeCl_2$(cr, α) + 2LiI(cr) = BeI_2(cr) + 2LiCl(cr) by assuming ΔCp° = 0. Similar results are obtained using BeF_2(cr). Cp° values above 298.15 K are assumed to parallel those for α-$BeCl_2$ (2).

Application of the Berthelot principle (8) to the process BaI_2(cr) + Be(cr) → Ba(cr) + BeI_2(cr) suggests S°(298.15 K) = 26.8 cal K^{-1} mol^{-1}. A graphical comparison of the standard entropies for other alkaline-earth dihalides (2) indicates that this value is reasonable. Other estimated values are given by additive entropy constants (9, 27.4 cal K^{-1} mol^{-1}), Brewer (10, 31.0 cal K^{-1} mol^{-1}), and Brewer et al. (11, 25 cal $K^{-1}mol^{-1}$).

For additional information of the heat capacity and entropy, refer to the enthalpy of formation discussion for gaseous BeI_2 (2).

Fusion Data

See the liquid table for details.

Phase Data

Semenenko and Naumova (12) studied the BeI_2 crystal modifications by thermal and x-ray techniques. The study was complicated by the extreme hygroscopicity, high vapor pressures near the melting point, and susceptibility to oxidation on heating by traces of oxygen. As stated by Semenenko and Naumova (12), the sequence of polymorphic conversion and the character of the resulting modifications of BeI_2, which are largely dependent on the heating and cooling conditions, parallel those of $BeCl_2$ (13). They detected thermally transitions at 290°C, 370°C, 470°C, and a melting at 490°C. However, this data does not appear to be fully consistent in terms of crystallographic structures with that proposed by Johnson, Staritzky, and Douglas (14) and Messerknecht and Biltz (15). These latter works suggested two structures with a transition at 350°C.

We assume the similarity with $BeCl_2$ with a transition in the vicinity of 350 - 370°C. Further study is necessary to resolve all possible phases and their structures.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: June 1965 CURRENT: December 1975

$S°(298.15\ K) = [128.999]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 753 \pm 15\ K$

$\Delta_f H°(298.15\ K) = [-178.377]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [20.9 \pm 12.6]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(753 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with the measured value for $BeCl_2$ (1). A glass transition is assumed at 400 K below which the heat capacity is that of the crystal. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Rahlfs and Fischer (2) reported a melting point of 753 K. Semenenko and Naumova (3), using thermal analysis techniques, implied a melting point of 763 K. Since this latter value was derived from a thermogram, it is probable that this value represents a maximum, with the true melting point somewhat lower. We adopt $T_{fus} = 753 \pm 15$ K.

We estimate the enthalpy of melting, $\Delta_{fus}H° = 5.0 \pm 3.0$ kcal mol^{-1}. This estimate includes a contribution for melting (based on the entropy of melting for other alkaline earth dihalides) and a contribution for a phase transition. There is no experimental data available pertaining to the enthalpy of melting.

Vaporization Data

T_{vap} is the temperature at which $\Delta_r G° = 0$ for the process $BeI_2(\ell) = BeI_2(g)$. $\Delta_{vap}H°$ is the corresponding difference in the $\Delta_f H°$ values for the liquid and gas at T_{vap}.

Beryllium Iodide (BeI_2) Be_1I_2(cr,l)

$S°(298.15\ K) = [291.52 \pm 2.1]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -62.5 \pm 33.5\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -64.0 \pm 33.5\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[160] (1)
[175] (2)
873 (1)

Ground State Quantum Weight: [1] $\sigma = 2$
Point Group: $D_{\infty h}$
Bond Distance: Be-I = 2.12 ± 0.05 Å
Bond Angle: I-Be-I = 180° ± 10°
Rotational Constant: B_o = 0.01478 cm^{-1} 0.014778

Enthalpy of Formation

Rahlfs and Fischer (1) have reported measurements of the sublimaiton pressures (578-703 K, 9 pts) for BeI_2. The measurements were complicated by reaction of the diiodide with the quartz apparatus. Assuming the reaction to be $BeI_2(cr) + SiO_2(cr) = SiI_4(g) + 2BeO(cr)$, Rahlfs and Fischer (1) corrected their measured total pressure for the partial pressure of the tetraiodide. A 2nd and 3rd law analysis of their corrected data yields $\Delta_{sub}H°(298.15\ K) = 29.81 \pm 0.29$ kcal mol^{-1} (3rd law) and 28.34 ± 0.74 kcal mol^{-1} (2nd law) with a drift of 2.2 ± 1.1 cal K^{-1} mol^{-1}. We adopt $\Delta_{sub}H°(298.15\ K) = 29.8 \pm 2.0$ kcal mol^{-1}. We have assumed negligible dimer formation. $\Delta_f H°(298.15\ K) = -15.3$ kcal mol^{-1} for $BeI_2(g)$ when the adopted $\Delta_{sub}H°(298.15\ K)$ value is added to the $\Delta_f H°(298.15\ K)$ value for $BeI_2(cr)$.

The drift could be reduced by further adjusting the Gibbs energy functions for the crystal. These functions may be changed by altering the Cp° values and/or the S°(298.15 K) value. Such changes would yield values which are unreasonable when compared to other alkaline earth dihalides. Note also that a similar sublimation study for $BeCl_2$ (2) gives a drift of -1.3 ± 2.6 cal K^{-1} mol^{-1}. We tentatively assume the drift is due to the data rather than our choice of functions.

Heat Capacity and Entropy

Electron diffraction patterns for BeI_2 vapor (3, 4) have been interpreted in terms of a linear configuration, with the latter study reporting the Be-I bond distance as 2.12 A. Other studies also suggest a linear molecule. For example, the electric deflection of mass spectrometricaly detected molecular beams (5) showed that all the beryllium dihalides are linear.

Snelson (6) observed the infrared spectra of BeI_2 in the spectral range 4000-200 cm^{-1} using a matrix isolation technique. Assuming a linear geometry, ν_3 was assigned as 873 cm^{-1}. Snelson (6) estimated a value for ν_2 based on force constant values for the other three beryllium dihalides. The values of ν_1 were calculated using a simple valence force field approximation. We adopt the two estimated and one measured vibrational frequency as reported by Snelson (6). The ground state quantum weight of one is assigned by analogy with $BaCl_2$ (2).

Brewer et al. (7) have tabulated Gibbs energy functions for BeI_2 up to 2000 K. Their values are consistently lower than ours due primarily to their use of a higher bending frequency (ν_2 = 395 cm^{-1}).

Beryllium Nitride (BeN) $Be_1N_1(g)$

BERYLLIUM OXIDE, ALPHA (α-BeO) CRYSTAL M_r = 25.01158

$S°(298.15\ K) = 13.770 \pm 0.21\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 2373 \pm 15\ K\ (\alpha-\beta)$
$T_{fus} = [2821.2 \pm 100]\ K\ (\beta-\ell)$
$T_{fus} = 2780 \pm 100\ K\ (\alpha-\ell)$

$\Delta_f H°(0\ K) = -604.9 \pm 0.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -608.4 \pm 3.3\ kJ\ mol^{-1}$
$\Delta_{trs} H° = [6.694 \pm 1.7]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [79.057 \pm 6.3]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 84.9 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

Parker (1) thoroughly reviewed the data as of 1969 and selected -145.4 ± 0.8 kcal mol^{-1}. She later revised (1) this value to -145.7 ± 0.6 kcal mol^{-1} due to new HF-solution calorimtry on BeF_2(amorphous) performed by Kilday et al. (2). Values of $\Delta_f H°$ from Parker's revised analysis (1) are summarized below. We adopt -145.4 ± 0.8, rather than the revised selection, as a compromise between the indirect results based on Be(cr) and those based on BeF_2(am). The latter depend on $\Delta_f H°$ for HF(n H_2O). Use of the JANAF $\Delta_f H°$ (4) in place of the NBS value (3) causes a change of ± 0.9 kcal mol^{-1} in the results based on BeF_2(am). Recent data for HF suggest that the change could be even larger.

[a]HCl-solution calorimetry of BeO(cr) and Be(cr). [b]HF-solution calorimetry of BeO(cr) and Be(cr). [c]HF-solution calorimetry of BeO(cr) and BeF_2(am) and $\Delta_f H°$ of the latter. [d]Values in parentheses based on $\Delta_f H°$ of HF(n H_2O) from NBS (3) instead of JANAF (4).

Heat Capacity and Entropy

The adopted Cp° and S° below 298.15 K are taken from Furukawa and Reilly (5) who measured Cp° from 16 to 370 K. The authors give a detailed comparison with the earlier data of Gmelin (6, 5 to 75 K) and Kelley (7, 56 to 292 K). Gmelin's results deviate by roughly +20% from 15 to 75 and Kelley's results deviate by about +50% at 56 K, +8% at 100 K and +1% at 200 K. The deviation of Kelley are probably due to the sensitivity limit of his calorimeter and to non-standard state effects of finely powdered BeO.

The adopted Cp° above 298.15 K is from a constrained fit of the Cp° data (5) and enthalpy data of Victor and Douglas (8, 323 to 1173 K), Conway and Hein (9, 2161 to 2365 K) and Shpil'rain et al. (10, 2023 to 2708 K). The latter data show no evidence of transition even though they extend more than 300 K above T_{trs} = 2373 K. Deviations of the data (8) from the adopted enthalpies are <±0.15 % above 373 K and -0.4% at 323 K. Deviations above 2000 K are -0.3 to +0.8% (9) and -1.8 to +0.4% (10) excluding the point at 2266 K (10). Enthalpy measurements not used in the fit deviate by -2.1 to +2.9% (11, 1142 to 2697 K), -17±8% (12, 2273 to 2523 K), -2.1±0.8% (13, 400 to 1100 K) and +0.4 to -0.7% (14, 363 to 1128 K). Cp° data from the cooling-rate method (15) deviate by <2% (1300 to 1700 K) but by -5% at 2000 K.

Transition Data

See the β-crystal table for details.

Fusion Data

See the liquid table for details.

PREVIOUS: December 1974 CURRENT: June 1975

$S°(298.15\ K) = [16.591]\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 2373 \pm 15\ K\ (\alpha+\beta)$

$T_{fus} = [2821.2 \pm 100]\ K\ (\beta+\ell)$

$\Delta_f H°(298.15\ K) = [-601.659]\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 6.694 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [79.057 \pm 6.3]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of BeO(α, cr) by addition of $\Delta_{trs} H°$, since the difference in enthalpy, H°(2373 K) - H°(298.15 K), between the α-and β-phases is zero according to the adopted functions.

Heat Capacity and Entropy

Cp° is taken to be the same as that of BeO(α, cr). Enthalpy data for β-BeO (1) extend from 2377 to 2501 K, a range too short for obtaining an accurate Cp° curve. The enthalpy data deviate from the adopted functions by -0.2 to ± 1.4%. Other enthalpy data (2-4) show no obvious transition to β-BeO; this suggests that experimental uncertainties masked the transition or that these samples failed to transform. S° is calculated in a manner analogous to that used for $\Delta_f H°$.

Transition Data

Studies of x-ray diffraction (5-7), optical properties (6, 8), thermal expansion (1, 9), thermal analysis (10-14), enthalpy (1), and decrepitation of single crystals (6, 9, 15) indicate the existence of a reversible transition near 2100°C. β-BeO is tetragonal with a structure related to rutile (5), while α-BeO is hexagonal close-packed with a wurtzite-type structure (16, 17).

T_{trs} is lower on cooling than on heating. Earlier studies gave temperature differences of about 40° (11, 12), 50° (7) and 80° (14), but a recent DTA study (10) gave T_{trs} values on cooling which were only ~15° below those on heating. T_{trs} = 2107 ± 7°C (IPTS-68) was proposed as a DTA standard temperature because it is reproducible and relatively unchanged by oxide impurities (10). Reported values of T_{trs} on heating include 2100 ± 10°C (1), 2107 ± 7°C (10), 2095°C (11), 2075 ± 15°C (12). 2050-2100°C (7), 2100-2250°C (7), 2144 ± 40°C (14), and 2050 ± 25°C (6). We adopt 2100 ± 15°C.

Reported values of $\Delta_{trs} H°$ include 1.35 ± 0.1 (1), 1.40 ± 0.25 (10), 1.25 ± 0.25 (14), and 0.95 ± 0.3 kcal mol^{-1} (13). The first value is from enthalpy data and the others are from thermal analysis. It is not clear why the transition fails to appear in two other enthalpy studies (2, 3). We adopt $\Delta_{trs} H° = 1.60 \pm 0.4$ kcal mol^{-1} derived from the difference between the enthalpy data for β-BeO (1) and the JANAF enthalpy for α-BeO.

Fusion Data

See the liquid table for details.

PREVIOUS: June 1971 CURRENT: December 1974

$S°(298.15\ K) = [35.931]\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = [2821.2 \pm 100]\ K\ (\beta\text{-}\ell)$
$T_{fus} = 2780 \pm 100\ K\ (\alpha\text{-}\ell)$

$\Delta_f H°(298.15\ K) = [-542.705]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [79.057 \pm 6.3]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 84.9 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of α-BeO by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(2780\ K) - H°(298.15\ K)$, between the α and liquid phases.

Heat Capacity and Entropy

Cp° is taken to be 19 cal K^{-1} mol^{-1} based on the lower two of three enthalpy points (2867-3159 K) measured by Shpil'rain et al. (1). The upper two points yield 24.9 cal K^{-1} mol^{-1}, which is too large in our opinion. Earlier enthalpy data (2, 3) are inadequate for deriving Cp°. Below the assumed glass transition at 1900 K, Cp° is taken to be the same as that of the crystal. S° is calculated in a manner analogous to that used for $\Delta_f H°$.

Fusion Data

Conflicting evidence suggests that the melting points of α- and β-Beo are quite uncertain. Schneider's review (4) listed C six values (T_{fus}/°C, IPTS-48, with dates in parentheses): 2410(1916), 2452(1956), 2508(1937), 2557(1930), 2570(1948) and 2573°. 1913). Subsequent T_{fus} values include 2430 ± 10 (5), 2560 ± 10 (6), 2444 ± 30 (7), 2547 ± 9 (2), 2450 ± 30 and 2470 ± 30°C (8) The reported values fall roughly into two groups near 2450°C and 2560°C. Three enthalpy studies (1-3) avoided the region from 2435°C to 2547°C. Part of the conflict arises because, in most cases, the measurement of T_{fus} of BeO was only an incidental part of the study. Such values are more likely to be in error due to temperature measurement, detection of melting, impurities, volatilization and reaction with the surroundings. The actual discrepancies may be even larger than they appear, since one of the higher T_{fus} values seems to refer to α-BeO which should melt ~40 below β-BeO. Enthalpy data of Kandyba et al. (2) suggest that their sample may have remained as α-BeO, yet they reported T_{fus} = 2547 ± 9°C. In contrast T_{fus} = 2430 ± 10°C was found for β-BeO by Latta et al. (5); their thermal analysis showed both T_{trs} and T_{fus}.

The conflict is epitomized by the two most recent values of T_{fus}, 2430 ± 10°C (5) and 2560 ± 10°C (6). These studies (5, 6) seem to be more satisfactory than their predecessors yet at least one of them has a large bias. They agree (5, 6) on T_{fus} for Al_2O_3, Mo and Ta but differ in opposite directions for BeO and UO_2. Non-stoichiometry could explain the lower $T_{fus}(UO_2)$ reported by Riley (6), but analogous evidence for BeO is lacking. As a compromise, we adopt $T_{fus}(\alpha)$ = 2507°C = 2780 K and calculate $T_{fus}(\beta)$ = 2548°C = 2821.2 K from $\Delta_r G°$ = 0 for BeO(β) → BeO(ℓ).

$\Delta_{fus} H°(\alpha)$ = 20.3 kcal mol^{-1} is calculated by difference from enthalpies (2867-3159 K) of Shpil'rain et al. (1) and the JANAF enthalpy for α-BeO. We assume that BeO(ℓ) reverted to α-BeO and that β-BeO did not form during the drop calorimetry (1). $\Delta_{fus} H°(\beta)$ = 13.895 kcal mol^{-1} is calculated from BeO(β) → BeO(ℓ) at the corresponding T_{fus} using the adopted tables. Enthalpy data of Greenbaum et al. (3) gave $\Delta_{fus} H°$ 19.3 kcal mol^{-1} (phase uncertain) even though both the crystal and liquid data have large negative bias. Ohta and Sata (9) derived $\Delta_{fus} H°$ = 7.6 ± 2.1 kcal mol^{-1} from liquidus data in the binary system BeO-ThO_2. This can be discounted along with other binary data (10, 11) due to the uncertainty in T_{fus}.

Vaporization Data

The vapor over BeO is composed mainly of trimer, tetramer and individual atoms, along with minor amounts of several other molecules.

Enthalpy of Formation

We adopt D_0^o = 104.2 ± 3 and $\Delta_f H°(298.15\ K)$ = 32.6 ± 3 kcal mol^{-1} based on two mass-spectrometric studies (8, 9) analyzed below. The adopted values correspond to the average of the two results for reaction A and also to the average for reaction B. Improved agreement between reactions A and B is due to recalculation of Kp of reaction B using the current table (4) for BeO(α). Our analysis should be compared to the analysis of Brewer and Rosenblatt (10), using "functions based upon calculated levels."

The controversy over D_0^o of alkaline earth oxides has been reviewed in detail (10-12). Uncertainty in the electronic partition function of BeO due to triplet states now is much reduced (2). Gaydon (12) derived spectroscopic values for D_0^o of 91 and 111 kcal mol^{-1} from the X and A states, respectively. D_0^o = 101 kcal mol^{-1} was derived (13) by fitting an electronegativity potential function to the X state.

(8) Chupka (1959)	Knudsen mass spec.	B[b]	1914-2304	6	0.7±0.9	107.3±2	105.9±3	31.9	104.9
(9) Theard (1964)	Knudsen mass spec.	B[b]	2380	1	-	-	104.5±3	33.3	103.5

[a]Reactions: A) BeO(g) + O(g) = Be(g) + O_2(g); B) BeO(g) = Be(g) + O(g).

[b]Recalculated as in (8) assuming $P_{Be} = P_O$ and JANAF values for BeO(α) = Be(g) + O(g).

Heat Capacity and Entropy

Electronic levels (T_0) and vibrational-rotational constants of the observed states are from Rosen (1). Field (2) concluded that calculations (3, 5-7) of the isoconfigurational $A^1\Pi$ - $^3\Pi$ separation should be adequate for estimating the low-lying $^3\Pi$ state. The adopted separation of 1200 cm^{-1} is consistent with analysis (3) of perturbations. We estimate $^3\Sigma^+$ at 16000 cm^{-1} by assuming that it lies 5200 ± 4000 cm^{-1} (4-7) below the isoconfigurational B state. Other predicted states and their vibrational-rotational constants are facilitated by listing the states in the isconfigurational order of MgO (4). Our thermodynamic functions correspond to an "effective" ground state with 1<g<2 instead of g = 3 or 6 (10, 11). This comparison is only approximate since our functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t^i \Sigma\ Q_r^i\ Q_v^i\ g_i\ \exp(-c_2\varepsilon_i/T)$.

Sublimation and Vaporization Data

Mass spectra (8, 9) at 1900-2400 K showed the vapor to consist mainly of Be, O, $(BeO)_3$, and $(BeO)_4$ with small amounts of O_2, Be_2O, BeO and other polymer of BeO. Tetramer, trimer and pentamer become dominant at higher temperatures.

BERYLLIUM SULFATE, ALPHA (α-$BeSO_4$) CRYSTAL M_r = 105.06978

$S°(298.15\ K) = 77.971\ J\ K^{-1}\ mol^{-1}$
$T_{trs1} = 863\ K\ (\alpha + \beta)$
$T_{trs2} = 908\ K\ (\beta + \gamma)$

$\Delta_f H°(0\ K) = -1190.1 \pm 3.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1200.8 \pm 3.3\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = [1.113]\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = [19.552]\ kJ\ mol^{-1}$

Enthalpy of Formation

Bear et al. (1) measured the enthalpies of solution of Be(cr) and $BeSO_4$(cr,α) in concentrated HF and the enthalpy of reaction of H_2SO_4(aq) with $BeSO_4$(aq HF). Combination of these yields reaction (a) below. Taylor et al. (2) measured enthalpies of solution of Be(cr) and $BeSO_4$(cr,α) in H_2SO_4(aq) which yields reaction (b). Marchal (3) measured the total vapor pressure of $BeSO_4$(cr) in the temperature range 863-1103 K. Partial pressures of SO_3(g) were calculated from Marchal's (3) data using JANAF (4) values for the SO_3 - SO_2 equilibrium. 3rd law analysis of these data yields $\Delta_r H°$ for reaction (c) as given below. This was converted to $\Delta_f H°$ for α-$BeSo_4$ using JANAF (4) enthalpies of transitions.

Source	Method	Reaction	T/K	$\Delta_{sol} H_r$ kcal/mol	$\Delta_f H°(298.15\ K)$ kcal/mol
(1)	Calorimetric	(a) Be(cr) + H_2SO_4(109 H_2O) = H_2(g) + α-$BeSO_4$	294	-74.47	-286.65 ± 0.5
(2)	Calorimetric	(b) Be(cr) + H_2SO_4(47.849 H_2O) = H_2(g) + α-$BeSO_4$	298	-76.38	-287.55 ± 0.13
(3)	Kp (973-1083 K)	(c) $BeSO_4(\gamma)$ + BeO(cr) + SO_3(g)	298	43.92	-286.55 ± 0.5

The adopted $\Delta_f H°(298.15\ K) = -287.0 \pm 0.8$ is an average value of reaction (a) and (b). This value is for relatively finely divided crystals of $BeSO_4$ as was indicated by Bear et al. (1).

Heat Capacity and Entropy

Low temperature heat capacities (12-301 K) and high temperature enthalpies (366-864 K) were measured by Taylor, Gardner and Smith (5). These data were joined smoothly at 298.15 K and extrapolated graphically above 864 K. The entropy was obtained from the heat capacities using $S°(12.56\ K) = 0.034\ cal\ K^{-1}\ mol^{-1}$.

Transition Data

Bosik, Novoselova and Simanov (6) observed two endothermic effects at 863-883 K and 908-913 K on the heating and cooling curves of $BeSO_4$(cr); thus we have adopted $T_{trs1}(\alpha\to\beta) = 863$ K and $T_{trs2}(\beta\to\alpha) = 908$ K. $\Delta_{trs1} H°(\alpha\to\beta) = 0.266\ kcal\ mol^{-1}$ was obtained from the single enthalpy point at 863.9 K observed by Taylor, Gardner and Smith (5). $\Delta_{trs2} H°(\beta\to\gamma) = 4.673\ kcal\ mol^{-1}$ was chosen in order to give good agreement with the equilibrium data of Marchal (3).

$S°(298.15\ K) = [79.258]\ J\ K^{-1}\ mol^{-1}$
$T_{trs1} = 863\ K\ (\alpha + \beta)$
$T_{trs2} = 908\ K\ (\beta + \gamma)$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = [-1199.695]\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = [1.113]\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = [19.552]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the alpha phase by adding $\Delta_{trs1} H°$; since the heat capacities of both phases are assumed the same.

Heat Capacity and Entropy

The heat capacity was assumed to be the same as that of alpha phase. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Transition Data

See α-crystal table for details.

PREVIOUS: CURRENT: September 1966

$S°(298.15\ K) = [88.37 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

T_{fus} = Unknown

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-1513.4 \pm 63]\ kJ\ mol^{-1}$

$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(BeWO_4, cr, 298.15\ K) = -361.7\ kcal\ mol^{-1}$, is calculated from $\Delta_r H°(298.15\ K) = -17.1\ kcal\ mol^{-1}$ for $BeO(cr) + WO_3(cr) \rightarrow BeWO_4(cr)$. The value of $\Delta_r H°(298.15\ K)$ is assumed to be the same as that for $MgO(cr) + WO_3(cr) \rightarrow MgWO_4(cr)$, using -143.7, -143.1, -201.5, and -362.3 kcal mol^{-1} for the enthalpies of formation of MgO(cr), BeO(cr), $WO_3(cr)$ and $MgWO_4(cr)$, respectively.

Heat Capacity and Entropy

Heat capacities are estimated by comparison with those of $CaWO_4(cr)$ (1), BeO(cr) (2), and CaO(cr) (3).

The entropy, $S°(298.15\ K) = 21.12\ cal\ K^{-1}\ mol^{-1}$, is calculated from $\Delta S°(298.15\ K) = -0.4\ cal\ K^{-1}\ mol^{-1}$ for $BeO(cr) + WO_3(cr) \rightarrow BeWO_4(cr)$. The value of $\Delta S°(298.15\ K)$ is assumed to be the same as that for $MgO(cr) + WO_3(cr) \rightarrow MgWO_4(cr)$, using 6.44, 3.38, 18.14 and 24.18 cal $K^{-1}\ mol^{-1}$ for MgO(cr), BeO(cr), $WO_3(cr)$ and $MgWO_4(cr)$, respectively.

PREVIOUS: June 1963 CURRENT: March 1967

$S°(298.15\ K) = [37.03 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 863\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -234.3 \pm 8.8\ kJ\ mol^{-1}$

Enthalpy of Formation

Von Wartenberg (1) has measured the enthalpy of solution of Be and BeS in H_2SO_4. The difference between these two enthalpies gives $\Delta_r H°(353\ K) = -51.35 \pm 2.1\ kcal\ mol^{-1}$ for the reaction $Be(cr) + H_2S(g) \rightarrow BeS(cr) + H_2(g)$. Using auxiliary JANAF (2) data we calculate $\Delta_f H°(BeS, cr, 298.15\ K) = -56.0 \pm 2.1\ kcal\ mol^{-1}$. This is in agreement with the value for the enthalpy of formation preferred by NBS (3).

Heat Capacity and Entropy

No low-temperature heat capacity or high-temperature enthalpy measurements have been reported. We estimate $C_p°(298.15\ K) = 8.13\ cal\ K^{-1}\ mol^{-1}$ from the reaction $BeO(cr, \alpha) + MgS(cr) = BeS(cr)$ by assuming $\Delta C_p° = 0$ (2). Comparison of this value with $C_p°$ data for all the alkaline earth oxides and sulfides (2) suggests that our estimate is reasonable. $C_p°$ data above 298.15 K are estimated graphically by comparison with α- and β-BeO (2).

Several methods of estimation predict that the value of $S°(298.15\ K)$ should lie near $8.85\ cal\ K^{-1}\ mol^{-1}$. A graphical comparison of the standard entropies for other alkaline-earth oxides and sulfides suggest values for $S°(298.15\ K)$ in the range $9\text{-}10\ cal\ K^{-1}\ mol^{-1}$ while additive entropy constants (4) give 6.8 (Kelly's) and 9.3 (Latimer's) $cal\ K^{-1}\ mol^{-1}$. Literature estimates have included (in $cal\ K^{-1}\ mol^{-1}$) 7.4 (5), 8.0 (6), and 8.4 (7). We adopt $S°(298.15\ K) = 8.85 \pm 1.0\ cal\ K^{-1}\ mol^{-1}$ based on cation increments for a series of beryllium and magnesium compounds.

Fusion Data

No literature melting data are available. BeO and BeS have a different crystal structure (cubic, zincblende type) than the remaining alkaline-earth oxides and sulfides (cubic, NaCl type).

Enthalpy of Formation

No experimental data are available on BeS(g). We estimate D_0^0(BeS, g) by the method of Hauge and Margrave (1) based on data involving known bond energies and force constants of the gaseous diatomic oxides and sulfides. Based on dissociation energies of the alkaline earth monoxides, taken from Srivastava (2), dissociation energies of the alkaline earth sulfides and force constants calculated from JANAF data (3), we calculate D_0^0(BeS, g) = 80 ± 10 kcal mol^{-1}. A normal linear-Birge-Sponer extrapolation of the ground state yields D_0^0(BeS, g) = 115 kcal mol^{-1}. After correcting for ionic character (8) and for excited state products D_0^0(BeS, g) = 76 kcal mol^{-1}. These values are very uncertain. See the discussion of MgS(g) (3). We adopte D_0^0(BeS, g) = 80 ± 15 kcal mol^{-1}. Using auxiliary JANAF data (3), we calculate $\Delta_f H°$(BeS, g, 298.15 K) = 63 ± 15 kcal mol^{-1}.

Heat Capacity and Entropy

The spectroscopic constants of the observed states taken from Cheetham et al. (4) are corrected to account for the natural abundances of the elements. Other low-lying electronic states and their vibrational-rotational constants are estimated in isoconfigurational groups by analogy with BeO (5) and from trends observed in the known states of the other alkaline-earth oxides and sulfides (3). Uncertainty in the energy and molecular constants for the estimated states may contribute as much as 2-3 cal K^{-1} mol^{-1} to the entropy above 3000 K.

The splitting between the $A^1\Pi$ and a $^3\Pi$ states, ~1200 cm^{-1}, is based on trends in the triplet-singlet splitting observed by Field (6) for the alkaline-earth oxides. The Hartree-Fock calculations of Verhaegen and Richards (7) support this. Their theoretical signlet-triplet splitting should be reasonably accurate even though the absolute energies are biased. The thermodynamic functions are calculated using first-order anharmonic corrections to Q_r and Q_v in the partition function $Q = Q_t^i \Sigma\ Q_r^i\ Q_v^i\ g_i \exp(-c_2\varepsilon_i/T)$.

*Estimated as explained below.

Enthalpy of Formation

The adopted value of the ground state dissociation energy for $Be_2(g)$, D_0^0 = 8.535 ± 0.879 kJ mol^{-1}, was determined via a high level quantum mechanical calculation by Lengsfield, et al. (1). Using this value and the recommended value for $\Delta_f H°(Be, g, 0\ K)$ = 319.8 kJ mol^{-1} from CODATA (2), we calculate the adopted value of $\Delta_f H°(Be_2, g, 0\ K)$ = 631.1 ± 6.3 kJ mol^{-1}.

Heat Capacity and Entropy

The thermal functions were calculated using a direct summation technique analogous to the alkali dimers and diatomic halogens (12). As in the diatomic fluorine case, the values of G(v), B_v, and D_v were directly input into the calculation. Values of 9 bound vibrational energy levels for the $^1\Sigma_g^+$ ground state were determined from a high level ab initio quantum mechanical calculation (including full configuration interaction) (3). However, a recent spectroscopic determination by Bondybey (4) gave a value for $\Delta G_{1/2}$ = 224 cm^{-1} which is 1.21 times larger than the corresponding value from the theoretical calculation. We therefore adopt $\omega G_{1/2}$ = 224 cm^{-1} and increase the rest of the theoretically determined vibrational spacings by the same factor. These scaled G(v) are given in the table above. Since the theoretical binding energy of Harrison and Handy (3) may also be too small, we adopt the value calculated by Lengsfield et al. (1). The adopted values of B_v are estimated using the correlation of Calder and Ruedenberg (5). Since a plot of $\omega G_{v+1/2}$ vs. $\dot{v}$ exhibits two linear regions ($0 \leq v \leq 3$ and $4 \leq v \leq 8$), the value of B_e used to estimate σ_e in the $4 \leq v \leq 8$ region is reduced from 0.593 to 0.39. This is done in order to assure a smoothly decreasing B_v as v increases. The D_v parameters are determined from the estimation method of Herzberg (6) where we use the first order D_e term only.

The rotational levels are extrapolated to high J values according to the method of Khachkuruzov (7) who proposed a simpler form of Wooley's method (8). The rotational levels are weighted in accordance with the nuclear spin-rotation interaction (9) as follows: even J weight = 0.625, odd J weight = 0.375. The so-called quasibound rotational levels were not included in the calculation. No suitable spectroscopic information exists for any of the excited states of Be_2. It should be noted that the inclusion of $^3\Sigma_u^+$ and $^3\Pi_g$ states in the range Te ≥ 5000 cm^{-1} as proposed by Jones (10) would cause our calculated thermal functions to be deficient at temperatures greater than about 2000 K (13). Due to the extremely shallow well of the ground state, most Be_2 molecules will probably exist in an excited state at temperatures T ≥ 1000 K. The calculated S°(298.15 K) is 5.41 J K^{-1} mol^{-1} smaller than the value adopted by Glushko, et al. (11).

Ground State Quantum Weight: 1 α = 4
Point Group: [D_{2h}]
Bond Distances: Be-Cl = [1.7]Å Be-Cl' (in ring) = [1.8]Å
Bond Angles: Cl'-Be-Cl' (in ring) = [88]° Cl'-Be-Cl = [136]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [2.6276 X 10^{-112}] g^3 cm^6

Enthalpy of Formation

The enthalpy of formation was estimated by assuming that the concentration of dimer in equilibrium with the monomer was ~5% at 500 K as reported by Hildenbrand, Theard, Murad and Ju (1), giving an effective K_p = 5.5 x 10^{-4} for $2BeCl_2(g) \rightarrow Be_2Cl_4(g)$ at 500 K.

Heat Capacity and Entropy

The structure was assumed planar with a D_{2h} symmetry, the bond lengths were estimated from the values for $BeCl_2(g)$, a lengthening being assumed in the ring. The frequencies were estimated using K_2Cl_2 as a basis for the ring vibrations. Two polymeric frequencies had been observed by Snelson (2). These were observed in matrix isolated $BeCl_2$ gas and were ascribed to polymeric species on account of thier warm up behavior. They are here assigned to the B_{3u} asymmetric stretching mode and the B_{1u} symmetric out of plane wag of the non-ring chlorines. The order of the frequencies listed above is arbitrary and not related to their species type. The principal moments of inertia are: I_A = [18.4088 x 10^{-39}] g cm^2, I_B = [110.6214 x 10^{-39}] g cm^2 and I_C = [129.0303 x 10^{-39}] g cm^2.

Bond Angles: O-Be-F = [180]° Be-O-Be = [150]°

Product of the Moments of Inertia: $I_A I_B I_C = [2.5549 \times 10^{-114}]\ g^3\ cm^6$

Enthalpy of Formation

Efimenko (1) has studied mass spectrometrically the reaction BeO(cr) + BeF_2(g) = Be_2OF_2(g) and also reported two sets of equilibrium constants. Using JANAF thermal functions, the enthalpy of reaction has been calculated from those reported equilibrium constants by the 2nd law and the 3rd law methods.

	Number of Measurments	T/K	$\Delta_r H°$(298.15 K), kcal/mol 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
1st Set	13	1570-1891	41.448 ± 3.04	41.981	0.408 ± 1.726
2nd Set	21*	1872-2195	42.553 ± 0.70	42.714	0.015 ± 0.359

*There are 4 points rejected due to failure of statistical test.

A weighted average value, $\Delta_r H°(298.15\ K) = 42.70\ kcal\ mol^{-1}$, was chosen for the enthalpy of reaction. The enthalpy of formation $\Delta_f H°(Be_2OF_2, g, 298.15\ K) = 287.9 \pm 5\ kcal\ mol^{-1}$ was calculated from the selected enthalpy of reaction, using $\Delta_f H°(BeO, cr, 298.15\ K) = 143.1\ kcal\ mol^{-1}$ and $\Delta_f H°(BeF_2, g, 298.15\ K) = 187.5\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The adopted "V" shape molecular structure with nine fundamental vibrational frequencies was obtained from an estimation by Mann (3). The bond distance Be-O and Be-F were estimated to be the same as those in BeO(g) and BeF_2(g), respectively. The principal moments of inertia are: $I_A = 1.0103 \times 10^{-39}$, $I_B = 49.7842 \times 10^{-39}$ and $I_C = 50.7946 \times 10^{-39}$ g cm^2.

PREVIOUS: June 1966 (1 atm) CURRENT: June 1966 (1 bar)

BERYLLIUM OXIDE (Be_2O) IDEAL GAS M_r = 34.02376

$S°(298.15\ K) = [220.8]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -64 \pm 42\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -63 \pm 42\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	g_i
[1100]	(1)
[500]	(2)
[1600]	(1)

Ground State Quantum Weight: [3] $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Be-O = [1.4] Å

Bond Angle: Be-O-Be = [180]°

Rotational Constant: B_0 = [0.477178] cm^{-1}

Enthalpy of Formation

Hildenbrand, Theard, and Ju (1) have reported the enthalpy of formation. Equilibrium constants were determined in a mass spectrometer for the reactions $2BeO(cr) + Be_2O(g) + O(g)$ - (1); $2BeO(g) + Be_2O(g) + O(g)$ - (2); and $Be_2O_2(g) + Be_2O(g) + O(g)$ - (3). Using our own Gibbs energy functions we obtain $\Delta_f H°(Be_2O, g, 298.15\ K)$ = 13.1, -14.5, and -16.7 kcal mol^{-1}, all ± 10; the 2nd law treatment of reaction 1 gives -18.3 ± 10 kcal mol^{-1}. We adopt a median value -15 ± 10 kcal mol^{-1}.

Heat Capacity and Entropy

Buchler, Stauffer, Klemperer and Wharton (2) have shown Li_2O to be linear. Also Walsh (3) predicted that AB_2 molecules with less than 16 bonding electrons would be linear. Thus Be_2O was taken to be linear and symmetrical, with a Be-O bond length of 1.4 Å, which is a little longer than in BeO(g). The vibrational frequencies were estimated by taking ν_3 to be larger than the stretch in BeO(g) and then calculating ν_1 from the valence force field assumption. The bending force constant was estimated as 1/20th of the stretching force constant. The two outermost electrons were considered unpaired and so gave a $^3\Sigma$ ground state.

Bond Distance: Be-O = [1.63] Å
Bond Angles: Be-O-Be = [90]° O-Be-O = [90]°
Product of the Moments of Inertia: $I_A I_B I_C = [3.0972 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

Chupka, Berkowitz, and Giese (1) studied the temperature dependence of the $(BeO)_2^+$ ion in a mass spectrometer and obtained a 2nd law enthalpy of vaporization of 172 ± 8 kcal mol^{-1} at 2150 K. No correction was made for fragmentation of higher polymers and this is reflected in the uncertainty. We adopted an enthalpy of sublimation of 178 kcal mol^{-1} in order to match more closely the equilibrium constant found by Chupka, et al. (1). However, it was not possible to alter either the enthalpy or entropy sufficiently to obtain exact agreement, the predicted pressure being too high by a factor of 20.

Heat Capacity and Entropy.

A planar ring configuration was assumed which has six vibrational frequencies of the type $2A_{1g}$, B_{1g}, B_{1u}, B_{2u}, and B_{3u}. These were estimated by comparison with $(LiO)_2$ for which values have been calculated by White, Seshadri, Dever, Mann, and Linevsky (2). It seems unlikely that any other structure than that of a ring is possible, as, in order to approach the observed equilibrium constant an even lower entropy is needed. A non-linear chain would have a higher entropy due to the change in symmetry number and the two odd electrons. A linear chain would have approximately the same entropy due to cancellation of opposite effects. The vibrational frequencies were also made as high as possible by normalizing them using B_{3u} equal to the BeO stretch in BeO(g). The bond length was taken as the sum of the covalent radii of O and Be, which is in general agreement with other polymeric structures which generally increase in bond length by 10-20% in going from monomer to polymer. The bond angle was chosen arbitrarily, however, changes in the angle would change the entropy less than 1 cal K^{-1} mol^{-1}.

The principal moments of inertia are: $I_A = 7.0589 \times 10^{-39}$, $I_B = 3.9761 \times 10^{-39}$, and $I_C = 11.0350 \times 10^{-39}$ g cm^2.

Beryllium Oxide ((BeO)$_2$) Be_2O_2(g)

BERYLLIUM SILICATE (Be_2SiO_4) CRYSTAL M_r = 110.10746

$S°(298.15\ K) = 64.190 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1833\ K$

$\Delta_f H°(0\ K) = [-2105 \pm 29]\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-2117 \pm 29]\ kJ\ mol^{-1}$

Enthalpy of Formation

The $\Delta_f H°(298.15\ K)$ was estimated from the $\Delta_r H°(298.15\ K)$ of Mg, Ca and Ba oxides with SiO_2 given by Kelley (1) and from the $\Delta_f H°(298.15\ K)$ of BeO(cr) and SiO_2(cr) in the JANAF tables (2). The $\Delta_r H°(298.15\ K) = 0 \pm 7$ kcal mol^{-1} was estimated for the reaction 2BeO(cr) + SiO_2(cr) → Be_2SiO_4(cr).

Heat Capacity and Entropy

At low temperatures C_p was used from Kelley (4). Above 298.15 K C_p values were estimated by summation of the component oxides using the JANAF tables (2), BeO and SiO_2. The entropy was calculated at 54.7 K using the Debye and Planck-Einstein functions D(422/T) + 2E(527/T) given by Kelley (4). The value of $S°(54.7\ K) = 13.59$ cal $K^{-1}\ mol^{-1}$.

Fusion Data

The incongruent melting point was taken from Kubaschewski and Evans (5).

BERYLLIUM NITRIDE ALPHA (α-Be_3N_2) CRYSTAL M_r = 55.04994

$S°(298.15\ K) = 34.129\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2473\ K$

$\Delta_f H°\ (0\ K) = -580.9 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -588.3 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [129.3]\ kJ\ mol^{-1}$

Enthalpy of Formation

Gross, Hayman, Greene and Bingham (1) have measured the enthalpy of Chlorination of α-Be_3N_2 to α-$BeCl_2$, and the enthalpy of reaction of Be with ammonia. The chlorination reaction (A) α-$Be_3N_2(cr) + 3Cl_2(g) \rightarrow 3\ \alpha$-$BeCl_2(cr) + N_2(g)$ had a $\Delta_r H°(298.15\ K) = -210.3 \pm 0.4\ kcal\ mol^{-1}$ which, combined with the value of $-117.1 \pm 0.4\ kcal\ mol^{-1}$ for α-$BeCl_2$ reported in the same paper, yields $\Delta_f H°(\alpha\text{-}Be_3N_2, cr, 298.15\ K) = -141.0 \pm 1.6\ kcal\ mol^{-1}$. Reaction (B) $3Be(cr) + 2\ NH_3(g) \rightarrow \alpha$-$Be_3N_2(cr) + 3\ H_2(g)$ had a $\Delta_r H°(298.15\ K) = -214.6 \pm 0.3\ kcal\ mol^{-1}$, which, combined with the JANAF (2) value for $NH_3(g)$, yields $\Delta_f H°(\alpha\text{-}Be_3N_2, cr, 298.15\ K) = -140.3 \pm 0.3\ kcal\ mol^{-1}$. A weighted mean value of the above two determinations is adopted.

The decomposition $Be_3N_2(cr) = 3\ Be(g) + N_2(g)$ has been studied by Yates, Greenbaum and Farber (3) using the torsion effusion technique. The same decomposition has also been investigated by Hoenig (4) using the Knudsen technique. An analysis of these data sets by 2nd and 3rd law methods is given below.

Source	T/K	Points	$\Delta_r H°(298.15\ K)$ kcal mol^{-1} 2nd law	3rd law	Drift cal $K^{-1}mol^{-1}$	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

*Points rejected due to failure of statistical test.

The data of Yates et al. (3) are seen to be in good agreement with the adopted $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

The low temperature heat capacity of α-Be_3N_2 has been measured, 25 - 310 K, by Justice (5). These measurements are joined smoothly with the high temperature enthalpies reported by Douglas and Payne (6). Above 1200 K the values were smoothly extrapolated to a limiting value of 6.2 cal K^{-1} g-$atom^{-1}$. The entropy at 298.15 K was calculated by integration of the low temperature data based on $S°(25\ K) = 0.002\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

See the liquid table for details.

BERYLLIUM NITRIDE (Be_3N_2) LIQUID M_r = 55.04994

$S°(298.15\ K) = [39.457]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2473\ K$

$\Delta_f H°(298.15\ K) = [-486.979]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [129.3]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of $Be_3N_2(\ell)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2473 K) − H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated to be constant and slightly greater than the maximum for $Be_3N_2(cr)$. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point was reported by Fichter and Brunner (1). The enthalpy of melting is calculated on the assumption that each g-atom contributed 2.5 cal K^{-1} mol^{-1} to $\Delta_{fus}S°$.

Ground State Quantum Weight: [1] σ = [6]
Point Group: [D_{3h}]
Bond Distance: Be-O = [1.63] Å
Bond Angles: Be-O-Be = [120]° O-Be-O [120]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [9.0703 x 10^{-114}] $g^3\ cm^6$

Enthalpy of Formation

Chupka, Berkowitz, and Giese (1) measured the change in the intensity of the $(BeO)_3^+$ ion with temperature and obtained a 2nd law enthalpy of vaporization of 161 ± 6 kcal mol^{-1} at 2150 K. The uncertainty is large because of an approximate correction of 8 kcal mol^{-1} and the neglect of fragmentation effects. We adopted an enthalpy of sublimation at 2150 K of 163 kcal mol^{-1} in order to bring the equilibrium vapor pressure into agreement with that measured by Chupka, et al. (1).

Heat Capacity and Entropy

The assumed D_{3h} symmetry implies eight vibrational frequencies of the types $2A_1'$, A_2', A_2'', 3E' and E_2''. The frequencies were estimated by comparison with the values for the $B_3O_3(O^-)_3$ skeleton as given by Parsons (2) and the partial assignment of Boroxine by Gupta and Porter (3). The bond length was taken as that in $Be_2O_2(g)$, while the bond angle was arbitrarily taken as 120°. The principal moments of inertia are: $I_A = I_B = 16.5525 \times 10^{-39}$ and $I_C = 33.1050 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

Chupka, Berkowitz, and Giese (1) measured the variation of intensity of the $(BeO)_4^+$ ion with temperature in a mass spectrometer. They reported a 2nd law enthalpy of vaporization of 177 ± 8 kcal mol^{-1} at 2150 K, which included an approximate correction of 9 kcal mol^{-1}, and this value was adopted here.

Heat Capacity and Entropy

The assumed D_{4h} structure has 14 vibrational frequencies of the type $2A_{1g}$, A_{2g}, $2B_{2g}$, E_g, A_{2u}, B_{2u}, B_{1u}, and $3E_u$. The frequencies were estimated by comparison with $(BeO)_3$ and cyclobutane from Rathjens, Freeman, Gwinn, and Pitzer (2). The estimated structure and frequencies gave an entropy which was in excellent agreement with the experimental enthalpy and equilibrium constant determined by Chupka, et al. (1).

The bond lengths were taken equal to those in $Be_2O_2(g)$ and the angles were chosen so that O-Be-O was almost linear. The principal moments of inertia are: $I_A = I_B = 38.2258 \times 10^{-39}$ and $I_C = 76.4515 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

Chupka, Berkowitz, and Giese (1) measured the variation in intensity of the $(BeO)_5^+$ ion with temperature in a mass spectrometer. They calculated a 2nd law enthalpy of vaporization of 193 ± 12 kcal mol^{-1} at 2150 K; the uncertainty reflects the inclusion of an approximate correction of 10 kcal mol^{-1}. This value was adopted here.

Heat Capacity and Entropy

The assumed D_{5h} structure has 14 vibrations of the type $2A_1'$, A_2', $3E_1'$, $4E_2'$, A_2'', E_1'', and $2E_2''$. These were estimated by comparison with similar motions in other ring structures including $(BeO)_3$ and $(BeO)_4$. The estimated structure and frequencies gave an entropy in good agreement with the experimental enthalpy and equilibrium constant determined by Chupka, et al. (1).

The bond length was assumed to be the same as in $Be_2O_2(g)$ and the angles were chosen so as to make O-Be-O almost linear. The principal moments of inertia are: $I_A = I_B = 70.3689 \times 10^{-39}$ and $I_C = 140.7378 \times 10^{-39}$ g cm^2.

Bond Angles: Be-O-Be = [110]° O-Be-O = [190]°

Product of the Moments of Inertia: $I_A I_B I_C = [3.1282 \times 10^{-111}]\ g^3\ cm^6$

Enthalpy of Formation

Chupka, Berkowitz, and Giese (1) measured the temperature dependence of the $(BeO)_6^+$ ion in a mass spectrometer. They calculated a 2nd law enthalpy of vaporizaion of 203 ± 15 kcal mol^{-1} which was adopted here. The uncertainty reflects in part an approximate correction of 10 kcal mol^{-1} and the small observed intensities.

Heat Capacity and Entropy

The assumed symmetry D_{6h} has 20 vibrational frequencies of the type $2A_{1g}$, A_{2g}, B_{1g}, B_{2g}, E_{1g}, $4E_{2g}$, A_{2u}, $2B_{1u}$, $2B_{2u}$, $3E_{1u}$, and $2E_{2u}$. The frequencies were estimated by comparison with similar motions in other ring molecules including benzene, $(BeO)_3$ and $(BeO)_4$. The assumed structure and vibrational frequencies gave an entropy in good agreement with the experimental enthalpy and equilibrium constant determined by Chupka, et al (1). The bond length was taken equal to that in $Be_2O_2(g)$. The angles were chosen so that the O-Be-O angle was almost linear but with the Be-O-Be angle less than 120°. The principal moments of inertia are: $I_A = I_B = 116.0793 \times 10^{-39}$ and $I_C = 232.1586 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

The adopted value for the enthalpy of formation of Br(g) is derived from the spectroscopically determined dissociation energy of Br_2(g) as reported by Barrow et al. (1, 2). This value is also recommended by Brewer and Winn (3) and Huber and Herzberg (4). The adopted value, D_0^0 = 15895.6±0.02 cm^{-1} (190.154±0.001 kJ mol^{-1}), has been corrected for the natural isotopic abundance from the dissociation energies of $^{79}Br_2$ and $^{81}Br_2$. The convergence limit in the absorption spectrum of the $^3\Pi_{0^+u}$ - $^1\Sigma_g^+$ system corresponds to dissociation to a ground state bromine atom ($^3P_{3/2}$) and a bromine atom in the $^3P_{1/2}$ excited state.

Using earlier data, the CODATA recommended value (5) was calculated using D_0^0 (^{79}Br ^{81}Br) = 15893.1±2 cm^{-1} based on Horsley and Barrow (6) and Sitterly (7). LeRoy (8) recalculated the dissociation energy from these data; his result is correct only if Horsley and Barrow (6) missed many upper rotational levels of higher vibrational states in their interpretation of the absorption spectra. Subsequent to these initial CODATA evaluation, LeRoy and Bernstein (9), using the band origins obtained by Horsley and Barrow (6), derived D_0^0 (^{79}Br ^{81}Br) = 15895.5±0.5 cm^{-1}.

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore (10, 11). Only two levels are included in the calculation. All other levels (observed and predicted) lie above 63430 cm^{-1}. Our calculations indicate that any reasonable method of filling in the missing levels and cutting off the summation in the partition function (12) has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels. Therefore, we list only the ground state and the first excited state. Extension to higher temperatures may require consideration of the higher excited states and utilization of different fill and cutoff procedures.

The thermodynamic functions at 298.15 K are in agreement with recent CODATA recommendations (13) except for two minor differences. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the monatomic halogens arise due to the use of slightly different values for the relative atomic mass and for R; this table uses R = 8.31441 J K^{-1} mol^{-1}. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren et al. (14), Gurvich et al. (15) and Wagman et al. (16). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which are based on the 1981 scale (17) and the 1973 values (18), respectively.

PREVIOUS: June 1974 (1 atm) CURRENT: June 1982 (1 bar)

BROMINE, ION (Br^+) IDEAL GAS M_r = 79.90345

$IP(Br^+, g) = 175870 \pm 10\ cm^{-1}$

$S°(298.15\ K) = 176.872 \pm 0.005\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1256.95 \pm 0.13\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [1257.091]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^3P_2$	0.0	5
$^3P_1$	3136.4	3
$^3P_0$	3837.5	1
$^1D_2$	12089.1	5
$^1S_0$	27867.1	1

Enthalpy of Formation

$\Delta_f H°(Br^+, g, 0\ K)$ is calculated from $\Delta_f H°(Br, g, 0\ K)$ (1) using the spectroscopic value of IP(Br) = 95284.8±0.5 cm^{-1} (1139.86±0.01 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ mol^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization potential and appearance potential data.

$\Delta_f H°(Br^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Br, g, 0\ K)$ by using IP(Br) with JANAF (1) enthalpies, $H°(0\ K)-H°(298.15\ K)$, for Br(g), $Br^+(g)$, and $e^-(g)$. $\Delta_f H°(Br \rightarrow Br^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the lowest four excited states; the next lowest level is approximately 93927 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and four excited states, with the energy of these states taken from recent study by Moore (2). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, fundamental constants, and the position of the four lowest excited states. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (7).

BROMINE, ION (Br^-) IDEAL GAS M_r = 79.90455

EA(Br, g) = 3.365 ± 0.003 eV

$S°(298.15\ K)$ = 163.491 ± 0.005 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = -206.8 ± 0.5 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [-219.008] kJ mol^{-1}

Electronic Level and Quantum Weight

State	ϵ_i, cm^{-1}	g_i
$^1S_0$	0.0	1

Enthalpy of Formation

$\Delta_f H°(Br^-, g, 0\ K)$ is calculated from $\Delta_f H°(Br, g, 0\ K)$ (1) using the adopted electron affinity of EA(Br) = 3.363±0.003 eV (324.671±0.289 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (10), is based on plasma absorption and plasma emission studies (5, 6). Additional information on $Br^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 10), Rosenstock et al. (3) and Massey (4).

$\Delta_f H°(Br^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Br, g, 0\ K)$ by using EA(Br) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Br^-(g)$, Br(g), and $e^-(g)$. $\Delta_r H°(Br^- \rightarrow Br + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Br^-(g)$ is given by Hotop and Lineberger (2, 10), Rosenstock et al. (3) and Massey (4). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

The entropy at all temperatures (0-6000 K) agrees within 0.001 J K^{-1} mol^{-1} with the values of Gurvich et al. (8) except for one minor difference. The entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the tabulation of Gurvich et al. (8) is based on 1 atm. The estimated uncertainty is due to uncertainties in the relative ionic mass and the fundamental constants which are based on the 1981 scale (9) and the 1973 values (7), respectively.

Enthalpy of Formation

The selected value, $\Delta_f H°(0\ K) = -41.258\ kJ\ mol^{-1}$, is obtained from an analysis of spectroscopic data. The adopted values of the ground state vibrational constants, ω_e and $\omega_e x_e$, give $D_0^0 = 2.90$ eV for CaBr(g) by a linear Birge-Sponer extrapolation. Based on the ionicity correction suggested by Hildenbrand (1), this value adjusts to 3.50 eV (337.696 kJ mol^{-1}) which is adopted. The adopted value for D_0^0 gives $D_0^0(CaBr)/\Delta_{at}H°(CaBr_2) = 0.43$ which is quite consistent with values of this ratio for other alkaline earth halide systems (2). Also, Hildenbrand (3, 4) found that the ionicity parameter brings thermochemical and spectroscopic dissociation energies for CaF(g) and CaCl(g) into reasonable agreement. $\Delta_f H°(298.15\ K)$ corresponds to $-49.4\ kJ\ mol^{-1}$.

Ionic model calculations have led to D_0^0 values of 5.29 eV (5) and 3.4 eV (6). The latter result is believed to represent a minimum value for D_0^0. Two other experimental values, which bracket the selected value, have also been reported. Flame studies (7) gave $D_0^0 = 3.29$ eV and chemiluminescence (8) from reaction of Ca atoms with Br gave a lower limit to D_0^0 of 4.22 eV. We assign an uncertainty of $\pm 41.8\ kJ\ mol^{-1}$ to $\Delta_f H°(0\ K)$ to include the possibility that these studies are correct.

Heat Capacity and Entropy

The value of r_e is obtained from that for gaseous $CaBr_2$ (9) with $r_e(CaBr)/r_e(CaBr_2) = 0.96$. The value of this ratio is calculated from bond lengths (2) for several other alkaline earth halide systems. Our adopted value for r_e is supported by an estimate ($r_e = 2.6$ Å) of Krasnov and Karaseva (6) while another etimated value (5) is only 0.14 Å larger than ours. The rotational constant is calculated from the estimated value of r_e. The value of α_e is obtained from a Morse potential function.

The vibrational constants are those recently determined from a complete vibrational analysis of the $D\ ^2\Sigma - X\ ^2\Sigma$ system by Shah (10). These two values are corrected for the natural isotopic abundances of Br. The electronic levels with the exception of those for the D, F, G, and H states are from the compilation of Rosen (11). The D state energy is from Shah (10). The two doublet states (F and G) are estimated by analogy with those for SrBr (9). Recently, Reddy et al. (12) reported observing a new system of bands in the visible emission spectrum of CaBr which was associated with $^2\Sigma - A\ ^2\Pi$ transition. The upper state of this system is assigned the $H\ ^2\Sigma$ state by analogy with SrBr.

		Average	0.406

Heat Capacity and Entropy

All spectroscopic and molecular constants were obtained from Evans et al. (5) except r_e which was calculated from B_e. The value of r_e was reported to be 2.13 Å and 2.11 Å by Beeson and Yost (3) and Cole and Elverum (6), respectively. Ground state configuration was taken from Herzberg (7).

$\Delta_f H°(0\ K) = -50.815 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -58.463 \pm 1.7\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	$\varepsilon_{e,i}$ cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 673\ cm^{-1}$ $\omega_e x_e = 4\ cm^{-1}$ $\sigma = 1$

$B_e = 0.356319\ cm^{-1}$ $\alpha_e = 0.005206\ cm^{-1}$ $r_e = 1.7555\ Å$

Enthalpy of Formation

The equilibrium constant for the reaction $Br_2(g) + BrF_3(g) = 3BrF(g)$ has been measured over the temperature range 328-380 K by Steunenberg et al. (1). 3rd law analysis of the data yields a $\Delta_r H°(298.15\ K) = 11.785 \pm 0.2\ kcal\ mol^{-1}$, with a drift of $-0.6 \pm 1.2\ cal\ K^{-1}\ mol^{-1}$. 2nd law analysis yields $\Delta_r H°(298.15\ K) = 11.98 \pm 0.45\ kcal\ mol^{-1}$, thus it is obvious that the data is thermodynamically self consistent. There is an uncertainty in the entropy of $BrF_3(g)$ of ±1 cal $K^{-1}\ mol^{-1}$ but this corresponds only to ±0.35 kcal mol^{-1} in $\Delta_r H°(298.15\ K)$, thus a best value of $\Delta_r H°(298.15\ K) = 11.78 \pm 0.5\ kcal\ mol^{-1}$ is adopted. This yields $\Delta_f H°(BrF, g, 298.15\ K) = -13.973 \pm 0.4\ kcal\ mol^{-1}$ ($-58.463 \pm 1.7\ kJ\ mol^{-1}$), the uncertainty in the enthalpy of formation being a maximum value comprising the sum of the uncertainties in Br_2, BrF_3 and $\Delta_r H°$.

Attempts have been made to analyze the spectra of BrF to obtain a dissociation energy. Brodersen and Sicre (2), obtained two dissociation limits for BrF of 65.62 kcal mol^{-1} and 54.98 kcal mol^{-1}. The difference corresponds to the $Br(^2P_{1/2}) - Br(^2P_{3/2})$ excitation energy, indicating that the upper state goes to $F(^2P_{3/2})$ and $Br(^2P_{1/2})$. This yields an enthalpy of formation of BrF of $-10.23\ kcal\ mol^{-1}$. Since this value is well outside the possible uncertainty limits of the equilibrium data we must conclude that the extrapolation is in error. Evans et al. (3) have also analyzed the spectra and conclude that an enthalpy of formation of $-14.4\ kcal\ mol^{-1}$ is possible. However, Evans (4) now believes that the dissociating state was too strongly perturbed for meaningful extrapolation.

Heat Capacity and Entropy

All molecular constants were obtained from Evans et al. (3), except r_e and the ground state configuration which were taken from Herzberg (5).

Enthalpy for Formation

$\Delta_f H°(298.15\ K) = -255.588 \pm 2.9\ kJ\ mol^{-1}$ is from Stein (1) and was derived from enthaply of reaction of F_2 with Br_2 which were measured in an adiabatic calorimeter. Stein's value for the $\Delta_f H°(298.15\ K) = -271.040\ kJ\ mol^{-1}$ was based upon gaseous Br_2, which has been adjusted to the liquid Br_2 reference state at 298.15 K.

Heat Capacity and Entropy

Magnuson (2) determined the moments of inertia and quadrupole coupling coefficients of both $^{79}BrF_3$ and $^{81}BrF_3$ from a number of microwave transitions. From the moment of inertia the bromine trifluoride molecule was found to have a distorted "T" structure with one short, 1.721 Å, and two long, 1.810 Å Br-F bonds. The FBrF angle was found to be 86° 12.6'.

Claasen et al. (3), observed two of the six vibrational levels in the vapor, and calculated the other four levels from a normal coordinate treatment of the molecule. They also obtained a measured entropy of $BrF_3(g)$, from low temperature data combined with vapor pressure data and an approximate correction for dimerization. This value is 300.9 $J\ K^{-1}\ mol^{-1}$ at 316.27 K compared with a value of 296.42 $J\ K^{-1}\ mol^{-1}$ from this table, the difference is probably within the uncertainty of the data. The principal moments of inertia are: $I_A = 7.7525 \times 10^{-39}$, $I_B = 20.4920 \times 10^{-39}$ and $I_C = 28.2445 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: 1 $\sigma = 4$

Point Group: C_{4v}

Bond Distances: Br-F = 1.79 Å Br-F* = 1.68 Å

Bond Angles: F-Br-F = [90]° and F*-Br-F = [90]°

(* axial)

Product of the Moments of Inertia: $I_A I_B I_C = 3.20483 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K) = -428.718 \pm 2.1\ kJ\ mol^{-1}$ is from Stein (1) and was derived from enthalpies of reaction of F_2 with Br_2 which were measured in an adiabatic calorimeter. Stein's value for the $\Delta_f H°(298.15\ K) = -444.17\ kJ\ mol^{-1}$ was based upon gaseous Br_2 which has been adjusted to the liquid Br_2 reference state at 298.15 K.

Heat Capacity and Entropy

Begun et al. (2) report the infrared (gas phase) and Raman (liquid phase) spectra and correlate the observations by means of normal coordinate calculations for the similar molecules BrF_5, IF_5, ClF_5 and $XeOF_4$. The fundamental frequencies are taken from Begun et al. (2) except for ν_9 which was beyond the range of their infrared measurements. The value $\nu_9 = 245\ cm^{-1}$ for the gas has been observed by McDowell and Asprey (3) and is confirmed by 237 cm^{-1} found in the Raman spectra of the liquid. Raman values from the liquid were used for the infrared inactive fundamentals ν_4 and ν_6. One Raman active frequency, persumably ν_5, is not observed in any of the four molecules. The value $\nu_5 = 281\ cm^{-1}$ was obtained from the normal coordinate calculation. Previous Raman studies were reported by Stephenson and Jones (4).

A tetragonal pyramidal structure (C_{4v} symmetry) with the above parameters was used by Begun et al. (2) in the analysis of the spectra. This symmetry is consistent with the NMR spectra of Gutowsky and Hoffman (5), with the dipole moment determined by Rogers et al. (6), and with the X-ray crystal structure obtained by Robinson and Bensey (7). Bond distances were based on those in the crystal and the bond angle was assumed to be 90°, slightly larger than those in the crystal (80.5-86.5°). Begun et al. (2) indicate that the angle in the gaseous molecule is probably not exactly 90° but that the normal coordinate calculations are not sensitive to this angle. The three principal moments of inertia are: $I_A = 40.4333 \times 10^{-39}$ and $I_B = I_C = 28.1536 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

$\Delta_f H°(BrSF_5, g, 0\ K) = -953.529 \pm 59\ kJ\ mol^{-1}$ is calculated from a S-Br bond energy of 173.0±42 kJ mol^{-1} by combining D_0^0 with JANAF enthalpies of formation (1) for SF_5 and Br. We estimate the strength of the S-Br bond in $BrSF_5$ from bond energy correlations. In the case of related sulfur chlorine molecules, we calculate that the ratio of the S-Cl bond strength in $ClSF_5$ (1) is 1.1 times the mean S-Cl bond energy in $SOCl_2$ (2). Assuming that this relationship holds for $BrSF_5$ and $SOBr_2$, we obtain the adopted value for $D_0^0(SF_5\text{-}Br)$ from $D_0^0(SOBr\text{-}Br)$, 157.3 kJ mol^{-1}.

The enthalpy of atomization and mean S-F bond energy are calculated to be 1730.5±67 kJ mol^{-1} and 311.3 kJ mol^{-1}, respectively. The latter value is identical with that found for $ClSF_5$, indicating that the sulfur fluorine bonding is very similar in these two molecules. This conclusion is supported by spectroscopic data (1, 3, 4).

Heat Capacity and Entropy

Microwave (3) and vibrational spectroscopic (4) measurements indicate that $BrSF_5$ is a symmetrical top molecule possessing C_{4v} symmetry. We adopt the structural parameters proposed by Neuvar and Jache (3) from an analysis of the observed rotational spectrum. The adopted bond lengths were calculated assuming that the Br-S-F* bond angle was 92° which was estimated from the value (91.6°) for the Cl-S-F* angle in $ClSF_5$ reported by Kewley et al. (5). A more plausible value for the Cl-S-F* angle is 90.7±0.2 (1), indicating that the bond lengths reported by Neuvar and Jache (3) may be slightly biased. We place the values of S°(298.15 K) and $I_A I_B I_C$ in brackets to emphasize this uncertainty.

The vibrational frequencies are based on the infrared and laser-excited Raman spectra of $BrSF_5$ recorded under matrix (argon) isolation conditions by Smardzewski et al. (4). We adjust their reported frequencies for a matrix effect which is estimated as 5 cm^{-1} from gas phase (1) and argon-matrix (4) spectral data for $ClSF_5$. Evidence available for ClS_5 (1) indicates that ν_6 = 220 cm^{-1} by Smardzewski et al. (4) should be reassigned. We believe that this Raman band is the low frequency mode ν_{11} (S-Br wag) and that $\nu 6$ has not been resolved. We estimate ν_6 = 325 cm^{-1} from the force-field value for $ClSF_5$(1).

The principal moments of inertia are: $I_A = 32.1450 \times 10^{-39}$ g cm^2 and $I_B = I_C = 71.9835 \times 10^{-39}$ g cm^2.

Enthaply of Formation

For HBr(g), CODATA (1) recommended the key value $\Delta_f H°(298.15\ K) = -36.38 \pm 0.17\ kJ\ mol^{-1}$ which is adopted. References 2-9 were cited by CODATA.

Heat Capacity and Entropy

The values of ω_e, $\omega_e x_e$, B_e, and α_e are taken from Rank et al. (10) after correction to the averge isotopic species. See also James and Thibault (11), Jones and Gordy (12), Plyler (13), and Mould et al. (14). The ground state configuration is from Huber and Herzberg (15) where molecular constants for HBr(g) are also given.

Our evaluations lead to $S°(298.15\ K) = 198.589\ J\ K^{-1}\ mol^{-1}$ in agreement with the CODATA recommended value (1) of 198.585 ± 0.033 $J\ K^{-1}\ mol^{-1}$, both values based on a reference pressure of one atm. The value adopted, $S°(298.15\ K) = 198.694 \pm 0.033\ J\ K^{-1}\ mol^{-1}$, is the CODATA value corrected, by 0.109 $J\ K^{-1} mol^{-1}$, to a reference pressure of one bar.

930.3(1)	946.3(2)
430.6(1)	632.6(2)

Ground State Quantum Weight: [1] $\sigma = 3$

Point Group: C_{3v}

Bond Distances: Si-H = 1.486 ± 0.008 Å Si-Br = 2.210 Å

Bond Angles: H-Si-H = 110.42° ± 0.5° H-Si-Br = 108.5° ± 0.5°

Product of the Moments of Inertia: $I_A I_B I_C = 3.79963 \times 10^{-115}\ g^3\ cm^6$

Enthalpy for Formation

$\Delta_f H°(298.15\ K)$ is estimated by linear interpolation between the values (1) of $SiBr_4(g)$ and $SiH_4(g)$. The only experimental value for $SiHBr_3(g)$ appears to be too uncertain to justify a nonlinear interpolation such as that adopted for SiH_3Cl (1). Normally we would seek a comparison with $\Delta_f H°$ values of CH_nBr_{4-n}. These were recently reviewed by Kudchadker and Kudchadker (2). They adopted a cubic variation of $\Delta_f H°$ with n, based on $\Delta_f H°$ values of $CHBr_3$ and CBr_4 selected by Wagman et al. (3). We presume that Wagman's values are calculated rather than experimental. Uncertainty in these values (4-6) precludes their use as a comparison for SiH_nBr_{4-n}. We conclude, as did Hunt and Sirtl (15), that the available data justify only linear interpolation of $\Delta_f H°$.

Heat Capacity and Entropy

The molecular structure is based on microwave data of Kewley et al. (7) for isotopic forms of the four monohalosilanes. The authors concluded that the silyl group is effectively the same in all four halides. We adopt effective (r_o) structural parameters rather than substitutional (r_s) parameters. These are in reasonable agreement with previous structural determinations (8). The principal moments of inertia are $I_A = 0.9971 \times 10^{-39}$ and $I_B = I_C = 19.5210 \times 10^{-39}\ g\ cm^2$.

Vibrational frequencies are from gas-phase infrared spectra (9) measured with a grating spectrometer by Buerger et al. Assignments were based on analysis of band contours and rotational fine structure. These results supersede Shimanouchi's selected frequencies (10) which derive from lower resolution spectra. The new data agree with unpublished data cited by Ball et al. (11).

We neglect excited states and assume the electronic ground state to be $^1A_1$ by analogy with CH_3Br (12). SiH_3Br has several high-lying electronic absorptions and a diffuse band with a maximum at ~52000 cm^{-1} (13). Comparison (12, 13) with CH_3Br (12,14) suggests that the lowest excited state in SiH_3Br is near 40000 cm^{-1}. Contributions due to excited states should be unimportant.

PREVIOUS. December 1976 (1 atm) CURRENT: December 1976 (1 bar)

AMMONIUM BROMIDE (NH_4Br) CRYSTAL M_r = 97.94246

$S°(298.15\ K) = 112.84\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 411\ K$
$T_{fus} = 815.2\ K$

$\Delta_f H°(0\ K) = -255.0 \pm 1.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -271.5 \pm 1.3\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 3.222\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The equilibrium pressures for the reaction $NH_4Br(cr) + NH_3(g) + HBr(g)$ have been measured by several investigators. Using the densi-tensimeter, Smits and Purcell (2), determined both the equilibrium pressures and vapor densities of the decomposition products, simultaneously, at several temperatures. In order to check the density values obtained, the authors applied the "extrapolation method", from which it was calculated that the corresponding vapor density agreed with complete dissociation. Based on this conclusion, the reported equilibrium pressures were employed to evaluate the enthalpy changes ($\Delta_r H°$) of the decomposition reaction by both the 2nd and 3rd law methods. The results obtained are presented as follows.

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Equipment Used
Smith and Calvert (1)	576.40-676.02	45.12±0.13	44.93	Isoteniscope
Smits and Purcell (2)	604.95-668.15	45.50±0.17	45.08	Densi-tensimeter
Johnson (3)	573.15-667.75	45.41±0.44	44.85	Spiral Manometer

The value of $\Delta_r H°(298.15\ K)$ adopted is 45.2±0.2 kcal mol^{-1}. Using $\Delta_f H°(298.15\ K)$ = -10.97 and -8.71 kcal mol^{-1} for $NH_3(g)$ and HBr(g), respectively, the value of $\Delta_f H°(298.15\ K)$ for $NH_4Br(cr)$ is evaluated as -64.9±0.3 kcal mol^{-1} (-271.542±1.3 kJ mol^{-1}). The corresponding $\Delta_r H°(298.15\ K)$ value evaluated from solution data, selected by Parker (4) is 45.5±0.2 kcal mol^{-1}.

The vapor densities (573-661 K) of dissociation products of $NH_4Br(cr)$ were also measured by Smith and Lombard (5). Using the equilibrium pressures reported by Smith and Calvert (1), they derived the corresponding degrees of dissociation of $NH_4Br(cr)$ at different temperatures. The calculated results indicated that only 48% of $NH_4Br(cr)$ decomposed at 573 K and as reaction temperatures increased to 661 K the degree of dissocation decreased to 10%. This conclusion was stated to be erroneous by Smits and Purcell (2) probably because of incorrect density determinations.

Heat Capacity and Entropy

The low temperature (13-305 K) heat capacities and S°(298.15 K) were obtained from Sorai et al. (6). The $C_p°$ values above 305 K were estimated by comparison with those for NaCl(cr), NaBr(cr) and $NH_4Cl(cr)$. The low temperature heat capacities were also measured by Ewald (7), 139-301 K, and by Simon et al. (8), 201.2-277.1 K.

Transition Data

The temperature (T_{trs}) and enthalpy of transition ($\Delta_{trs} H°$) were given by Bridgman (9). T_{trs} = 419.5±0.6 K was reported Markowitz and Boryta (10), which was determined by differential thermal analysis. According to Sorai et al. (6), there are three solid phase transitions, namely Phase IV (CsCl) → Phase III (tetragonal) at 108 K, Phase III (tetragonal) → Phase II (CsCl) at 235 K and Phase II (CsCl) → Phase I (NaCl) at 411 K.

Fusion Data

The value of T_{fus} was taken from Rassow (11), determined under pressure.

Decomposition Data

The temperature of decomposition was calculated as 670 K, i.e. the temperature at which the total pressure of the decomposition products for the reaction $NH_4Br(cr) \rightarrow NH_3(g) + HBr(g)$ equals 1 atm. Values of 674 and 668.4 K were reported by Luft (12) and Markowitz and Boryta (10), respectively.

Enthalpy of Formation

Gaydon (1) gives 0.7±0.4 eV for the dissociation energy into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from Wieland (2) were weighted according to their natural isotopic abundances. The bond length was estimated to be 0.965 of the mercuric bond length by analogy with the mercury chlorides. Rotational constants were estimated (3).

Enthalpy for Formation

The equilibrium constants for the reaction (A) $I_2(g) + Br_2(g) = 2\ IBr(g)$ were determined to be 0.01124 and 0.01303 at 547.7 and 578 K, respectively, by Muller (1) who studied the rate of reaction between $H_2(g)$ and $Br_2(g)$ in the presence of $I_2(g)$. Bodenstein and Schmidt (2) derived two values of the equilibrium constants at 1495 K for the same reaction by vapor density studies on the system I_2, I, Br_2, Br and BrI. The equilibrium between $CuBr_2(cr)$, $I_2(g)$, CuBr(cr) and IBr(g) was investigated by McMorris and Yost (3) and the equilibrium constants at 115.0, 151.2 and 176.0°C for reaction (A) were evaluated. Based on these reported equilibrium constants, the corresponding enthalpy changes for reaction (A) are calculated by both the 2nd and 3rd law methods.

Badger and Yost (4) observed the infrared bands of IBr and classified them as the $A^3\Pi_2$-$X'\Sigma$ transition. They have shown that the dissociation products of the upper state are normal atoms. Brown (5) assigned a faint set of bands in the red as the $B^3\Pi_0$ + $X'\Sigma$ system. By means of a vibrational analysis he found that the absorption spectrum of IBr is analogous to that of ICl. The dissociation energy for IBr was evaluated to be 14,660±5 cm^{-1} or 1.817 eV. Hence the enthalpy change for the reaction (B) IBr(g) = I(g) + Br(g) is calculated as 41.92 kcal mol^{-1}.

The enthaplies of formation for IBr(g) derived from the enthalpy changes for reaction (A) and (B) are presented in the following table. The value of $\Delta_f H°$(IBr, g, 298.15 K) adopted is 9.77±0.02 kcal mol^{-1} (40.878±0.08 kJ mol^{-1}).

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Muller (1)	A	547.7, 578	2	-3.07	-3.38	-0.55	9.47
Bodenstein and Schmidt (2)	A	1495	1	-	-2.92	-	9.70
McMorris and Yost (3)	A	388.2-449.2	14	-2.46	-2.85	-0.9±0.4	9.73
Brown (5)	B	298	-	-	41.92**	-	9.77**

**The value is derived from D_0^0(I-Br).

Heat Capacity and Entropy

The ground state configuration, electronic levels, quantum weights, ω_e and $\omega_e x_e$ are obtained from Herzberg (6). The values of B_e, α_e(corrected to the average isotopic species) and r_e were reported by Jaseja (7) who analyzed the microwave spectrum of IBr, *corresponding to the transitions J = 4 ← 5 and J = 5 ← 6*, for the two isotopic species, $^{127}I^{79}Br$ and $^{127}I\ ^{81}Br$.

The infrared absorption spectrum of IBr at 8000 - 6800 Å, associated with a $^3\Pi_1 \leftarrow X^1\Sigma^+$ transition, was observed by Selin (8). The derived rotational constants are different from those reported by Jaseja (7).

PREVIOUS: December 1966 (1 atm) CURRENT: December 1966 (1 bar)

$S°(298.15\ K) = 95.94 \pm 0.04\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1007\ K$

$\Delta_f H°(0\ K) = -386.674 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -393.798 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 25.5\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of solution, $\Delta_{sol}H$, of KBr(cr) in $H_2O(\ell)$ has been measured by many investigators. The results were reviewed in detail by Parker (1). Eight pertinent $\Delta_{sol}H°(aq, \infty)$ values are reproduced in the table below. Adopting the best value, $\Delta_r H°(298.15\ K) = 4.75 \pm 0.02\ kcal\ mol^{-1}$, for the reaction $KBr(cr) = K^+(aq, \infty) + Br^-(aq, \infty)$, we derive $\Delta_f H°(298.15\ K) = -94.12\ kcal\ mol^{-1}$ for KBr(cr) ($-393.798\ kJ\ mol^{-1}$). The auxiliary values $\Delta_f H°(298.15\ K) = -60.32$ and $-29.05\ kcal\ mol^{-1}$ for $K^+(aq, \infty)$ and $Br^-(\infty H_2O)$, respectively, are obtained from reference (2).

*Values are adjusted to 298.15 K and to infinite dilution.

**Lowest experimental molality.

Heat Capacity and Entropy

The low temperature heat capacities, 2.9 - 272.2 K, were measured by Berg and Morrison (11) using an adiabatic calorimeter. The high temperature heat capacities, 325.25 - 711.75 K, are taken from Mustajoki (12). These two sets of $C_p°$ data are joined smoothly at 298.15 K. The $C_p°$ values at temperatures, 720 - 1007 K, are extrapolated graphically, so that the derived enthalpy change $H°(1007\ K)-H°(298.15\ K) = 9.9\ kcal\ mol^{-1}$ agrees with that determined by Dworkin (13). The derived enthalpies at 700, 800 and 900 K are also in good agreement with those measured by Skuratov and Lapushkin (14). The $C_p°$ values above 1007 K are obtained by graphical extrapolation.

The $S°(298.15\ K)$ is calculated from the adopted low temperature $C_p°$, based on $S°(2.9\ K) = 0.006276\ J\ K^{-1}\ mol^{-1}$.

The heat capacities of KBr(cr) were also measured by Nernst and Lindemann (15), 78.7 - 89.2 K; Koref (16), 137 - 234 K; and Clusius et al. (17). The enthalpies of KBr(cr) were determined by Magnus (18) and by Cooper (19). The results are in reasonable agreement with the adopted functions except for those reported by Cooper (14).

Fusion Data

See the liquid table for details.

Sublimation Data

The heats of sublimation to monomer and dimer are calculated as the enthalpy changes for the following two reactions: $KBr(cr) = KBr(g)$ and $2\ KBr(cr) = K_2Br_2(g)$.

PREVIOUS: December 1961 CURRENT: March 1967

$S°(298.15\ K) = [105.540]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1007\ K$

$\Delta_f H°(298.15\ K) = [-376.492]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 25.522\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(1007 K)-H°(298.15 K), between the crystal and liquid.

Toguri et al. (1) studied the chemical equilibrium for the reaction KBr(ℓ) + HCl(g) = KCl(ℓ) + HBr(g). They obtained $\Delta_r G°(1073\ K) = 3.50 \pm 0.08$ and 3.54 kcal mol^{-1} from partial pressure data and emf data, respectively. The corresponding value calculated from these tables is 3.78 kcal mol^{-1}. Combination of the experimental results with JANAF auxiliary data leads to -89.70 and -89.74 kcal mol^{-1} for $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

The heat capacity of 16.7 cal K^{-1} mol^{-1} (69.873 J K^{-1} mol^{-1}) was derived by Dworkin (2) from enthalpy data in the range 1010 -1100 K. This $C_p°$ value is adopted here for the temperature range 298 - 2500 K.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The adopted T_{fus} = 1007 K and $\Delta_{fus} H°$ = 6.1 kcal mol^{-1} (25.522 kJ mol^{-1}) were determined by Johnson and Bredig (3) and Dworkin and Bredig (4), respectively.

Enthalpies of melting of 6.2 kcal mol^{-1} from phase diagram studies and 6.7 kcal mol^{-1} from calorimetric measurements were obtained by Aukrust et al. (5).

Vaporization Data

The boiling point, T_{vap} = 1671 K, is calculated as the temperature at which the sum of the partial pressures of KBr(g) and K_2Br_2(g) over KBr(ℓ) equals one atmosphere. The value of $\Delta_{vap} H°$ is calculated as the enthalpy required to produce one mole of vapor mixture, which contains 19.5% dimer (K_2Br_2) and 80.5% monomer (KBr).

T_{vap} was reported to be 1648 and 1668 K by von Wartenberg and Albrecht (6) and Ruff and Mugdan (7), respectively.

$B_e = 0.0807\ cm^{-1}$ $\alpha_e = 0.000401\ cm^{-1}$ $r_e = 2.821$ Å

Enthalpy of Formation

The enthalpy of formation is derived from the sublimation and vaporization data analyzed below. Numerous investigators have obtained total pressures by static methods or "apparent" pressures by effusion or transpiration. These pressures are converted to monomer pressures by use of functions [see $K_2Br_2(g)$ table] which are consistent with the dimer-monomer equilibrium data of Hagemark et al. (6). 2nd and 3rd law analyses of the monomer pressures show remarkable consistency over temperatures from 637 to 1668 K. The selected value of $\Delta_f H°(298\ K) = -43.04 \pm 0.5\ kcal\ mol^{-1}$ ($-180.079 \pm 2.1\ kJ\ mol^{-1}$) may be compared with $-43.8\ kcal\ mol^{-1}$ derived from $D_0^0 = 3.95$ eV which is reported by Gaydon (1)] based on atomic fluorescence data.

Reactions: (A) KBr(ℓ) = KBr(g) (B) KBr(cr) = KBr(g)

Heat Capacity and Entropy

Rusk and Gordy (10) have investigated the pure rotational spectra of KBr in the 1.5 to 5.0 mm range of the microwave region by millimeter wave molecular beam spectroscopy. The reported values of ω_e, $\omega_e x_e$, B_e and r_e are adopted here and corrected to the average isotopic species. The value of α_e is obtained from Fabricand et al. (11). Molecular constants for KBr(g) have also been reported by Hertzberg (12) and Rice and Klemperer (13). They are in good agreement with the values adopted. Herzberg (12) also lists an A state in 31770 cm^{-1} based on observed electronic spectra.

PREVIOUS: March 1967 (1 atm) CURRENT: March 1967 (1 bar)

$S°(298.15\ K) = [74.06]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 823\ K$

$\Delta_f H°(0\ K)$ = unknown

$\Delta_f H°(298.15\ K) = -350.9 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.656\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(LiBr, cr, 298.15\ K) = -83.87\ kcal\ mol^{-1}(-350.912\ kJ\ mol^{-1})$ was calculated from the enthalpy of solution of lithium bromide (cr) at infinite dilution and the ionic enthalpies of formation of $Li^+(aq,\infty)$ and $Br^-(aq,\infty)$.

Parker (1) reviewed the enthalpy of solution data in the literature and gave the "best" value, $\Delta_{sol}H^\infty = -11{,}670 \pm 50$ cal mol^{-1} for LiBr(cr) + LiBr(aq,∞) at 298.15 K. The ionic enthalpy of formation, $\Delta_f H°(Li^+, aq,\infty\ 298.15\ K) = -66.49\ kcal\ mol^{-1}$, was calculated from $\Delta_f H°(LiOH, aq,\infty\ 298.15\ K) = -121.46\ kcal\ mol^{-1}$ (2) with $\Delta_f H°(OH^-, aq,\infty\ 298.15\ K) = -54.97\ kcal\ mol^{-1}$ (3). The $v\Delta_f H°(Br^-, aq,\infty, 298.15\ K) = -29.05\ kcal\ mol^{-1}$ was also obtained from (3). Combination of the ionic enthalpies of formation of $Li^+(aq,\infty)$ and $Br^-(aq,\infty)$ gives the enthalpy of formation of LiBr(aq,∞), $\Delta_f H°(298.15\ K) = -95.54\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

Dworkin (4) has measured the enthalpy changes by the drop method (723-883 K), yielding $H°(823;298) = 7.0\ kcal\ mol^{-1}$ for the crystal at the melting point. Heat capacities derived from his data were $C_p°(773\ K) = 15.1$ and $C_p°(853\ K) = 15.6\ cal\ K^{-1}\ mol^{-1}$ for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of LiCl(cr), NaCl(cr) and NaBr(cr).

$S°(298.15\ K) = 17.7\ cal\ K^{-1}\ mol^{-1}(74.06\ J\ K^{-1}\ mol^{-1})$ was estimated by adding the entropy difference between NaBr(cr) and NaCl(cr) to the entropy of lithium chloride (cr) at 298.15 K. Comparisons with other alkali halides give results within ±0.5 cal $K^{-1}\ mol^{-1}$ of this value. Kelley (5) has estimated $C_p° = 11.50 + 3.02 \times 10^{-3}T\ cal\ K^{-1}\ mol^{-1}$ and $S°(298.15\ K) = 16.0 \pm 0.5\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

The selected enthalpy of fusion, $\Delta_{fus}H°(823\ K) = 4.22\ kcal\ mol^{-1}(17.656\ kJ\ mol^{-1})$, was obtained from enthalpy measurements in a drop calorimeter by Dworkin and Bredig (6).

Kelley (7) reviewed some phase diagram studies of the lithium bromide system in the literature, and gave the enthalpy of fusion $\Delta_{fus}H°(825\ K) = 2.90\ kcal\ mol^{-1}$. Blanc (8) reported the enthalpy of fusion $\Delta_{fus}H°(819\ K) = 3.095\ kcal\ mol^{-1}$ by a cryoscopic method. Both values are too low.

PREVIOUS: September 1961 CURRENT: June 1966

$S°(298.15\ K) = [84.603]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 823\ K$

$\Delta_f H°(298.15\ K) = [-338.226]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.656\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding the $\Delta_{fus}H°$ and the difference in enthalpy, H°(823 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Dworkin (1) has derived the heat capacity Cp = 15.6 cal K^{-1} mol^{-1} from enthalpy measurements (823 - 883 K) by the drop method. The liquid heat capacity was assumed to be constant as 15.6 cal K^{-1} mol^{-1}. S°(298.15 K) is obtained in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap}(ℓ→monomer) is taken as the temperature at which the calculated Gibbs energy change is zero for LiBr(ℓ) → LiBr(g), while $\Delta_{vap}H°$(ℓ→monomer) is the corresponding enthalpy of vaporization.

T_{vap}(ℓ→equilibrium mixture) is taken as the temperature at which the sum of the calculated partial vapor pressures of LiBr(g) and Li_2Br_2(g) reaches one bar (trimer and higher polymers have been neglected in calculation). This value (1562 K) is in good agreement with the boiling point (at 1 atm) of 1583 K obtained from total vapor pressure measurements by von Wartenberg and Schulz (2) and also the boiling point of 1538 K by Ruff and Mugdan (3). $\Delta_{vap}H°$(ℓ→equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 29.23 mole percent of dimer. For detailed information see LiBr(g) and Li_2Br_2(g) tables.

Lithium Bromide (LiBr) Br_1Li_1(cr,l)

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

LITHIUM BROMIDE (LiBr) IDEAL GAS M_r = 86.845

$S°(298.15\ K) = 224.345\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -146.3 \pm 13\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -154.0 \pm 13\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State $^1\Sigma$	ε_i, cm^{-1}	g_i
	0	1

$\omega_e = 563.16\ cm^{-1}$ $\omega_e x_e = 3.53\ cm^{-1}$ $\sigma = 1$

$B_e = 0.56112\ cm^{-1}$ $\alpha_e = 0.00573\ cm^{-1}$ $r_e = 2.1704$ Å

Enthalpy of Formation

$\Delta_f H°$(LiBr, g, 298.15 K) = -36.8±3 kcal mol^{-1} (-153.971±13 kJ mol^{-1}) is calculated from the selected enthalpy of vaporization and the enthalpy of formation for lithium bromide (ℓ). Lithium bromide vaporizes to a mixture of monomeric and dimeric gases. (Higher polymers have been neglected in the calculation.) The enthalpies of vaporization to monomer and to dimer were chosen to satisfy (1) the total vapor pressure data measured by von Wartenberg and Schulz (1) and by Ruff and Mugdan (2); the partial vapor pressures of monomer and dimer derived from Miller and Kusch (3) in an analysis of the velocity distribution of molecules in alkali halide vapor. The selected enthalpies of vaporization are $\Delta_{vap}H°$(ℓ→monomer, 298.15 K) = 44.0±3 kcal mol^{-1} and $\Delta_{vap}H°$(ℓ→dimer, 298.15 K) = 42.0±5 kcal mol^{-1} which combine with the enthalpy of formation of lithium bromide (ℓ), $\Delta_f H°$(298.15 K) = -80.84 kcal mol^{-1}, to give the standard enthaply of formation of LiBr(g) and Li_2Br_2(g) -36.8 and -119.7 kcal mol^{-1} (-153.971 and -500.825 kJ mol^{-1}), respectively. The derived enthaply of dissociation is $\Delta_d H°$(298.15 K) = 46.0 kcal mol^{-1} for Li_2Br_2(g) → 2LiBr(g).

Berkowitz et al. (4) have measured mass-spectrometrically the enthaply of dissociation $\Delta_r H°$(850 K) = 45.9 kcal mol^{-1} ($\Delta_r H°$(298.15 K) = 46.9 kcal mol^{-1}) for Li_2Br_2(g) → 2LiBr(g) in a double oven apparatus by the 2nd Law method. Hildenbrand et al. (5) have determined mass-spectrometrically the enthaply of sublimation of lithium bromide by the 2nd Law method as $\Delta_{sub}H°$(cr→monomer, 740 K) = 46.9 and $\Delta_{sub}H°$(cr→dimer, 740 K) = 45.0 kcal mol^{-1} (equivalent to $\Delta_{vap}H°$(ℓ→monomer, 298.15 K) = 45.82 kcal mol^{-1} and $\Delta_{vap}H°$(ℓ→dimer, 298.15 K) = 41.93 kcal mol^{-1}). These values are in reasonable agreement with those selected in the tabulation.

Heat Capacity and Entropy

The bond distance (r_e) was obtained from the microwave studies by Honig et al. (6). The vibrational constants (ω_e and $\omega_e x_e$) were determined from the infrared spectrum by Klemperer et al. (7). The rotational constants which have been corrected to the average isotopic species were obtained by Herbert et al. (8) using microwave spectra. Their data are in good agreement with those reported by Honig et al. (6) and Rusk and Gordy (9).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by Wilkins (10) who used slightly different molecular constants.

Enthaply of Formation

No thermochemical measurement of the enthaply of formation has been made. The selected value, $\Delta_f H°(MgBr, g, 0\ K) = -6.611 \pm 10.0$ kcal mol^{-1} (-27.660 kJ mol^{-1}), is based on an analysis of spectroscopic data. Herzberg (1) obtained the value $D_0^0 < 3.35$ eV from predissociation which sets in above v = 3 of $A^2\Pi$ state. Gaydon (2) recommended $D_0^0 = 3.2 \pm 1.0$ eV which was obtained from a linear Birge-Sponer extrapolation of the ground state vibrational levels (v, 0-6). Our adopted vibrational constants give this same value by a similar extrapolation. The linear Birge-Sponer D_0^0 value adjusts to 3.03 eV (69.79 kcal mol^{-1}) when corrected for the ionic character of the Mg-Br bond by the method suggested by Hildenbrand (3). This adjusted D_0^0 value is adopted and corresponds to $\Delta_f H°(298.15\ K)$ of -35.3 kJ mol^{-1}.

Two lower values of D_0^0 have been reported from results of ionic model calculations (4, 5). Margrave (4) calculated an ionic binding energy of 135 kcal mol^{-1} which gives D_0^0 = 1.75 eV. Krasnov and Karaseva (5), using a Rittner potential function (6), found D_0^0 = 2.39 eV which probably represents a minimum value. In addition, we find $D_0^0(MgBr, g, 298.15\ K)/\Delta_{at}H°(MgBr_2, g, 298.15\ K) = 0.44$ which is quite consistent with values of this ratio for other alkaline-earth halides (7). This consistency provides further support for our adopted results. An estimated uncertainty of ±10.0 kcal mol^{-1} (41.8 kJ mol^{-1}) is believed to be realistic.

Heat Capacity and Entropy

Values for the ground state vibrational constants and bond length are taken from the tabulation of Rosen (8). The adopted value of r_e which was obtained from a rotational analysis of the (0,0) bands of the $A^2\Pi$-$X^2\Sigma$ system by Patel and Patel (9, 10) gives $r_e(MgBr)/r_e(MgBr_2) = 1.01$. Comparison of values for this ratio for several alkaline-earth halides (7) shows that $r_e(MX)/r_e(MX_2)$ is generally slightly less than one (~0.96). This suggests that the uncertainty in $r_e(MgBr)$ may be as high as 0.1 Å, assuming r_e for $MgBr_2$ is correct (7). The value of B_e is calculated from r_e. α_e is obtained from the other constants assuming a Morse potential function.

The electronic levels except for the two uppe most states are from Rosen (8). We estimate a $^2\Sigma$ state to lie at 26500 cm^{-1} by analogy with those observed for CaBr and SrBr (7). The assignment o the level at 39285.9 cm^{-1} is rather uncertain. Rosen (8) has assigned this level as a $C^2\Pi$ state. Very recently, Reddy and Rao (11) observed that the bands were single-headed, and they attributed the system to a $C^2\Sigma$ - $X^2\Sigma$ transition by analogy with that for MgF. Comparison of the observed spectra for MgCl, CaBr, SrBr, and BaBr (7) suggests yet another assignment. It appears likely that the observed level near 40000 cm^{-1} arises from a $D^2\Sigma$-$X\ ^2\Sigma$ transition, and the $C^2\Pi$ state, estimated to lie near 30000 cm^{-1}, has gone unobserved. We tentatively adopt the assignment of Reddy and Rao (11). However, thermodynamic functions based on the alternate assignments are not significantly different from those adopted, below 4500 K.

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K)$ is that estimated by Brewer (1) using bonding models. The value of $\Delta_f H°(0\ K)$ combined with JANAF data (2) for Mo(g) and Br(g) gives D_0^0(Mo-Br) = 310.87±42 kJ mol^{-1}. This value of the bond dissociation energy agrees favorably with the mean Mo-Br bond energy $\Delta_{at}H°(MoBr_4, g, 0\ K)/4$ = 317.98 kJ mol^{-1} (2).

Enthalpy Capacity and Entropy

The Mo-Br bond length of 2.42 Å and the ground state vibrational frequency of 300 cm^{-1} are estimates from Brewer (1). The electronic contributions are assumed to be the same as those of the free gaseous ion, Mo^+, as suggested by Brewer (1). All states up to 17,344 cm^{-1} as listed by Moore (3) are included in the calculation. Our thermodynamic functions differ slightly from those reported by Brewer (1) due to the use of non-zero values for $\omega_e x_e$ and α_e. Estimates for α_e and $\omega_e x_e$ are based on the empirical correlations of Calder and Ruedenberg (4).

PREVIOUS: September 1978 (1 atm) CURRENT: September 1978 (1 bar)

$S°(298.15\ K) = 235.48 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 308.4 \pm 21\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 300.8 \pm 21\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^3\Sigma^-$	0	3

$\omega_e = 699.1\ cm^{-1}$ $\omega_e x_e = 4.7\ cm^{-1}$ $\sigma = 1$

$B_e = 0.443\ cm^{-1}$ $\alpha_e = 0.00399\ cm^{-1}$ $r_e = 1.79$ Å

Enthaply of Formation

Miller and Dunford (1) have extrapolated the ground state vibrational levels and obtain $D_0^0 = 67 \pm 5$ kcal mol^{-1} or $\Delta_f H°(0\ K) = 73.7 \pm 5$ kcal mol^{-1} (308.361 ± 21 kJ mol^{-1}).

Heat Capacity and Entropy

Miller and Dunford (1) give all the vibrational and rotational constants, which have been adjusted to the normally occurring isotopic mixture for bromine.

Enthaply of Formation

The chemical equilibrium of the reaction $2NO(g) + Br_2(g) = 2NOBr(g)$ has been studied by Trautz and Dalal (1), Blair et al. (2), and Krauss (3). Using the reported equilibrium constants, the enthalpy changes $\Delta_r H°(298.15\ K)$, of this reaction are evaluated by both the 2nd and 3rd law methods. Based on the 3rd law $\Delta_r H°(298.15\ K)$ values, the enthaplies of formation for NOBr(g) are derived. The results obtained are presented in the table below. The value of $\Delta_f H°(NOBr, g, 298.15\ K)$ adopted is 19.63±0.2 kcal mol^{-1} (82.132±0.8 kJ mol^{-1}).

Source	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1}mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

*The data points employed for evaluation are calculated from a given equation.

Heat Capacity and Entropy

The molecular structure of NOBr(g) has been determined by electron diffraction by Ketelaar and Palmer (4). The results were confirmed later by Weatherly and Williams (5), who studied the microwave spectrum of NOBr(g) in the region 20000 - 40000 Mc/sec and analyzed the J = 2 → 3 transition. The values of bond length and angle adopted are obtained from Ketelaar and Palmer (4). The infrared absorption spectrum of NOBr(g) has been examined from 400 to 5303 cm^{-1} by Burns and Bernstein (6). The authors observed the first two fundamental vibrational frequencies and obtained the third from combination and overtones. These assignments are adopted. The principal moments of inertia are: $I_A = 0.9405 \times 10^{-39}$, $I_B = 22.9668 \times 10^{-39}$ and $I_C = 23.9093 \times 10^{-39}$ g cm^2.

PREVIOUS: December 1966 (1 atm) CURRENT: December 1966 (1 bar)

$S°(298.15\ K) = 86.82 \pm 0.25\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1020\ K$

$\Delta_f H°(0\ K) = -354.30 \pm 0.42\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -361.41 \pm 0.42\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 26.108\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of solution of NaBr(cr) in water has been measured by Askew et al. (1) and Wallace (2) to be +0.01 and -0.144 kcal mol^{-1}, respectively. Using $\Delta_f H°(Na^+, aq, 298.15\ K) = -57.39$ and $\Delta_f H°(Br^-, aq, 298.15\ K) = -29.05$ kcal mol^{-1}, from Wagman (3)., the respective value of $\Delta_f H°(298.15\ K)$ for NaBr(cr) was found to be -86.3 and -86.45 kcal mol^{-1}. The adopted value is the average of these two.

Heat Capacity and Entropy

The low temperature heat capacities (7.21 - 301.73 K) were measured by Gardner and Taylor (4). The high temperature enthalpy changes (290 - 645, 290 - 816 K) were determined by Magnus (5). Based upon the latter data, the high temperature heat capacities were derived. The two sets of $C_p°$ data were joined smoothly at 298.15 K by graphical method. S°(298.15 K) was obtained from Gardner and Taylor (4) using $S°(10\ K) = 0.034$ cal $K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} and $\Delta_{fus}H°$ were reported by Dworkin and Bredig (6). The values, $T_{fus} = 1014$ K and $\Delta_{fus}H° = 5.52$ kcal mol^{-1}, reported by Blanc (7) were not used.

Sublimation Data

The value of $\Delta_{sub}H°(298.15\ K)$ was derived from six sets of vapor pressure data by both the 2nd and 3rd law methods. See the ideal gas table for details.

$\Delta_{fus} H° = 26.108\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1020\ K)-H°(298.15\ K)$, between the crystal and liquid. The equilibrium constant of the reaction $NaBr(\ell) + HCl(g) = NaCl(\ell) + HBr(g)$ has been determined by Toguri et al. (1). From the reported data, $\ln K(800°C) = -1.19 \pm 0.01$, the enthalpy of reaction ($\Delta_r H°(298.15\ K)$) was derived to be 2.11 kcal mol^{-1}. Using $\Delta_f H°(HCl, g, 298.15\ K) = -22.062$, $\Delta_f H°(NaCl, \ell, 298.15\ K) = -92.24$ and $\Delta_f H°(HBr, g, 298.15\ K) = 8.70$ kcal mol^{-1}, the value of $\Delta_f H°(298.15\ K)$ for $NaBr(\ell)$ was evaluated to be -81.0 ± 0.5 kcal mol^{-1} which is in reasonable agreement with the value adpted. The values of $\Delta_f H°(298.15\ K)$ for $HCl(g)$ and $HBr(g)$ were obtained from Wagman (2).

Heat Capacity and Entropy

Heat capacity for $NaBr(\ell)$ is estimated by comparison with those for $NaCl(cr)$, $NaCl(\ell)$, $AgCl(cr)$, and $AgCl(\ell)$. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} and $\Delta_{fus} H°$ were reported by Dworkin and Bredig (3). The values, $T_{fus} = 1014\ K$ and $\Delta_{fus} H° = 5.52$ kcal mol^{-1}, reported by Blanc (4), were not used.

Vaporization Data

The boiling point, $T_{vap}(\ell \rightarrow monomer)$, is calculated as the temperature at which the value of $\Delta_r G° = 0$ for the reaction $NaBr(\ell) \rightarrow NaBr(g)$. The difference between $\Delta_f H°$ for $NaBr(\ell)$ and $NaBr(g)$ at $T_{vap}(\ell \rightarrow monomer)$ is the enthalpy of vaporization, $\Delta_{vap} H°(\ell \rightarrow monomer)$.

SODIUM BROMIDE (NaBr) IDEAL GAS M_r = 102.89377

$S°(298.15\ K) = 241.218\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -135.04 \pm 2.09\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -143.93 \pm 2.09\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 302.1 \pm 4\ cm^{-1}$ $\omega_e x_e = 1.50\ cm^{-1}$ $\sigma = 1$
$B_e = 0.1495\ cm^{-1}$ $\alpha_e = 0.000939\ cm^{-1}$ $r_e = 2.5020 \pm 0.0001$ Å

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was calculated from $\Delta_f H°(298.15\ K)$ and $\Delta_{sub} H°(298.15\ K)$ for NaBr(cr). The latter was derived by both the 2nd and 3rd law methods from six sets of vapor pressure data, corrected for the presence of dimer species in the vapor. The results are listed as follows.

Source	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	$\Delta_f H°(298.15\ K)$[a] kcal mol^{-1}
Niwa (1)	NaBr(cr) + NaBr(g)	50.31	51.97	-35.24
Cogin and Kimball (2)	NaBr(cr) + NaBr(g)	52.14	52.26	-34.18
Mayer and Wintner (3)	NaBr(cr) + NaBr(g)	65.30	52.59	-33.79b
Ruff and Mugdan (4)	NaBr(l) + NaBr(g)	47.48	46.43	-34.15
Wartenberg and Albrecht (5)	NaBr(l) + NaBr(g)	47.54	46.38	-34.15
Bloom et al. (6)	NaBr(l) + NaBr(g)	51.53	46.23	-34.88b

a Based on the average of the 2nd and 3rd law values.
b Only the 3rd law value being used.

The value of $\Delta_f H°(NaBr, g, 298.15\ K) = -34.40 \pm 0.50$ kcal mol^{-1} (-143.930 kJ mol^{-1}) adopted is the average value of the six $\Delta_f H°(298.15\ K)$ values listed in the above table. The dissociation energy was calculated to be 86.28 kcal mol^{-1} or 3.74 eV which is in good agreement with the values, 3.84 ± 1 and 3.85 eV, reported by Gaydon (7) and Herzberg (8), respectively. According to Brewer (9), Gaydon's original reported value, $D_0^0 = 3.8$, is an average of the value of 3.84 eV from atomic fluorescence and the value of 3.75 eV calculated for Gaydon by Brewer from pressure data available at that time.

Heat Capacity and Entropy

The values of ω_e, $\omega_e x_e$, B_e and α_e were taken from Rice and Klemperer (10). The adopted bond distance (r_e) reported by Honing et al. (11) was derived from microwave spectrum. By electron-diffraction method, the Na-Br bond distance was determined as 2.64 ± 0.01 Å by Maxwell et al. (12). The discrepancy may be due to the presence of a large proportion of dimer at the higher pressures used in the electron-diffraction determination. The ground state configuration was reported by G. Herzberg (8).

PHOSPHORUS BROMIDE (PBr) IDEAL GAS M_r = 110.87776

$S°(298.15\ K)$ = [249.2] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [170.7] kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [162.6] kJ mol^{-1}

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^3\Sigma$	0	[3]

ω_e = [400] cm^{-1} $\omega_e x_e$ = [1.5] cm^{-1} σ = 1
B_e = [0.1519] cm^{-1} α_e = [0.0008] cm^{-1} r_e = [2.23] Å

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as 40.8 kcal mol^{-1} by Gordon (1) with white (α) phosphorus as the reference state.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon (1).

LEAD BROMIDE (PbBr) IDEAL GAS M_r = 287.104

$S°(298.15\ K) = 272.47 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 79.91 \pm 42\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 70.92 \pm 42\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
X $^2\Pi_{1/2}$	0	2
$^2\Pi_{3/2}$	[8300]	2
A [$^2\Sigma$]	20884.3	[2]
B [$^2\Sigma$]	34523.7	[2]

$\omega_e = 206.56\ cm^{-1}$ $\omega_e x_e = 0.495\ cm^{-1}$ $\sigma = 1$

$B_e = 0.0451\ cm^{-1}$ $\alpha_e = [0.00014]\ cm^{-1}$ $r_e = 2.546$ Å

Enthalpy of Formation

$\Delta_f H°(0\ K)$ = 19.10±10 kcal mol^{-1} (79.914±42 kJ mol^{-1}) is calculated and rounded from the D_0^0 = 2.43 eV (56.04 kcal mol^{-1}) determined by Singh from emission spectra (1), $\Delta_f H°$(Pb, g, 0 K) = 46.91±0.13 kcal mol^{-1} (2), and $\Delta_f H°$(Br, g, 0K) = 28.188 kcal mol^{-1} (2). Rosen (3) and Gaydon (4) recommended 57±9 kcal mol^{-1} and 58±9 kcal mol^{-1}, respectively, for D_0^0. A linear Birge-Sponer extrapolation of the ground state vibrational constants, as derived from absorption spectra (v, 0-11) observed by Morgan (5), gives a dissociation energy of 2.66 eV. Correction for the ionic character of PbBr as proposed by Hildenbrand (6) gives D_0^0 = 2.44 eV which is in good agreement with the value determined by Singh (1). $\Delta_f H°(298.15\ K)$ = 16.95±10 kcal mol^{-1} is calculated from the adopted $\Delta_f H°(0\ K)$ = 19.10±10 kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational constants are from the compilation of Rosen (3), corrected for the natural isotopic abundance of ^{79}Br and ^{81}Br. Analogous to PbF (2) and PbCl (2), a $^2\Pi_{3/2}$ state at 8300 cm^{-1} is added to the electronic states and levels listed by Rosen (3). The assignment of the first excited state remains uncertain; the choice appears to be between $^2\Sigma$ state, tentatively assigned to PbF (2) and PbCl (2), and $^2\Delta$, tentatively assigned to PbI (2). The $^2\Sigma$ state is adopted. The entropy is increased by 0.009 cal K^{-1} mol^{-1} at 4000 K and 0.012 cal K^{-1} mol^{-1} at 6000 K if the $^2\Delta$ state is used. The adopted value of B_e was determined by Lal and Khanna (7) and is adjusted for the natural abundance of the bromine isotopes. The value of r_e is calculated from the adopted B_e. The value of α_e is calculated assuming a Morse potential function.

Enthalpy of Formation

Kuznetsova and Kuzyakov (1) suggested a value of D_0^o = 85.8±11.4 kcal mol^{-1} based on linear Birge-Sponer extrapolations of the ground state and B' $^2\Delta$ state vibrational data. We correct this value for the ionic character of the bond according to Hildenbrand (2) and obtain D_0^o = 77.3±10.3 kcal mol^{-1}. With auxiliary JANAF data (3) this yields the adopted $\Delta_f H°(0\ K)$ = 57.543 kcal mol^{-1} (240.760 kJ mol^{-1}). Tandon and Tandon (4) obtained D_0^o = 85.3 kcal mol^{-1} from a theoretical treatment based on Sutherland's potential function in good agreement with the adopted value. The value of D_0^o may be compared to the average (per bond) enthalpy of atomization of 80.58 and 77.89 kcal mol^{-1} for $SiBr_2(g)$ and $SiBr_4(g)$, respectively (3).

Heat Capacity and Entropy

Molecular constant data for the ground state are from Mishra and Khanna (5). The vibrational data is in good agreement with data from Rao and Haranath (6), Kuznetsova et al. (7), and Jevons and Bashford (8). Data for the A $^2\Sigma$ and B' $^2\Delta$ states are from Rao and Haranath (6) and Kuznetsova and Kuzyakov (1), respectively. The B $^2\Sigma$ state data are from Mishra and Khanna (5) and the vibrational data agree well with Jevons and Bashford (8). Slightly different values for the rotational constants for both this state and the ground state have been obtained by Kuznetsova and Kuzyakov (9). Data for the C $^2\Pi$ state is from Oldershaw and Robinson (10) who also reported data for several higher states; these are not included due to uncertainties in their assignments and degeneracies. Splittings of 18 and 12 cm^{-1} for the B' $^2\Delta$ and C $^2\Pi$ states (1, 10), respectively, have not been included in our calculations. The $^4\Sigma$ state observed for SiF and SiI has not been observed for SiBr. It is expected to lie near 24000 cm^{-1} by analogy with SiF and SiI (3) which is very near the B' $^2\Delta$ state. This raises the possibility that this state may have been missed, or the $^2\Delta$ state misassigned, due to the large number of lines in this region (1). A high resolution re-examination of this region of the spectrum is desirable to clarify the situation. We have assigned an uncertainity of ±0.05 cal K^{-1} mol^{-1} to S°(298.15 K) in view of these uncertainties. All molecular constant data has been corrected to the natural abundances of Si and Br assuming the observed data was for $^{28}Si\ ^{79}Br$. The ground state is treated as two distinct levels due to the splitting of this state as expressed by the spin coupling constant (A = 419.2 cm^{-1}). This approximation gives slightly biased results at low temperature: the stated uncertainty in S°(298.15 K) should account for this.

Enthalpy of Formation

The selected value, $\Delta_f H°(298.15\ K) = -21.3\ kcal\ mol^{-1}$ ($-89.119\ kJ\ mol^{-1}$), is obtained from an analysis of spectroscopic data. Herzberg (1) suggested $D_0^0 = 2.8$ eV for SrBr(g) which was derived from a linear Birge-Sponer extrapolation of the ground state vibrational levels. Later, Gaydon (2) claimed that this value is unreliable and suggested that the true value may be much higher. The adopted ground state vibrational constants give $D_0^0 = 2.84$ eV by a similar extrapolation. We note that JANAF analyses (3) of the spectroscopic and thermochemical data for SrF(g) and SrCl(g) show that the ionicity corrections of Hildenbrand (4) bring the Birge-Sponer extrapolations into reasonable agreement with adopted D_0^0 values. Based on this correction for SrBr(g), we obtain $D_0^0 = 3.76$ eV ($86.7\ kcal\ mol^{-1}$) which is adopted. The adopted value of D_0^0 corresponds to $\Delta_f H°(298.15\ K) = 21.3\ kcal\ mol^{-1}$. We also find $D_0^0(SrBr)/\Delta_{at}H°(SrBr_2) = 0.46$ which is quite consistent with values of this ratio for other alkaline earth halide systems (5).

Ionic model calculations (6, 7) have led to D_0^0 values of 5.07 eV (6) and 3.53 eV (7). The latter result is believed to represent a minimum value for D_0^0. Two other experimental values for D_0^0 which bracket the selected value, have been reported. Flame studies (8) gave $D_0^0 = 3.4$ eV, and chemiluminescence (9) from reaction of Sr atoms with Br_2 gave a lower limit to D_0^0 of 4.1 eV. We assign an uncertainty of $\pm 10\ kcal\ mol^{-1}$ to $\Delta_f H°(298.15\ K)$ to include the possibility that these studies are correct.

Heat Capacity and Entropy

The value of r_e is obtained from that for gaseous $SrBr_2$ (3) with $r_e(SrBr)/r_e(SrBr_2) = 0.96$. This value for the ratio is calculated from bond lengths (5) for several other alkaline earth halide systems. Our adopted value for r_e agrees with that (2.74 Å) estimated by Krasnov and Karaseva (7), while two other estimated values (6) 10] lie somewhat higher (~0.2 Å). The rotational constant is calculated from the estimated value for r_e. The value of α_e is obtained from a Morse potential function.

The vibrational constants and first seven electronic states and levels are taken from the compilation of Rosen (11). The E state energy has been measured by Reddy and Rao (12), while the F, G, and H state energies are due to Reddy et al. (13). The five uppermost states were associated with transitions between the excited states of SrBr, and their assignments (13) were made by analogy with the observed spectrum for SrCl(g).

Enthalpy of Formation

$\Delta_f H°(TiBr, g, 298.15\ K)$ is calculated from the dissociation energy which is estimated as 104 kcal mol^{-1}. This estimate is obtained from the relation $\Delta_{at}H°(TiBr_4) < D_0^0(TiBr) < \Delta_{at}H°(TiBr_3)$, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF_2(g) by Zmbov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e, and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interatomic distance is estimated from Guggenhemier's relation (2). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+(3). α_e is estimated from the Morse potential function.

TUNGSTEN BROMIDE (WBr) IDEAL GAS M_r = 263.754

$S°(298.15\ K) = [272.6]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [593.7 \pm 84]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [586.2 \pm 84]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$[^2\Delta]$	0	[4]
	[5000]	[2]
	[15000]	[20]

$\omega_e = [321.4]\ cm^{-1}$ $\omega_e x_e = [0.80]\ cm^{-1}$ $\sigma = 1$

$B_e = [0.05254]\ cm^{-1}$ $\alpha_e = [0.00015]\ cm^{-1}$ $r_e = [2.40]$ Å

Enthalpy of Formation

$\Delta_f H°(WBr, g, 298.15\ K) = 140.1\ kcal\ mol^{-1}$ ($586.178\ kJ\ mol^{-1}$) is calculated from the bond dissociation energy, $\Delta_{at}H°(W\text{-}Br, 298.15\ K) = 90 \pm 20\ kcal\ mol^{-1}$. This value is estimated to be slightly higher than the average bond dissociation energy of $WBr_6(g)$, by analogy with the WCl_x system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in $WBr_6(g)$. The distance is then used with Guggenheimer's relation (1) for polar molecules to calculate the fundamental vibrational freqency, ω_e. The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/(D° + 0.5\ \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for WF(g) (2).

ω_e = [317] cm^{-1} $\omega_e x_e$ = [0.69] cm^{-1} σ = 1

B_e = [0.065] cm^{-1} α_e = [0.00018] cm^{-1} r_e = [2.47] Å

Enthalpy of Formation

$\Delta_f H°(ZrBr, g, 298.15\ K)$ = 72 kcal mol^{-1} (301.248 kJ mol^{-1}) is derived from the estimated bond dissociation energy, $\Delta_{at}H°$ (Zr-Br, 298.15 K) = 103.5±10 kcal mol^{-1}. This value of is calculated from the relation $\Delta_{at}H°$(Zr-Br, 298.15 K)/ $\Delta_{at}H°$(Ti-Br, 298.15 K) = $\Delta_{at}H°$(ZrBr4, 298.15 K)/Δ_{at} H°(TiBr4, 298.15 K) where the average bond dissociation energies, $\Delta_{at}H°(ZrBr_4$, 298.15 K = 102.2 kcal mol^{-1}, $\Delta_{at}H°(TiBr_4$, 298.15 K) = 87.9 kcal mol^{-1} and $\Delta_{at}H°$(TiBr, 298.15 K) = 89.0 kcal mol^{-1}, all calculated from JANAF $\Delta_f H°$(298.15 K) for $ZrBr_4$(g), $TiBr_4$(g), TiBr(g), Zr(g), Ti(g) and Br(g).

Heat Capacity and Entropy

The bond distance is assumed to be the same as that in $ZrBr_4$(g), which was estimated as 2.47 Å by Godnev et al. (1). The estimated bond distance is then used with Guggenheimer's (2) relation for polar molecules to calculate the fundamental frequency ω_e. The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4\ (\Delta_{at}H° + 0.5\ \omega_e) = 0.0021$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function.

The ground state configuration is taken from the ground state multiplet of Zr^+ reported by Moore (3). The electronic levels and quantum weights are estimated to be the same as those of ZrF(g).

PREVIOUS: September 1961 (1 atm) CURRENT: June 1982 (1 bar)

Bromine (Br_2) Br_2(ref)

$S°(298.15\ K) = 152.21 \pm 0.04\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 265.90 \pm 0.05\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 10.571 \pm 0.008\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity for crystalline and liquid bromine was measured by Hildenbrand et al. (1), 179 data points in the range 15-310 K. The reported values are corrected for the current relative molecular weight and converted to joules. The liquid phase heat capacity is extrapolated to a constant value of 18.0 cal K^{-1} mol^{-1} for temperatures above 320 K. The value recommended by CODATA (2) for $S°(Br_2, \ell, 298.15\ K)$ is the same as adopted here and is based on the same study. References to earlier work are given by Hildenbrand et al. (1). They are not used in this analysis.

Fusion Data

The adopted values for the fusion point and the enthalpy of fusion are from the study of Hildenbrand et al. (1).

Vaporization Data

The enthalpy of vaporization of bromine at 25°C was measured by Hildenbrand et al. (1). Six vaporization determinations were made using 14 to 18 gram samples of bromine. Correcting their reported values for the current relative atomic mass and converting to Joules yields $\Delta_{vap}H°(Br_2, \ell, 298.15\ K) = 30.91 \pm 0.11\ kJ\ mol^{-1}$. CODATA (2) has recommended the same value based on the same study.

Vapor pressure studies include: Fischer and Bingle (298-389 K, 3), Frey and Gregory (177-195 K, 4), Henglein, et al. (177-241 K, 5), Ramsay and Young (256-329 K, 6) and Scheffer and Voogd (253-362 K, 7). For the liquid region, the data of Fischer and Bingle (3) and Scheffer and Voogd (7) show a decided decrease of $\Delta_{vap}H°$ with increasing temperature. The data of Ramsey and Young (6) show only a small temperature trend and are in good agreement with the adopted calorimetric study. For the crystal region, the data are too scattered to be conclusive.

Enthalpy of Formation

We adopt the enthalpy of formation values of CODATA (6) as follows: $\Delta_f H°(298.15\ K)$ = 30.91 ± 0.11 kJ mol^{-1} and $\Delta_f H°$ (0 K) = 45.71 ± 0.12 kJ mol^{-1}. These values were based on the heat capacity and enthalpy of vaporization measurements of Hildenbrand et al (7). Note that the latter value of $\Delta_f H°$ is deduced from the former using the CODATA values of H°(298.15 K) - H°(0 K) for $Br_2(g)$ and $Br_2(\ell)$. Our calculated value of H°(298.15 K) - H°(0 K) for $Br_2(g)$ is only 1.3 J mol^{-1} smaller than the recommended value of CODATA. Our adopted dissociation energy for the natural abundance mixture is derived from the isotopic values reported by Barrow et al. (1) as given by Huber and Herzberg (see reference (3)). The CODATA value for $D_0^0(Br_2, g)$, as deduced from the $\Delta_f H°(0\ K)$ data for $Br_2(g)$ and Br(g), is 190.14 kJ mol^{-1}. The 0.01 kJ mol^{-1} discrepancy is due to CODATA'S adoption of D_0^0 for $^{79}Br^{81}Br$ based on earlier work of Horsley and Barrow (8). Refer to the monatomic bromine gas table for additional discussion of the dissociation energy.

Heat Capacity and Entropy

The thermal functions are calculated using a direct summation technique. Included in the calculation are the ground state plus the four lowest lying excited states. Spectroscopic constants for the ground state are taken from Barrow, et al. (1) for $^{79}Br_2$ *while the excited state constants are from Gurvich et al. (2-4). Note that Barrow, et al. (1) presented constants for the* $^3\Pi_{0_u^+}$ state of $^{79}Br_2$ for $v \leq 10$ only. Therefore for this state we adopted the constants of Gurvich, et al. (2) which are fit to the experimental data up to the dissociation limit. For the ground state and the $^3\Pi_{1u}$ and $^3\Pi_{0^+u}$ excited states, the calculation is performed including the quasi-bound rotational levels above the dissociation limit (see $Cl_2(g)$ table) using J_{lim} and v_{max} given by Gurvich et al. (2).

Splitting of the rotational levels due to the rotational-electronic interaction in the $^3\Pi_{2u}$ and $^3\Pi_{1u}$ states is taken into account only insofar as the statistical weight of the rotational levels is doubled. The rotational levels are extrapolated to high J values according to the method of Khachkuruzov (9) who proposed a simpler form of Wooley's method (10).

The spectroscopic constants for the hypothetical natural abundance species are determined from the $^{79}Br_2$ constants using a standard reduced mass scaling scheme. The calculated value of S°(298.15 K) is 0.07 J mol^{-1} K^{-1} smaller than that adopted by CODATA (6) and also by Gurvich et al. (2). For this comparison, the entropy value reported by CODATA and Gurvich is increased by 0.1094 J K^{-1} mol^{-1} to account for a change in the standard state pressure from 1 atm to 1 bar.

$\Delta_f H°(0\ K) \approx$ Unknown

$\Delta_f H°(298.15\ K) = -683.2 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 29.079 \pm 0.63\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation is the mean of three values derived from two independent paths. One path involves the enthalpy of solution of Ca(cr) and $CaBr_2$(cr) in HBr·555 H_2O which were measured by Ehrlich et al. (1). Recalculation of their results using recent thermal data (2) 3) for aqueous HBr yields $\Delta_f H°(CaBr_2, cr, 298.15\ K) = -164.0$ kcal mol^{-1}. The uncertainty in this value could approach ±1.0 kcal mol^{-1} due primarily to the rather impure metal (99.3% free Ca) used in these measurements.

An alternate path used to obtain values for $\Delta_f H°$ involves the results of measurements on the enthalpy of solution of $CaBr_2$ (cr) in aqueous solution. The work (4-6) reported in this area has been reviewed by Bichowsky and Rossini (7). Recalculation of these results using $\Delta_f H°(Ca^{+2}, \infty\ aq, 298.15\ K) = -129.74$ kcal mol^{-1} (8) and $\Delta_f H°(Br^-, \infty\ aq, 298.15\ K) = -29.039 \pm 0.036$ kcal mol^{-1} (2) yields values for $\Delta_f H°$ of $CaBr_2$(cr) in kcal mol^{-1} of -162.3 (4), -160.2 (5), and -163.6 (6). The disagreement in these values is disturbing but can be mostly accounted for when one considers the difficulties involved in the preparation (6) of "pure" anhydrous $CaBr_2$.

A mean value (-163.3 kcal mol^{-1}, 683.247 kJ mol^{-1}) for $\Delta_f H°(CaBr_2, cr, 298.15\ K)$ of three results (1, 4, and 6) is preferred because of the difficulties reported in obtaining and keeping samples free of impurities. NBS (8) has selected essentially the same value (-163.2 kcal mol^{-1}) from their analysis of the available data.

Heat Capacity and Entropy

No low temperature $C_p°$ data have been reported for $CaBr_2$; thus, the value of S°(298.15 K) must be estimated. Application of the Berthelot principle (9) to the process $SrBr_2$(cr) + Ca(cr) = $CaBr_2$(cr) + Sr(cr) gives S°(298.15 K) = 31.7±1.5 cal K^{-1} mol^{-1} for $CaBr_2$. Auxiliary entropies are taken from the JANAF Tables (10). Also, JANAF entropies (10) for the other three calcium dihalides suggest a value near 30.5 cal K^{-1} mol^{-1} for $CaBr_2$. We adopt S°(298.15 K) = 31±1 cal K^{-1} mol^{-1} which is the value selected by NBS (8). Other reported estimates for S°(298.15 K) in cal K^{-1} mol^{-1} are 32.0±2.8 (11), 32.2±0.7 (12), and 33 (13).

$C_p°$ at 298.15 K has not been measured. However, Janz et al. (14) measured relative enthalpies (434-1013 K) for $CaBr_2$ and reported the results in equation form. Their equation gives $C_p° = 16.3$ cal K^{-1} mol^{-1} at 298.15 K which appears to be too low by about 2 units when compared with JANAF $C_p°$ data for several other alkaline earth dihalides. The only other enthalpy study that has been reported is that of Dworkin and Bredig (15) who measured H°(1015 K)-H°(298.15 K) = 14.00 kcal mol^{-1} in a copper block drop-calorimeter. We adopt this result. JANAF data (10) are used to obtain $C_p°$ at 298.15 K from the process $CaCl_2$(cr) + 2 KBr(cr) = $CaBr_2$(cr) + 2 KCl(cr) by assuming $\Delta C_p° = 0$. Data in the temperature range 300-1013 K are estimated by comparison with those for CaF_2 and $CaCl_2$ (10). More weight is given to the results for $CaCl_2$, since it has the same crystal structure (15) as $CaBr_2$ and nearly the same melting temperature (1045 K) (10) and enthalpy H°(1045 K)-H°(298.15 K) = 14.2 kcal mol^{-1} (10) at T_{fus} as does $CaBr_2$. The $C_p°$ estimates are also made so as to reproduce as closely as possible the adopted enthalpy at 1015 K. Our estimated $C_p°$ data give a value of H°(1015 K)-H°(298.15 K) = 13.994 kcal mol^{-1} which agrees with the measured value (15) to within 6 cal mol^{-1}. $C_p°$ data above 1015 K are obtained by graphical extrapolation. The enthalpies obtained from the equation of Janz et al. (14) are systematically lower than our adopted values. The deviation is ~0.4% at 1015 K; it increases at lower temperatures and reaches a maximum value of -2.7% at 600 K.

Fusion Data

See the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ is calculated as the difference in the adopted enthalpies of formation for the ideal gas and crystal at 298.15 K.

PREVIOUS: CURRENT: June 1974

$S°(298.15\ K) = [147.861]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1015\ K$

$\Delta_f H°(298.15\ K) = [-662.989]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 29.079 \pm 0.63\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding of $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1015\ K) - H°(298.15\ K)$, between the crystal and liquid. Toguri et al. (1) have reported a K_p value for the anion exchange equilibrium $0.5\ CaBr_2(\ell) + HCl(g) = 0.5\ CaCl_2(\ell) + HBr(g)$ at 1073 K. A 3rd law analysis of this single value gives $\Delta_r H°(298.15\ K) = -0.22$ kcal mol^{-1} with JANAF functions. The 3rd law enthalpy leads to $\Delta_f H°(\ell, 298.15\ K) = -157.9$ kcal mol^{-1} which supports our adopted value by an independent path.

Heat Capacity and Entropy

$C_p°$ of the liquid above 700 K is the value (27.0 cal $K^{-1}\ mol^{-1}$) determined by Dworkin and Bredig (2) from enthalpy measurements in the vicinity of the melting point. A similar enthalpy study (1013-1132 K) by Janz et al. (3) suggests only a slightly higher value (27.38 cal $K^{-1}\ mol^{-1}$) for $C_p°$ of $CaBr_2(\ell)$. A glass transition is assumed at 700 K below which $C_p°$ is that of the crystal.

The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The adopted value of T_{fus} is that measured calorimetrically by Dworkin and Bredig (2). Similar measurements by Janz et al. (3) gave essentially the same value (1013 K). Other reported values for T_{fus} are 1018 K (4), 1003 K (5-7), and 1016 K (8).

$\Delta_{fus} H°$ is that measured by Dworkin and Bredig (2) in a copper block drop-calorimeter. Another calorimetrically determined value (3)($\Delta_{fus} H° = 6.86 \pm 0.09$ kcal mol^{-1})] and one based on cryoscopic measurements (4)($\Delta_{fus} H° = 7.03 \pm 0.35$ kcal mol^{-1})] bracket the selected value.

Vaporization Data

T_{vap} (f = 1 bar) is the temperature at which $\Delta_r G°$ for the process $CaBr_2(\ell) = CaBr_2(g)$ approaches zero. $\Delta_{vap} H°$ is the difference in the enthalpies of formation of the gas and liquid at T_{vap}. Peterson and Hutchison (9) obtained T_{vap} = 2088 K (at 1 atm) from vapor pressure measurements on the liquid (1149-1321 K). This value is nearly identical to our result.

CALCIUM BROMIDE ($CaBr_2$) IDEAL GAS M_r = 199.888

$S°(298.15\ K) = [314.8 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -370.5 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -384.9 \pm 8.4\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[148](1)
[47](2)
330 (1)

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Ca-Br = 2.67 ± 0.03 Å Bond Angle: Br-Ca-Br = 180°

Rotational Constant: $B_o = 0.014797\ cm^{-1}$

Enthalpy of Formation

The selection of $\Delta_f H°(298.15\ K) = -92.0 \pm 2.0$ kcal mol^{-1} (-384.928 ± 8.4 kJ mol^{-1}) for $CaBr_2(g)$ is based on results derived from two independent means. Peterson and Hutchison (1, 2) have reported results of an extensive study of the vapor pressures (1149-1321 K) for liquid $CaBr_2$. Measurements were made by the Knudsen effusion method on a sample which had been prepared by direct union of high purity elements. X-ray diffraction patterns on the final product showed no metal or oxide lines. Schofield and Sugden (3) investigated the equilibrium $Ca(g) + 2\ HBr(g) = CaBr_2(g) + 2\ H(g)$ in H_2-O_2-N_2 flames and reported K_p data for temperatures in the range 2137-2532 K. Results of our 2nd and 3rd law analysis of these data are tabulated below. We assume that the dibromide monomer is the only vapor species produced in the volatilization of $CaBr_2(\ell)$. Support for this assumption is provided by mass spectra for some of the other alkaline earth dihalides (4). These studies indicate that the saturated vapors consist predominately of the metal dihalide monomer and agree with predictions which were made by Brewer et al. (5) for these dihalide molecules. Included in the table for comparison are results of our analysis of older vapor pressure data (6),7) which have been reviewed by Brewer et al. (5).

Source	Method	Reaction	Data Points	T/K	$\Delta_r H°$, kcal mol^{-1} 2nd law	3rd Law	Drift cal $K^{-1}mol^{-1}$	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

Brewer (5, 7)	Boiling Point	A	2	1180;1480	62.5	64.76 ±0.7	1.7	-93.7 ± 1.7
Schofield and Sugden (3)	Flame	C	8(a)	2137-2532	-9.4	-14.38 ±1.7	-2.1 ±3.2	-93.3 ± 2.0
		K_p						

Reactions: (A) $CaBr_2(\ell) = CaBr_2(g)$ (B) $CaBr_2(cr) = CaBr_2(g)$ (C) $Ca(g) + 2\ HBr(g) = CaBr_2(g) + 2\ H(g)$

(a) One point rejected due to failure of a statistical test.

In the selection of $\Delta_f H°$, no weight is given to those measurements made prior to 1965. Also, we note that Schofield and Sugden (3) reported in the same paper similar results for $SrCl_2$ and $BaCl_2$ which lead to $\Delta_f H°$ values that are quite consistent with JANAF enthalpies of formation (4). We, therefore, choose to select an average value of the results of Peterson and Hutchison (1, 2) and Schofield and Sugden (3). An earlier analysis (14) of the vapor pressure data (1, 2) with older functions (5) gave $\Delta_f H°$ of -95.2 kcal mol^{-1}.

Heat Capacity and Entropy

The bond length is from the high-temperature electron diffraction work of Akishin and Spiridonov (8). Electron diffraction patterns (8) were satisfactorily explained on the basis of a linear model (180° ± 10°). Later studies by Wharton et al. (9), using electric deflection of molecular beams to detect dipole moments, showed no polarity in the $CaBr_2$ molecule. The absence of dipolar character is most reasonably explained by a linear and centrosymmetric configuration.

The antisymmetric stretching frequency (ν_3) was observed in the high-temperature infrared spectra of $CaBr_2$ vapor by Baikov (10). The symmetric stretching (ν_1) and bending (ν_2) frequencies are calculated from force constants by the valence force method (11). The observed value of ν_3 gives $k = 1.028 \times 10^5$ dynes/cm which leads to $\nu_1 = 148\ cm^{-1}$. Other estimates that have been reported for ν_1 (in cm^{-1}) are 148 (10), 164 (5), and 172 (13). A comparison of values for the ratio of the stretch to bend force constants for the linear molecules $CaCl_2$ (4)(ratio = 81)] and $SrBr_2$ (4)(ratio = [100])] suggests a value near 100 for $CaBr_2$. This value for the ratio gives $k\delta/\ell^2 = 1.028 \times 10^3$ dynes/cm, or $\nu_2 = 47\ cm^{-1}$. However, similar data for $BeBr_2$ (12) indicate that the value of the ratio could be as low as 41. This leads to a $\nu_2 = 73\ cm^{-1}$ which agrees with the value (85 cm^{-1}) recommended by Krasnov and Svettsov (13). Brewer et al. (5) choose $\nu_2 = 52\ cm^{-1}$. We prefer the lowest value of ν_2 (47 cm^{-1}) at this time but include in the uncertainty (± 2.0 cal $K^{-1}mol^{-1}$) assigned to the value of $S°(298.15\ K)$ the possibility that the highest value (85 cm^{-1}) is correct. The singlet ground state is assigned by analogy with that for $BaCl_2$ (4).

PREVIOUS: June 1974 (1 atm) CURRENT: June 1974 (1 bar)

$S°(298.15\ K) = 140.67 \pm 1.3\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 650\ K$
$T_{fus} = 964\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -248.9 \pm 2.1\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0.4184\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [50.208 \pm 13]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpies of solution of Fe(cr), $Br_2(\ell)$ and $FeBr_2$(cr) in Br_2-KBr aqueous solution were measured by use of an ice calorimeter by Hieber and Woerner (1). From the results obtained, the enthalpy of formation for $FeBr_2$(cr) was reported to be -59.87 kcal mol^{-1}. *The enthalpies of solution of $FeBr_2$(cr) in water were determined by Li and Gregory (2) and by Paoletti (3)* to be -20.1±0.4 and -20.06±0.06 kcal mol^{-1}, respectively. Using $\Delta_f H°(298.15\ K)$ = -29.05 and -21.3 kcal mol^{-1} for Br^-(aq, ∞) and Fe^{++}(aq, ∞), the corresponding $\Delta_f H°(298.15\ K)$ for $FeBr_2$(cr) were calculated as -59.3 and -59.34 kcal mol^{-1}. The value of $\Delta_f H°(Br^-, aq, ∞, 298.15\ K)$ was taken from (4). The value of $\Delta_f H°(Fe^{++}, aq, ∞, 298.15\ K)$ was derived from enthalpies of solution and formation for $FeCl_2$(cr) using $\Delta_f H°(Cl^-, aq, ∞, 298.15\ K)$ = -39.952 kcal mol^{-1} from (4).

The value of $\Delta_f H°(FeBr_2, cr, 298.15\ K)$ adopted is -59.5±0.5 kcal mol^{-1} (-248.948±2.1 kJ mol^{-1}).

Heat Capacity and Entropy

The heat capacities, 323-633 K, were measured by Gregory and O'Neal (5). *Those for temperatures below 232 K and above 633 K were estimated by linear extrapolation.* Low temperature $C_p°$, 12-110 K, were reported by Miljutin and Nachimowitsch (6). However, these data are inadequate for obtaining an accurate entropy at 298.15 K. The adopted S°(298.15 K) value was reported by Gregory and MacLaren (7) *and was obtained from Westrum (8). A magnetic transition at 11 K was reported by Bizette et al.* (9).

Transition Data

T_{trs} and $\Delta_{trs} H°$ were taken from Gregory and O'Neal (5).

Fusion Data

T_{fus} adopted was reported by MacLaren and Gregory (10). The value was calculated from the vapor pressure equations and is slightly above 684°C (957 K) reported by Ferrari et al. (11). *However, it agrees well with 962±2 K obtained by the* differential thermocouple cooling curve analysis (10). The $\Delta_{fus} H°$ value was estimated from the vapor pressure data in order to obtain good agreement between the 2nd and 3rd law heats of vaporization. See the $FeBr_2$(g) table for details.

Sublimation Data

$\Delta_{sub} H°$(monomer → 298.15 K) is calculated as the difference between $\Delta_f H°(298.15\ K)$ for $FeBr_2$(g) and $FeBr_2$(cr). $\Delta_{sub} H°$(dimer → 298.15 K) is calculated as the difference between those for Fe_2Br_4(g) and 2 $FeBr_2$(cr).

IRON BROMIDE ($FeBr_2$) LIQUID M_r = 215.655

$S°(298.15\ K)$ = [169.376] J K^{-1} mol^{-1}

T_{fus} = 964 K

$\Delta_f H°(298.15\ K)$ = [-211.005] kJ mol^{-1}

$\Delta_{fus} H°$ = [50.208 ± 13] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(964\ K) - H°(298.15\ K)$, between $FeBr_2(cr)$ and $FeBr_2(\ell)$.

Heat Capacity and Entropy

The heat capacity is assumed to be constant in the temperature range from 298.15 to 2000 K and is estimated on the basis of 8.5 cal K^{-1} mol^{-1} per atom. $S°(298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which the total pressure of $FeBr_2(g)$ and $Fe_2Br_4(g)$ over $FeBr_2(\ell)$ equals one bar. Based on the vapor composition and the values of $\Delta_{vap} H°$ for both the monomer and dimer at T_{vap} for both the monomer and dimer at T_{vap}, the enthalpy of vaporization is derived.

Rotational Constant: B_o = [0.021023] cm^{-1}

Enthalpy of Formation

The vapor pressures of $FeBr_2$(cr) and $FeBr_2$(ℓ) have been measured in the temperature range from 623.15 to 962.15 K (1) 2). Using the reported data the corresponding enthalpy changes for the reactions (A) $FeBr_2$(cr) = $FeBr_2$(g) and (B) $FeBr_2$(ℓ) = $FeBr_2$(g) were evaluated by both the 2nd and 3rd law methods. The results obtained are presented in the following table. The values of $\Delta_f H°(298.15\ K)$ for $FeBr_2$(g) are calculated based on the 3rd law values for $\Delta_r H°(298.15\ K)$. The value of $\Delta_f H°(298.15\ K)$ for $FeBr_2$(g) adopted is -9.9 ± 0.5 kcal mol^{-1} (-41.422 kJ mol^{-1}).

(2)	Torsion-Effusion	(A)	670.0 - 740.0	49.11	49.59	+ 0.71	-9.91
(1)	Diaphragm	(B)	962.15-1182.15	39.77	40.84	+ 0.93	-9.59

Heat Capacity and Entropy

The molecular structure was assumed to be linear. The electronic levels and quantum weights were estimated by comparison with those for $FeCl_2$(g) reported by DeKock and Gruen (3). The bond distance was estimated by Brewer et al. (4). The vibrtional frequencies were estimated in order to obtain good agreement between the 2nd and 3rd law enthalpies of sublimation and vaporization.

Ground State Quantum Weight: [1] σ = [2]
Point Group: [C_{2v}]
Bond Distances: Si-H = [1.49] Å Si-Br = [2.19] Å
Bond Angles: H-Si-H = [111]° Br-Si-Br = [110]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [6.36266 x 10^{-113}] g^3 cm^6

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated by linear interpolation between the values (1) of $SiBr_4(g)$ and $SiH_4(g)$. The only experimental $\Delta_f H°$ for $SiHBr_3(g)$ appears to be too uncertain to justify a nonlinear interpolation such as that adopted for SiH_3Cl (1). Normally we would seek a comparison with $\Delta_f H°$ values of CH_nBr_{4-n}. These were recently reviewed by Kudchadker and Kudchadker (2). They adopted a cubic variation of $\Delta_f H°$ with n, based on $\Delta_f H°$ values of $CHBr_3$ and CBr_4 selected by Wagman et al. (3). We presume that Wagman's values are calculated rather than experimental. Uncertainty in these values (4 - 6) precludes their use as a comparison for SiH_nBr_{4-n}. We conclude, as did Hunt and Sirtl (7), that the available data justify only linear interpolation of $\Delta_f H°$.

Heat Capacity and Entropy

The molecular structure is estimated by comparison with SiH_3Br, $SiHBr_3$ and the chlorosilanes (1). Bond distances are assumed to be intermediate between those of SiH_3Br and $SiHBr_3$ (1). The principal moments of inertia are I_A = 7.9748 x 10^{-39}, I_B = 85.9075 x 10^{-39} and I_C = 92.8728 x 10^{-39} g cm^2.

Vibrational frequencies are those selected by Shimanouchi (8) based on gas-phase infrared spectra (9) and liquid-phase Raman spectra (10). Gas-phase frequencies are adopted except for ν_4 = 122 cm^{-1} and infrared inactive ν_5 = 688 cm^{-1}.

We neglect excited states and assume the electronic ground state to be a singlet. We expect that contributions from excited states should be unimportant, as discussed on the tables for SiH_3Br and SiH_2Cl_2 (1).

MERCURY BROMIDE ($HgBr_2$) CRYSTAL M_r = 360.398

$S°(298.15\ K) = [170.314 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 514\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -169.45 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.908 \pm 0.33\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is taken from (1).

Heat Capacity and Entropy

$C_p°$ is assumed to be a linear function of temperature and is fitted to the data of Guinchant (2) and Janz and Goodkin (3). The entropy is estimated by adjusting its value until the melting, sublimation, and vaporization data are in agreement.

Fusion Data

T_{fus} is from (1); $\Delta_{fus} H°$ is from Janz and Goodkin (3).

$S°(298.15\ K) = [192.172]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} \approx 514\ K$

$\Delta_f H°(298.15\ K) = [-156.626]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.908 \pm 0.33\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(514\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is obtained from the data of Janz and Goodkin (1) in the range 507-544 K; it is assumed constant above and below this range. $S°(298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion and Vaporization Data

T_{fus} and T_{vap} (1 atm) are from (2). $\Delta_{fus} H°$ is the value given by Janz and Goodkin (1), and $\Delta_{vap} H$ (1 atm) is obtained from the data of Prideaux (3) and Johnson (4).

Mercury Bromide ($HgBr_2$) Br_2Hg_1(cr,l)

MERCURY BROMIDE ($HgBr_2$) IDEAL GAS M_r = 360.398

$S°(298.15\ K) = 320.223\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -67.26 \pm 84\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -85.45 \pm 8.4\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
225(1)
41(2)
293(1)

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: $D_{\infty h}$
Bond Distance: Hg-Br = 2.4 A
Bond Angle: Br-Hg-Br = 180°
Rotational Constant: $B_o = 10.018162\ cm^{-1}$

Enthalpy of Formation

$\Delta_f H°$(cr, 298.15 K) (1) is combined with the 3rd law $\Delta_{sub} H°(298.15\ K)$ derived from the data of Niwa and Shibata (2) and Johnson (3).

Heat Capacity and Entropy

The vibrational constants are those given by Klemperer and Lindeman (4). The bond length is an average of the values given by Braune and Knoke (5), Gregg et al. (6), and Akishin et al. (7).

MERCURY BROMIDE (Hg_2Br_2) CRYSTAL M_r = 560.988

$S°(298.15\ K) = 218.75 \pm 3.2\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -204.18 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

The average of the values obtained from the cell measurements of Dakin and Ewing (1) and Ishikawa and Ueda (2) is adopted.

Heat Capacity and Entropy

The heat capacity is estimated by analogy with Hg_2Cl_2(cr). The entropy was obtained from the Gibbs energy and enthalpy of formation (1, 2).

Sublimation Data

According to Jung and Ziegler (3), the vapor pressure over Hg_2Br_2(cr) reaches one atmosphere at 666 K where the vapor is dissociated into Hg(g) and $HgBr_2$(g).

Ground State Quantum Weight: 1 σ = [4]

Point Group: $[D_{2h}]$

Bond Distances: K-Br = [3.07] Å K-K = [1.94] Å Br-Br = [2.39] Å

Bond Angles: Br-K-Br = [102]° K-Br-K = [78]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.46082 \times 10^{-111}]\ g^3\ cm^6$

Enthalpy of Formation

Vapor densities and vapor pressures of KBr were measured, using a liquid gold isoteniscope, by Hagemark et al. (1), and Hagemark (2). Based on the equilibrium constants for the reaction $2KBr(g) = K_2Br_2(g)$ in the temperature range 1267-1434 K, the enthalpy change $\Delta_r H°(298.15\ K)$ of this reaction is evaluated by the 2nd and 3rd law methods to be -42.80±4.26 and -43.12 kcal mol^{-1}, respectively. The enthalpy of formation for $K_2Br_2(g)$ is calculated to be -129.2±4 kcal mol^{-1}, using the 3rd law $\Delta_r H°(298.15\ K)$ value and $\Delta_f H°(KBr, g, 298.15\ K)$ = -43.04 kcal mol^{-1}. The drift in the 3rd law $\Delta_r H°(298.15\ K)$ values is 0.01±3.2 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

The molecular structure and bond distances were estimated by Berkowitz (3), and are tentatively adopted. Berkowitz (4) has calculated vibrational frequencies on the basis of the potential function for an ionic model. These values ~~are adjusted~~ so that the 3rd law $\Delta_r H°(298.15\ K)$ value for the reaction $2KBr(g) = K_2Br_2(g)$ agrees with the 2nd law value. The prinicpal moments of inertia are: $I_A = 48.4690 \times 10^{-39}$, $I_B = 151.0555 \times 10^{-39}$ and $I_C = 199.5245 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

This was obtained from the enthalpy of formation of the liquid and the selected enthalpy of vaporization to the dimer, which derivation has been given in the LiBr(g) table.

Heat Capacity and Entropy

Berkowitz (1) has calculated the molecular structure and vibrational frequencies based on an ionic model. The planar rhombic structure for dimeric lithium bromide, proposed by Berkowitz, has been confirmed by the lack of polarity in electric deflection by Buchler et al. (2). The selected bond distances and angle were obtained from the electron diffraction studies of monomer-dimer vapor by Akischin and Rambidi (3). The bond distances (r_{Br-Br} = 4.20 Å and r_{Li-Li} = 2.60 Å) calculated by Berkowitz are in reasonable agreement with those selected. The principal moments of inertia are: I_A = 4.1882 x 10^{-39}, I_B = 98.3375 x 10^{-39} and I_C = 102.5257 x 10^{-39} g cm^2.

Bauer et al. (4) have estimated six vibrational frequencies (576, 576, 202, 230, 329 and 365 cm^{-1}) for Li_2Br_2(g) in the electron diffraction studies of Li_2Cl_2(g). Klemperer and Norris (5) have observed two fundamental vibrational frequencies (413 and 295 cm^{-1}) in the infrared spectrum and tentatively assigned them as B_{2u} and B_{3u} modes; and these have been adopted in the tabulation. The remaining four vibrational frequencies were obtained from Berkowitz (1) because his model and derivation are self-consistent.

$S°(298.15\ K) = [117.2 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 984 \pm 15\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -524.26 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [39.330 \pm 4.2]\ kJ\ mol^{-1}$

Enthalpy of Formation

The selected value for $\Delta_f H°(298.15\ K)$ is that given by NBS (1). This value is derived from the solution calorimetric measurements of Finch et al. (2). Their enthalpies for the reaction of crystalline MgO with aqueous HBr and solution of anhydrous $MgBr_2$ in the same solvent are combined to give $\Delta_r H°(298.15\ K) = 7.77 \pm 0.40$ kcal mol^{-1} for the process $MgO(cr) + 2\ HBr(aq) = MgBr_2(cr) + H_2O(\ell)$. When this result is combined with auxiliary data (1, 3, and 4), the selected value is obtained. This value is confirmed by an independent means. Bichowsky and Rossini (5) give the enthalpy of solution of $MgBr_2$ in 800 H_2O as -43.3 kcal mol^{-1} based on measurements by Beketoff (6). Correction of this value to 298.15 K and infinite dilution gives a value for $\Delta_{sol} H°$ which leads to $\Delta_f H°(298.15\ K) = -125.4$ kcal mol^{-1} when combined with $\Delta_f H°(Mg^{+2}, aq, \infty, 298.15\ K) = -111.58$ kcal mol^{-1} (1) and $\Delta_f H°(Br^-, aq, \infty, 298.15\ K) = -29.039 \pm 0.035$ kcal mol^{-1} (4).

Two emf studies (7, 8) on the potential of the magnesium electrode in ether solution give results in disagreement with the calorimetric values. From these cell data we derive $\Delta_f H°(298.15\ K)$ values of -118.8 kcal mol^{-1} (7) and -115.0 kcal mol^{-1} (8). These rather large discrepancies are taken as an indication that the electrodes are probably irreversible under these conditions. In fact one study (8) reported that from 10 to 20 hours were required before stable emf values were obtained.

Heat Capacity and Entropy

$C_p°$ at 298.15 K is obtained from the process $MgCl_2(cr) + 2\ NaBr(cr) = MgBr_2(cr) + 2\ NaCl(cr)$ by assuming $\Delta C_p°$ is zero. A comparison of the $C_p°$ value (17.49 cal $K^{-1}\ mol^{-1}$) with those for other alkaline earth dihalides shows that it is reasonable. $C_p°$ data above 300 K are estimated by comparison with similar data for $MgCl_2$ and CaI_2 (3).

Several estimates (9-12) lying in the range 27-30 cal $K^{-1}\ mol^{-1}$ for $S°(298.15\ K)$ have been reported. Available experimental data for several other alkaline earth dihalides suggest a value for $S°(298.15\ K)$ of $MgBr_2(cr)$ near 28 cal $K^{-1}\ mol^{-1}$ (117.152 J $K^{-1}\ mol^{-1}$). We tentatively adopt this value. It is also the value recommended by Kelley and King (10) and NBS (1).

Fusion Data

The value of T_{fus} is that determined from cooling curves by Kellner (13, 14). The uncertainty in these measurements is probably near ± 15 K.

$\Delta_{fus} H°$ is calculated from a $\Delta_{fus} S° = 9.5$ cal $K^{-1}\ mol^{-1}$ by multiplication of T_{fus}. $\Delta_{fus} S°$ is assumed the same as that for CaI_2 (3) which also has the hexagonal CdI_2 structure (15). Kelley (16) obtained a value of $\Delta_{fus} H°$ equal to 8.3 kcal mol^{-1} from an analysis of phase diagrams for the systems $MgBr_2$-MBr(M = Na, K) (14) and $MgBr_2$-LiBr (17). However, he implied that the value was somewhat uncertain. Furthermore, it is noted that several $\Delta_{fus} H°$ values listed by Kelley for other alkaline earth dihalides deviate considerably (1-3 kcal mol^{-1}) from those measured calorimetrically (18). Thus, we prefer the estimated value at this time. (See also $MgBr_2(\ell)$ table Enthalpy of Formation Section).

Sublimation Data

See the ideal gas table for details.

PREVIOUS: June 1966 CURRENT: June 1974

MAGNESIUM BROMIDE ($MgBr_2$) LIQUID M_r = 184.113

$S°(298.15\ K)$ = [150.500] J K^{-1} mol^{-1} $\Delta_f H°(298.15\ K)$ = [-490.408] kJ mol^{-1}

T_{fus} = 984 ± 15 K $\Delta_{fus}H°$ = [39.330 ± 4.2] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(984 K)-H°(298.15 K), between the crystal and liquid. The derived value is supported by results obtained from an equilibrium study (1) of the anion exchange reaction 0.5 $MgBr_2(\ell)$ + HCl(g) = 0.5 $MgCl_2(\ell)$ + HBr(g). A third law analysis of the K_p value reported for the equilibrium at 1073 K gives $\Delta_r H°(298.15\ K)$ = 0.05 kcal mol^{-1} which leads to $\Delta_f H°(\ell, 298.15\ K)$ = -117.2 kcal mol^{-1}. In the same paper, Toguri et al. (1) reported similar data for the chloride-bromide salts of Ca, K, and Na. These results lead to $\Delta_f H°(298.15\ K)$ values for the molten bromides which show deviations from adopted JANAF values (2) of no more than 0.6 kcal mol^{-1}. Thus, although the exact agreement in the $\Delta_f H°(298.15\ K)$ values for $MgBr_2(\ell)$ is fortuitous, it does tend to substantiate our thermal data.

Heat Capacity and Entropy

$C_p°$ for the liquid is estimated as 25.0 cal K^{-1} mol^{-1} by analogy with measured $C_p°$ data for molten $CaBr_2$ and $SrBr_2$ (2). The value is taken to be constant above the assumed glass transition at 700 K. Below 700 K, $C_p°$ is that of the crystal.

S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is the temperature at which $\Delta_r G°$ =0 at 1 bar for the process $MgBr_2(\ell)$ = $MgBr_2(g)$. $\Delta_{vap}H°$ is the difference in the enthalpies of formation of the gas and liquid at T_{vap}.

490 (1)

Ground State Quantum Weight: 1 $\sigma = 2$
Point group: $[D_{\infty h}]$
Bond Distance: Mg-Br = 2.34 ± 0.03 Å Bond Angle: Br-Mg-Br = [180]°
Rotational Constant: $B_o = [0.019265]\ cm^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ of the gas is obtained from that of the crystal by addition of $\Delta_{sub}H°(298.15\ K) = 52.9 \pm 2.0\ kcal\ mol^{-1}$ ($221.334 \pm 8.4\ kJ\ mol^{-1}$). The selected value for the enthalpy of sublimation is derived from results of a mass spectrometric-Knudsen effusion study by Berkowitz and Marquart (1). The presence of ~2% dimer in the vapor phase over the solid at near 800 K was revealed by the mass spectral results. Berkowitz and Marquart (1), using $MgBr_2^+$-ion intensity as a measure of the monomer concentration, obtained a 2nd law $\Delta_{sub}H = 50.3\ kcal\ mol^{-1}$ at 751 K. This value when corrected to 298.15 K gives $\Delta_{sub}H°(298.15\ K) = 52.4\ kcal\ mol^{-1}$. Absolute partial pressures were also determined at 798 and 842 K by integrating the ion current during complete volatilization of the sample. A 3rd law analysis of these two pressures gives a enthalpy of sublimation equal to $53.4\ kcal\ mol^{-1}$ which is in good agreement with the value obtained from the ion intensities by the 2nd law. The drift in the 3rd law analysis is $1.0\ cal\ K^{-1}\ mol^{-1}$. The selected value of $\Delta_{sub}H°(298.15\ K)$ is an average of these two results.

Heat Capacity and Entropy

The bond length is from the electron-diffraction measurements of Akishin and Spiridonov (3). Their diffraction patterns for $MgBr_2$ were satisfactorily explained on the basis of a linear model. Klemperer et al. (4, 5) have performed electronic quadrupole deflection experiments on several symmetrical triatomic dihalides in an attempt to determine which molecules possess permanent dipole moments. Their results on the geometrics of the alkaline earth dihalides have been summarized by Hayes (6) who pointed out that the linear form is favored by the light metal-heavy halogen combination. Thus, one would expect $MgBr_2$ to be linear, and we adopt this configuration.

The antisymmetric stretching frequency (ν_3 = 490 cm^{-1}) has been observed in the infrared absorption spectrum of gaseous $MgBr_2$ by Randall et al. (7). The symmetric stretching (ν_1) and bending (ν_2) frequencies are calculated from force constants by the valence force method (8). The observed ν_3 frequency leads to $k = 1.5 \times 10^5$ dynes/cm, or ν_1 = 179 cm^{-1}. A comparison of values for the ratio of the stretch to bend force constants for the linear molecules $MgCl_2$ (9)(ratio = 88)], $CaBr_2$ (9)(ratio = [100])], and $SrBr_2$ (9)(ratio = [100])] suggests a value near 100 for $MgBr_2$. This value for the ratio gives $k\delta/t^2 = 1.5 \times 10^3$ dynes/cm, or ν_2 = 70 cm^{-1}. Based on similar data for linear $BeBr_2$ (10), it is possible that the value of the ratio could be as low as 41. This ratio corresponds to a bending frequency of 109 cm^{-1}. We prefer the lower value of ν_2, since it is consistent with the observed value for $MgCl_2$(9)(ν_2 = 88 cm^{-1})]. However, we do include in the uncertainty of the value for S°(298.15 K) the possibility that the higher value is correct. Brewer et al. (2) used a value for the ratio of 10 and obtained ν_2 = 220 cm^{-1}. By comparison with the observed frequencies for $MgCl_2$ and $BeBr_2$(10)(ν_2 = 220 cm^{-1})] it is unlikely that the value for $MgBr_2$ is this high. Krasnov and Svettsov (11) have reported ν_1 = 188 cm^{-1} and ν_2 = 148 cm^{-1} based on force constant correlations. The ground state is assumed to be singlet by analogy with that for $BaCl_2$ (9).

Enthalpy of Formation

Berkowitz and Marquart (1) have reported the appearance potential of $MgBr_2^+$ as $10.6 \pm 0.1_5$ eV(245.6 kcal mol^{-1}). Assuming this value refers to the direct ionization process $MgBr_2(g) + e^- = MgBr_2^+(g) + 2e^-$, we obtain $\Delta_f H°(MgBr_2^+, g, 0\ K) = 176.7 \pm 6.0$ kcal mol^{-1} by combining the appearance potential with $\Delta_f H°(MgBr_2, g, 0\ K) = -68.9 \pm 2.5$ kcal mol^{-1} (2). The former value corresponds to $\Delta_f H°(298.15\ K) = 174.8$ kcal mol^{-1} (731.363 kJ mol^{-1}) which is adopted.

Heat Capacity and Entropy

A comparison of the dissociation energy, $\Delta_{at}H° = 91.0$ kcal mol^{-1}, for $MgBr_2^+$ with that for $MgBr_2$ (2), $\Delta_{at}H° = 160.3$ kcal mol^{-1}, suggests the existence of somewhat weaker bonding in the ion relative to the molecule. Thus, one would expect the bond length in the ion to be greater than that for $MgBr_2$. We assume a 10% increase in r_e for the ion. The correlation diagrams of Walsh (3) predict a linear configuration for $MgBr_2^+$ (fifteen valence electrons). This prediction is supported by the fact that several other fifteen valence electron molecules (BO_2, N_3, NCO, and NNO^+) are now known to be linear (2). We adopt a linear configuration for the ion.

The vibrational frequencies are estimated to be slightly less than those for $MgBr_2$ (2). The ground state electronic configuration is assumed to be $^2\Pi$ by analogy with those for the isoelectronic molecules (2) BO_2, N_3, NCO, and N_2O^+. Two excited states are also included based on those observed for BO_2 (2). The enthalpy at 0 K is -15.441 kJ mol^{-1}.

MOLYBDENUM BROMIDE ($MoBr_2$) CRYSTAL M_r = 255.748

$S°(298.15\ K) = [124.7 \pm 17]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = unknown

$\Delta_f H°(298.15\ K) = -202.9 \pm 25\ kJ\ mol^{-1}$

Enthalpy of Formation

Shukurov et al. (1)(determined the enthalpies of combustion of $MoBr_2$(cr) and $MoBr_3$(cr). Dellien et al. (2) used the combustion values of Shukurov to obtain $\Delta_f H°(MoBr_2, cr, 298.15\ K) = -54$ kcal mol^{-1} and $\Delta_f H°(MoBr_3, cr, 298.15\ K) = -64$ kcal mol^{-1}. Oppermann (3) carried out equilibrium experiments on the mixed phases $MoBr_2$(cr) + $MoBr_3$(cr). Brewer (4) re-evaluated the data of Oppermann (see the discussion in the $MoBr_4$(g) table (5)) and supplemented the combustion data with other data on $MoBr_4$(cr). For this reason we believe Brewer's value of $\Delta_f H°(MoBr_2, cr, 298.15\ K) = -48.5 \pm 6$ kcal mol^{-1} (-202.924 ± 25 kJ mol^{-1}) to be the most reliable among all the data and is our adopted value. Note that the enthalpy of formation listed in NBS 270-4 (6), $\Delta_f H°(298.15\ K) = -62.4$ kcal mol^{-1}, is much more negative.

Heat Capacity and Entropy

Brewer (4) estimated $S°(298.15\ K) = 29.8 \pm 4$ cal $K^{-1}\ mol^{-1}$ ($124.683 \pm 17\ J\ K^{-1}\ mol^{-1}$) and derived $C_p° = 18.30 + 2.50 \times 10^{-3} T$ cal $K^{-1}\ mol^{-1}$ (298-1353 K) from the heat capacities estimated by Opperman (3). Other estimates are $C_p°(298.15\ K) = 17.1$ cal $K^{-1}\ mol^{-1}$ from the ionic contributions of Kubaschewski and Unal (7) and $S°(298.15\ K) = 30.4$ cal $K^{-1}\ mol^{-1}$ from the additive entropy constants of Stull and Prophet (8). The heat capacity at 298.15 K listed in NBS 270-4 (6) is 18.3 cal $K^{-1}\ mol^{-1}$.

Decomposition Data

T_{dcm} is the calculated temperature at which the pressure of $MoBr_4$(g) is one atmosphere for the reaction 2 $MoBr_2$(cr) = Mo(cr) + $MoBr_4$(g).

Ground State Quantum Weight: I σ = [2]
Point Group: [$D_{\infty h}$]
Bond Distance: Mo-Br = [2.42] Å
Bond Angle: Br-Mo-Br = [180]°
Rotational Constant: B_o = [0.018012] cm^{-1}

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K)$ = 40.0±20 kcal mol^{-1} (167.360±84 kJ mol^{-1}) is that estimated by Brewer (1) using bonding models. The value is consistent with sublimation data for $MoBr_2$ at 1023 K and 1273 K reported by Schafer, et al. (2). Brewer gave no weight to the partial pressures of $MoBr_2$ obtained by Oppermann (3) by difference (see the discussion on the $MoBr_4$(g) table (4)). The value of $\Delta_f H°(0\ K)$ combined with JANAF data (4) for Mo(g) and Br(g) gives $\Delta_{at} H°(MoBr_2, g)$ = 171±20 kcal mol^{-1} (715.5±84 kJ mol^{-1}). This yields a mean bond energy $\Delta_{at} H°(MoBr_2, g)/2$ = 85.5 kcal mol^{-1}, somewhat higher than that found in $MoBr_4$(g), 76.0 kcal mol^{-1} (4)

Heat Capacity and Entropy

The linear structure of $MoBr_2$(g), bond length, and the ground state vibrational frequencies are estimates from Brewer (1). The electronic contributions are assumed to be the same as the free ion, Mo^{++}, as suggested by Brewer (1). All states up to 13,742 cm^{-1} as listed by Rico (5) are included in the calculation.

Enthalpy of Formation

The temperature dependence of the equilibrium constants (1293-1434 K) for the reaction $(NaBr)_2(g) = 2NaBr(g)$ has been studied by Datz et al. (1). The dissociation energy ($\Delta_r E°$(1300 K) was evaluated to be 42.9±1.3 kcal mol^{-1}. The vapor mixture contains 37 to 17% of dimers in the temperature range of 1293 to 1434 K. Hence the vapor pressure data on NaBr(g) reported by the previous investigators were reexamined. In other words, the reported vapor pressures of NaBr(g) is the sum of the partial pressures of both the monomer (NaBr) and the dimer (Na_2Br_2). The partial pressures of $Na_2Br_2(g)$ thus obtained were used to evaluate the enthaply of vaporization by both the 2nd and 3rd law methods. The values of $\Delta_f H°(Na_2Br_2, g, 298.15\ K)$ were then calculated. The results are as follows.

Source	Reaction	$\Delta_r H°$(298.15 K), kcal mol^{-1} 2nd Law	3rd Law	$\Delta_f H°$(298.15 K)* kcal mol^{-1}
Niwa (2)	$2NaBr(cr) + Na_2Br_2(g)$	54.84	56.51	-117.08
Cogin and Kimball (3)	$2NaBr(cr) + Na_2Br_2(g)$	56.69	56.80	-116.01
Mayer and Wintner (4)	$2NaBr(cr) + Na_2Br_2(g)$	68.78	57.13	-115.63**
Ruff and Mugdan (5)	$2NaBr(\ell) + Na_2Br_2(g)$	46.71	45.70	-116.00
Wartenberg and Albrecht (6)	$2NaBr(\ell) + Na_2Br_2(g)$	46.77	45.64	-116.00
Bloom et al. (7)	$2NaBr(\ell) + Na_2Br_2(g)$	51.17	45.49	-116.72**

*Based on the average of the 2nd and 3rd law values.
**Only the third law value being used.

The value of $\Delta_f H°(Na_2Br_2, g, 298.15\ K)$ = -116.24 kcal mol^{-1} (-486.348 kJ mol^{-1}) adopted is the average of the six $\Delta_f H°$(298.15 K) values listed in the above table.

Heat Capacity and Entropy

Bond distance and angles were calculated based on the related data reported by Berkowitz (8). The vibrational frequencies were calculated by Berkowitz (9), from an assumed model. The ground state quantum weight was estimated. The principal moments of inertia are I_A = 19.4713 x 10^{-39}, I_B = 133.0124 x 10^{-39}, and I_C = 152.4836 x 10^{-39} g cm^2.

PREVIOUS: September 1964 (1 atm) CURRENT: September 1964 (1 bar)

$S°(298.15\ K) = 161.13 \pm 2.1\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 644 \pm 5\ K$

$\Delta_f H°(0\ K) = -265.2 \pm 2.5\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -277.4 \pm 2.5\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 16.443 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(PbBr_2, cr, 298.15\ K) = -66.3 \pm 0.6\ kcal\ mol^{-1}$ ($-277.399\ kJ\ mol^{-1}$) is the rounded average of $-66.350\ kcal\ mol^{-1}$ calorimetrically determined by Braune and Koref (1) at about 293.15 K and five other values obtained from a 2nd and 3rd law analysis of electromotive force data (2, 3, 4). The auxiliary value $\Delta_f H°(AgBr, cr, 298.15\ K) = -23.99\ kcal\ mol^{-1}$ (5) is used in the analysis.

Heat Capacity and Entropy

$C°_p$ (18.4 - 297.0 K) has been measured by Latimer and Hoenshel (6). The enthalpy data of Ehrhardt (273-786 K) (7) and of Goodwin and Kalmus (298-860 K) (8) are discarded because the observed high T_{fus} shows their samples were not pure. (See melting data discussion.) Linsey (16) measured the enthalpy (39 points) of $PbBr_2$ in the range 319-424 K using an ice calorimeter. The heat capacity data of Latimer and Hoenshel (6) is smoothed graphically. The enthalpy data was analyzed by Linsey (16) to yield heat capacity values from 273-644 K. Both sets of heat capacity values are adjusted graphically in the region 200-400 K so as to yield a smooth curve in the vicinity of 298 K. The adjustments are quite small such that the resulting enthalpy at 600 K differs by about 7 cal mol^{-1} from the smooth enthalpies reported by Linsey (16). The data of Linsey (16) did not indicate any transitions other than the solid-liquid transition at 644 K.

Latimer and Hoenshel (6) obtained $S°(15.85\ K) = 2.4\ cal\ K^{-1}\ mol^{-1}$ after allowing for an approach to the T^3 rule. Kelley and King (10) later derived $S°(17.80\ K) = 1.64\ cal\ K^{-1}\ mol^{-1}$ from the same data; this value is adopted. Combining this with $S°(298.15;17.80) = 36.871\ cal\ K^{-1}\ mol^{-1}$ derived from the adopted $C°_p$ value gives $S°(298.15\ K) = 38.511 \pm 0.5\ cal\ K^{-1}\ mol^{-1}$ ($161.128\ J\ K^{-1}\ mol^{-1}$). A graphical extrapolation and integration of $C°_p$ gives $H°(17.80;0) = 0.0252\ kcal\ mol^{-1}$. This value may not be entirely consistent with the adopted S°(17.80 K) value, but the error involved is undoubtedly small.

Fusion Data

The older reported values of T_{fus} have been summarized by Mellor (11). Seven determinations fall in the 636-653 K range and four more range from 753 to 772 K. Included in the high melting range are $T_{fus} = 763\ K$ by Ehrhardt (7) and $T_{fus} = 761\ K$ by Goodwin and Kalmus (8). Knowles (12), suggested that contamination of the $PbBr_2$ by PbO probably caused the high melting temperatures. The enthalpy measurements of Ehrhardt (7) and of Goodwin and Kalmus (8) are therefore judged not to represent $PbBr_2$. More recently, Blanc and Petit (13) have reported $T_{fus} = 640\ K$ and $\Delta_{fus}H = 4.96\ kcal\ mol^{-1}$ from a cryoscopic investigation. A visual polytherm technique was employed by Il'yasov (14) who found $T_{fus} = 649\ K$. Cola et al. (15) determined $T_{fus} = 644\ K$ by differential thermal analysis and $\Delta_{fus}H° = 4.41 \pm 0.07\ kcal\ mol^{-1}$ by differential scanning calorimetry. The enthalpy study by Linsey (16) gave $T_{fus} = 644\ K$ and $\Delta_{fus}H° = 3.93\ kcal\ mol^{-1}$ ($16.443\ kJ\ mol^{-1}$). We adopt these latter two values.

Sublimation Data

$\Delta_{sub}H°(298.15\ K) = 41.35\ kcal\ mol^{-1}$ ($173.008\ kJ\ mol^{-1}$) is the sum of the heat of fusion, the enthalpy difference of crystal and liquid between the melting point and 298.15 K, and $\Delta_{vap}H°(298.15\ K)$. See the ideal gas table for details.

LEAD BROMIDE ($PbBr_2$) LIQUID M_r = 367.008

$S°(298.15\ K) = [173.878]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 644 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-267.412]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 16.443 \pm 0.8\ kJ\ mol^{-1}$

Enthaply of Formation

$\Delta_f H°(PbBr_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(644 K)-H°(298.15 K), between the crystal and liquid. $\Delta_f H°(\ell)$ can also be obtained from a 2nd and 3rd law analysis of emf measurements for the cell reaction $Pb(\ell) + Br_2(g) = PbBr_2(\ell)$. Results from three investigations are tabulated below. The auxiliary values, $\Delta_f H°(Pb, \ell, 298.15\ K) = 1.025$ kcal mol^{-1} (1) and $\Delta_f H°(Br_2, g, 298.15\ K) = 7.387$ kcal mol^{-1} (1), are used. The average result or $\Delta_f H°(\ell, 298.15\ K)$ is -63.80 kcal mol^{-1}, in good agreement with the adopted value.

Heat Capacity and Entropy

Ehrhardt (5) and Goodwin and Kalmus (6) have reported enthalpy measurements in the liquid temperature range. Their data are rejected because the high melting points observed indicated the samples were not entirely $PbBr_2$. See the $PbBr_2(cr)$ table discussion. Bizouard and Pauty (7) have measured 26.3±0.6 cal K^{-1} mol^{-1} for the heat capacity of the molten salt. Linsey (9) reported a heat capacity value of 26.8 cal K^{-1} mol^{-1} based on enthalpy measurements from T_{fus} to 924 K. This value is adopted and is assumed to represent the heat capacity up to 2000 K. A glass transition is assumed at 400 K below which the heat capacity is that of the crystal.

$S°(PbBr_2, \ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Vaporization Data

T_{vap} = 1185 K is calculated as the temperature at which $\Delta_r G° = 0$ for the reaction $PbBr_2(\ell) = PbBr_2(g)$ at one atm. $\Delta_{vap} H°$ = 28.23 kcal mol^{-1} (118.114 kJ mol^{-1}) is calculated as the difference between $\Delta_f H°$ at T_{vap} for the gas and the liquid. Bloom and Anthony (8) found an average value of $\Delta_{vap} H° = 29.8 \pm 2.0$ kcal mol^{-1} from mass spectrometric studies in the 660-735 K range. The present table gives $\Delta_{vap} H°(700) = 34.50$ kcal mol^{-1}.

$S°(298.15\ K) = 339.39 \pm 2.9\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -87.99 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -104.39 \pm 6.3\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
208 (1)
64 (1)
189 (1)

Ground State Quantum Weight : [1] $\sigma = 2$
Point Group: C_{2v}
Bond Distance: Pb-Br = 2.6 ± 0.3 Å
Bond Angle: Br-Pb-Br = [95]°
Product of Moments of Inertia: $I_A I_B I_C = [6.47916 \times 10^{-112}]\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K) = -24.95 \pm 1.5$ kcal mol^{-1} (-104.391 kJ mol^{-1}) is the sum of $\Delta_f H°(\ell, 298.15\ K) = -63.913 \pm 0.8$ kcal mol^{-1} and $\Delta_{vap} H°(\ell, 298.15\ K) = 39.96$ kcal mol^{-1}. The adopted enthalpy of vaporization is from the 2nd and 3rd law analyses, tabulated below, of seven sets of liquid vapor pressure measurements, $PbBr_2(\ell) = PbBr_2(g)$. The overall average for $\Delta_{vap} H°(298.15\ K)$ is 39.23 kcal mol^{-1}. The average value of the 3rd law $\Delta_{vap} H°(298.15\ K)$ is 38.96 kcal mol^{-1}. This is in good agreement with both the 2nd and 3rd law values from the data of Wartenberg and Bosse (1). The adopted enthalpy of formation for $PbBr_2(g)$ yields an atomization energy of $\Delta_{at} H° = 5.42$ eV for the process $PbBr_2(g) = Pb(g) + 2\ Br(g)$.

[a] *One point rejected by statistical test.*

Heat Capacity and Entropy

Molecular dimensions are those given by Sutton (8). Beattie and Perry (9) observed the frequencies $\nu_1 = 200\ cm^{-1}$ and $\nu_2 = 64\ cm^{-1}$ in a gas phase Raman study of $PbBr_2$ in the presence of excess bromine; the $PbBr_2$ spectrum was superimposed on the resonance fluorescence spectrum of Br_2. The matrix isolation laser Raman spectroscopic study by Ozin and Vander Voet (10) gave $\nu_1 = 208\ cm^{-1}$ and $\nu_3 = 189\ cm^{-1}$. Experimental conditions prevented observations below 90 cm^{-1} so ν_2 expected about 65 cm^{-1} was *not confirmed. The principal moments of inertia are:* $I_A = 46.2255 \times 10^{-39}$, $I_B = 97.5131 \times 10^{-39}$, *and* $I_C = 143.7386 \times 10^{-39}$ g cm^2.

Point Group: C_{2v} $\sigma = 2$
Bond Distance: Si-Br - [2.19] Å
Bond Angle: Br-Si-Br = 109° ± 3°
Product of the Moments of Inertia: $I_A I_B I_C = [4.91229 \times 10^{-113}]\ g^3\ cm^6$

Enthalpy of Formation

The equilibrium reaction Si(cr) + $SiBr_4$(g) = 2 $SiBr_2$(g) was studied by Schafer et al. (1) and Wolf and Herbst (2). Both investigators used a flow technique in an argon atmosphere. A 2nd and 3rd law analysis of their results (reported only in equation form) is summarized below. As in the case of $SiCl_2$ (3), there is acceptable agreement between these two studies. Using the mean $\Delta_r H°(298.15\ K)$ from the 3rd law results and auxiliary data (3), we calculate and adopt $\Delta_f H°(298.15\ K) = -12.5$ kcal mol^{-1} (52.300 kJ mol^{-1}) for $SiBr_2$(g).

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
Schafer et al. (1)	1320-1475 K	71.61	73.26	1.18
Wolf and Herbst (2)	1200-1550 K	77.33	75.21	-1.54

The adopted enthalpy of formation leads to a $\Delta_{at}H°$ value which implies that the average bond energy is roughly 10% larger in $SiBr_2$(g) than in SiBr(g) or $SiBr_4$(g) (3).

Heat Capacity and Entropy

Maass, Hauge, and Margrave (4) observed the infrared spectra of $SiBr_2$ in nitrogen and argon matrices in the Si-Br stretching region. Attempts to observe the bending fundamental in the region between 90 cm^{-1} and 150 cm^{-1} were unsuccessful. Maass et al. (4) measured and assigned ν_1 and ν_3. The bond angle was calculated to be 109±3° from the isotopic splittings due to three silicon isotopes. The authors also assumed ν_2 = 120 cm^{-1}. This bending frequency is consistent with the analogous $SiBr_2$ "bending mode" in SiH_2Br_2 (3). We adopt the frequencies and bond angles as suggested by Maass et al. (4).

We assume the Si-Br bond distance to be the same as that in SiH_2Br_2 (3). By observing the trends in SiF_2 and $SiCl_2$ (3), we assume a $^1A_1$ ground electronic state and a $^3B_1$ excited state at ~20000 cm^{-1}. Additional support for this assignment comes from the luminescense spectrum of a glow discharge in $SiBr_4$ vapors observed by Kuznetsova and Kuzyokov (5). They states that the complex spectral structure of the 16800-23500 cm^{-1} band could be attributed to the oscillation and deformation of the nonlinear $SiBr_2$ molecule. The inclusion of this triplet electronic state increases the entropy by 0.0004 cal K^{-1} mol^{-1} at 3000K. The principal moments of inertia are: $I_A = 6.4154 \times 10^{-39}$, $I_B = 84.3558 \times 10^{-39}$, and $I_C = 90.7711 \times 10^{-39}$ g cm^2.

STRONTIUM BROMIDE ($SrBr_2$) CRYSTAL M_r = 247.428

$S°(298.15\ K) = 143.4 \pm 4.2\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 918\ K$
$T_{fus} = 930\ K$

$\Delta_f H°(0\ K) = -704.96 \pm 1.7\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -717.97 \pm 1.7\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 12.217 \pm 0.21\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 10.125 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

The selected value for $\Delta_f H°$ is derived from results of solution calorimetric measurements in aqueous acids performed by Ehrlich et al. (1). Their results on the enthalpy of solution of Sr(cr) and $SrBr_2$(cr) in $HBr \cdot 555\ H_2O$ are combined with data for HBr(aq) (2, 3) *in a thermochemical cycle to give* $\Delta_f H°(SrBr_2, cr, 298.15\ K) = -171.6 \pm 0.4$ kcal mol^{-1} (-717.974 ± 1.7 kJ mol^{-1}). In the same paper, Ehrlich et al. (1) reported similar results for three (Ca, Sr, and Ba) of the alkaline earth dichlorides; these results have been the basis for adopted JANAF enthalpies of formation (4) for these dichlorides.

Independent values for $\Delta_f H°$ *can be obtained from measurements of the enthalpy of solution of* $SrBr_2$*(cr) in aqueous solution* (5-7) as summarized by Bichowsky and Rossini (8). Combining these results with $\Delta_f H°(Sr^{+2}, \infty\ aq, 298.15\ K) = -130.45$ kcal mol^{-1} (9) and $\Delta_f H°(Br^-, \infty\ aq, 298.15\ K) = -29.039 \pm 0.036$ kcal mol^{-1} (2), we derive $\Delta_f H°$ values for $SrBr_2$(cr) in kcal mol^{-1} of -171.5 (5), -172.2 (6), and -171.6 (7). Deviations from our adopted value are at worst only 0.6 kcal mol^{-1}, and the results of two studies (5, 7) provide additional support for the selected value of $\Delta_f H°$. Also, our value for $\Delta_f H°$ is essentially that (-171.5 kcal mol^{-1}) selected by NBS (9).

Heat Capacity and Entropy

$C_p°$ data below 300 K are based primarily on the adiabatic calorimetry (60-302 K) of Taylor and Smith (10]. These $C_p°$ data *show an unusual leveling off at near 18.0 cal* K^{-1} mol^{-1} *above 245 K. We adopt their* $C_p°$ *data in the temperature range 60-245 K;* values above 245 K are estimated by comparison with similar data for $SrCl_2$ and $BaCl_2$ (4]. Our value for $C_p°$ at 298.15 K (18.37 cal K^{-1} mol^{-1}) is roughly 0.4 cal K^{-1} mol^{-1} higher than the measured value of Taylor and Smith (10]. Huttig and Slonim (11] have reported mean heat capacity values over three temperature intervals *(85-198, 196-271,* and *276-368 K). Their measurements* suggest a slightly higher value (18.8 cal K^{-1} mol^{-1}) for $C_p°$ at 298.15 K than is adopted.

Taylor and Smith (10] reported S°(298.15 K) = 32.29 cal K^{-1} mol^{-1} based on S°(60 K) = 6.68 cal K^{-1} mol^{-1} obtained from Debye-Einstein functions which represented their $C_p°$ data to only ±1.8 percent from 60 to 100 K. A comparison of their extrapolated $C_p°$ data with those which have been measured for $SrCl_2$, $BaCl_2$, and CaI_2 (4] indicates that the values for $SrBr_2$ decrease much more rapidly with temperature below 50 K than would be expected. We have made our own extrapolation to 0 K for $SrBr_2$ by comparison with the measured data for $SrCl_2$ (7.4 to 60 K), $BaCl_2$(6 to 60 K), and CaI (13.1 to 60 K). Our extrapolation gives S°(60 K) = 8.7 cal K^{-1} mol^{-1}, or S°(298.15 K) = 34.28 cal K^{-1} mol^{-1} (143.438 J $K^{-1}mol^{-1}$) based on the adopted $C_p°$ data (60-300 K). Our value for S°(298.15 K) is consistent with the estimates of 35 cal K^{-1} mol^{-1} (12] and 33.8 cal K^{-1} mol^{-1}(13], suggesting a possible uncertainty of ±1 cal K^{-1} mol^{-1} in the adopted value.

Taylor and Smith (10] measured relative enthalpy data (293-902 K) on a portion of the same sample used for their $C_p°$ measurements. This sample was reported to contain less than 0.1% oxide and was investigated in a Bunsen ice calorimeter. Our analysis of their relative enthalpies by curve fitting techniques reveals the existence of considerable scatter in the data, and no weight is given to their results. The average deviation of 36 points in a Shomate type fit is 2.5%; the maximum deviation is -9.3% at 397 K. Also, these workers (10] were apparently unaware of the transition in $SrBr_2$ at 918 K, since their data set contains only two enthalpy points between 902-927 K. Relative enthalpies have also been measured by Dworkin and Bredig (14], and the results were reported in graphical form. The short temperature interval (846-902 K) over which these measurements were made for the α phase preclude derivation of accurate heat capacities. Dworkin and Bredig (14) also reported in the same paper enthalpy data for three (Ca, Sr, and Ba) of the alkaline earth dichlorides. A comparison of these enthalpies with those adopted by JANAF (4) indicates that their results are probably reliable to better than ±2%. We adopt their measured value *for* H°(918;298.15) = 12.37 *kcal* mol^{-1} *of the α phase at the transition temperature.* $C_p°$ *values (300-918 K)* are then estimated by comparison with those for $SrCl_2$ and $BaCl_2$ (4). These estimates are made so as to reproduce as closely as possible the adopted enthalpy at 918 K. Our estimated $C_p°$ data give a value of H°(918;298.15) = 12.35 kcal mol^{-1} which agrees with the *measured value of Dworkin and Bredig to within 20 calories. The enthalpies of Taylor and Smith (10) are roughly 2.5% higher* than the adopted values at temperatures near the transition. $C_p°$ data for the β phase (918-930 K) are taken from Dworkin and Bredig (14) and extrapolated above the melting point.

Transition Data

Existence of two forms of $SrBr_2$ has been shown by thermal analysis (15-18) and drop calorimetry (14). Values of T_{trs} reported are 915 K (15-16), 920 K (17), 919 K (18), and 918 K (14). We adopt the last value which is based on the drop calorimetry of Dworkin and Bredig (14). Several other investigators (10, 19-21) have mistakenly interpreted the transition as due to melting.

$\Delta_{trs} H°$ of 2.92 kcal mol^{-1} (12.217 kJ mol^{-1}) is derived from the enthalpy data of Dworkin and Bredig (14).

Fusion Data

See the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ is calculated as the difference in the adopted gas and crystal enthalpies of formation at 298.15 K.

STRONTIUM BROMIDE ($SrBr_2$) LIQUID M_r = 247.428

$S°(298.15\ K) = [154.843]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} \approx 930\ K$

$\Delta_f H°(298.15\ K) = [-705.098]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 10.125 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(SrBr_2, \ell)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(930\ K) - H°(298.15\ K)$, betweeen the crystal and liquid.

Heat Capacity and Entropy

$C°_p$ for the liquid in the temperature range 600-3000 K is assumed constant at 27.818 cal $K^{-1}\ mol^{-1}$. This value is based on JANAF curve fits (deviations ± 0.1%) of the relative enthalpies (931-1002 K) reported by Dworkin and Bredig (1). Taylor and Smith (2) have also reported enthalpies (927-1118 K) for the liquid. These results suggest a somewhat higher value (28.36 cal $K^{-1}\ mol^{-1}$) for $C°_p$; however, the data are considered less reliable. (See $SrBr_2$(cr) table for further discussion). The average deviation of the data of Taylor and Smith (2) from our adopted enthalpies is ±0.4%; the maximum deviation is 1.2% at 1067 K. A glass transition is assumed at 600 K below which $C°_p$ is that of the crystal.

$S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} is that observed by Dworkin and Bredig (1) from drop calorimetry. Other reported values for T_{fus} are 926 K (3), 931 K (4), 924 K (5), and 928 K (6). Four other investigators (2, 7-10) have reported values of T_{fus} near 916 K, but they have mistakenly interpreted the transition in $SrBr_2$ as that due to melting.

$\Delta_{fus} H°$ is calculated as the difference in the enthalpies of the liquid and β phase at T_{fus}. The enthalpy of the liquid at T_{fus} is based on JANAF curve fits of the enthalpy data reported by Dworkin and Bredig (1). We adopted their measured value of 15.6 kcal mol^{-1} for $H°(930;298.15)$ of the β phase at T_{fus}. A cryoscopic (4) determination of $\Delta_{fus} H°$ gave 2.6±1.3 kcal mol^{-1} which agrees well with the adopted calorimetric value. Taylor and Smith (2) reported a calorimetric value of $\Delta_{fus} H° = 5.25$ kcal mol^{-1}; however, this value also includes the heat of transition. Addition of our values for $\Delta_{trs} H°$ and $\Delta_{vap} H°$ gives 5.34 kcal mol^{-1}.

Vaporization Data

T_{vap} is the temperature at which $\Delta_r G°$ for the process $SrBr_2(\ell) = SrBr_2(g)$ approaches zero. $\Delta_{vap} H°$ is the difference in the heats of formation of the gas and liquid at T_{vap}. Peterson and Hutchinson (10) obtained T_{vap} = 2318 K from vapor pressure measurements on the liquid (1114-1304 K). However, the value is based on a rather long extrapolation and is probably uncertain to at least ± 100 K.

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Sr-Br = 2.82 ± 0.03 Å

Bond Angle: Br-Sr-Br = 180°

Rotational Constant: $B_0 = 0.013265\ cm^{-1}$

Enthalpy of Formation

Peterson and Hutchison (1, 2) have measured vapor pressures (1114-1304 K) for liquid $SrBr_2$ by the Knudsen effusion method. Results of 2nd and 3rd law analysis of these pressures are tabulated below. We assume that the dibromide monomer was the only vapor species present. Mass spectra for some of the other alkaline earth dihalides (3) indicate that the saturated vapor consist predominantly of the metal dihalide monomer which agrees with predictions which were made by Brewer et al. (4) for the dihalide molecules. Included in the table is a value for $\Delta_f H°$ derived from a 3rd law analysis of a single vapor pressure point determined by Stock and Heynemann (5) and tabulated by Brewer et al. (4).

Source	Reaction[a]	Data Points	T/K	Δ H°(298.15 K), kcal mol⁻¹ 2nd law	3rd law	Drift cal K⁻¹ mol⁻¹	$\Delta_f H°$(298.15 K) kcal mol⁻¹
(1, 2)	A	13[a]	1147-1304	69.9	71.24±0.86	1.1±2.5	97.3±2.5
(4, 5)	A	1	1040		66.9		101.6

[a]Reaction: (A) $SrBr_2(\ell) = SrBr_2(g)$; [b]Two points rejected due to failure of a statistical test.

The value $\Delta_f H°(SrBr_2, g, 298.15\ K) = -97.3 \pm 3.0$ kcal mol^{-1} (-407.103±12.6 kJ mol^{-1}) is preferred here rather than an average (-99.5 kcal mol^{-1}) of the two results, since it is impossible to assess the reliability of the measurement by Stock and Heynemann (5). However, our value does compare favorably with that (-98.0 kcal mol^{-1}) selected by NBS (6).

Heat Capacity and Entropy

The value of the bond length is that measured by Akishin and Spiridonov (7) in a high-temperature electron diffraction study. Electron diffraction patterns (7) for $SrBr_2$ were satisfactorily explained on the basis of a linear model (180° ± 10°). Later studies by Wharton et al. (8), using electric deflection of molecular beams to detect dipole moments, showed no polarity in the $SrBr_2$ molecule; this is most reasonably explained by a linear and centrosymmetric configuration.

Few infrared spectral studies (9-11) have been reported for the gaseous alkaline earth dibromides. The antisymmetric stretch (ν_3) and bending (ν_2) frequencies for $BeBr_2$ were observed by Snelson (9) in a neon matrix. Baikov (10) observed a band at 330±5 cm^{-1} in the high-temperature infrared spectra of $CaBr_2$ vapor and assigned this band to ν_3. In a similar study on $MgBr_2(g)$ by Randall et al. (11) ν_3 was observed at 490 cm^{-1}. The only frequencies available for $SrBr_2$ are estimates (4, 10, and 12) which have been obtained by force constant calculations. The adopted vibrational frequencies are derived from force constants estimated by the valence force method (13). A comparison of values for the ratio of the stretching force constants for diatomic and triatomic strontium fluorides (ratio = 1.33, 3) and chlorides (ratio = 1.15, 3) suggests a value of near unity for the ratio of the bromides. Therefore, the stretching force constant for $SrBr_2$ is taken equal to that for SrBr(k = 1.154 x 10^5 dynes/cm) (4). Our values for ν_1 and ν_3 compare favorably with those estimated by a similar procedure (4) (ν_1 = 156 cm^{-1} and ν_3 = 262 cm^{-1}) and with those given by Krasnov and Svettsov (12, ν_1 = 158 cm^{-1} and ν_3 = 265 cm^{-1}). The estimated frequencies of Baikov (10) are roughly 12% lower than ours. A comparison of values for the ratio of the stretch to bend force constants for the bent molecules SrF_2(ratio = 50, 3) and $SrCl_2$(ratio = 78, 3) suggests a value near 100 for $SrBr_2$. Brewer (4) used this same value in his force constant calculations. This value for the ratio gives $k\delta'/\ell^2$ = 1.154 x 10^3 dynes/cm, or ν_2 = 37 cm^{-1}. A comparison of similar data for the linear molecule $BeBr_2$ (9) indicates that the value of the ratio could be as low as 41. This leads to a ν_2 = 58 cm^{-1} which is in excellent agreement with the value (56 cm^{-1}) recommended by Krasnov and Svettsov (12). We prefer the lower value of ν_2 at this time but include in the uncertainty ±2.0 cal K^{-1} mol^{-1} assigned to the value of S°(298.15 K) the possibility that the higher value is the correct one. The singlet ground state is assigned by analogy with that for $BaCl_2$ (3). Our adopted functions agree with those tabulated by Brewer et al. (4) to within 0.1 cal K^{-1} mol^{-1} in the range 298-2000 K.

PREVIOUS: June 1974 (1 atm) CURRENT: June 1974 (1 bar)

TITANIUM BROMIDE ($TiBr_2$) CRYSTAL M_r = 207.688

$S°(298.15\ K) = [108.4 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = unknown

$\Delta_f H°(298.15\ K) = -405.43 \pm 20.9\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of $TiBr_2$ crystal is derived from the data of Hall and Blocher (1) for the reaction 2 $TiBr_3$(cr) = $TiBr_4$(g) + $TiBr_2$(cr). 2nd and 3rd law analyses of these data are not useful because of the formation of solid solutions in the above process. Hall and Blocher (1) obtained a value of $\Delta_r H°(800\ K)$ of 31.3 kcal mol^{-1} for the reaction by integrating the incremental Gibbs energy changes over varying compositions of the solid solutions. The corresponding $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(298.15\ K)$ are calculated as 34.6 kcal mol^{-1} and -96.9 kcal mol^{-1} (-405.430 kJ mol^{-1}), respectively, using auxiliary JANAF enthalpy of formation and enthalpy data.

Heat Capacity and Entropy

The heat capacity of $TiBr_2$(cr) was estimated by Kelley (2). The value of $S°(298.15\ K)$ is estimated from that of $TiCl_2$(cr) and the difference between ionic entropy contribution of Cl^- and Br^-.

Sublimation Data

The enthalpy sublimation of $TiBr_2$(cr) is taken as the difference in the enthalpies of formation of $TiBr_2$(cr) and $TiBr_2$(g) at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta_r G° = 0$ for the reaction $TiBr_2$(cr) $TiBr_2$(g). The enthalpy of formation of $TiBr_2$(g), upon which these quantities depend, is an estimated quantity.

Bond Angle: Br-Ti-Br = [180°]
Rotational Constant: B_0 = [0.018314] cm^{-1}

Enthalpy of Formation

The enthalpy of formation of $TiBr_2(g)$ is calculated from the estimated Ti-Br bond energy. The bond energy is estimated as being the same as the average Ti-Cl bond energy of $TiCl_2(g)$. This estimate is used because the measured average bond energies of $TiBr_3(g)$ and $TiCl_3(g)$ and those of $TiBr_4(g)$ and $TiCl_4(g)$ are very nearly equal.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2(g)$, $TiCl_4(g)$ and $TiBr_4(g)$. The vibrational frequencies are estimated from a valence force field model. The force constant k is estimated as 1.2 millidynes $Å^{-1}$, and the constant k_δ/ℓ^2 is assumed to be 0.06 millidynes $Å^{-1}$. These values are derived by a correlation with other dihalides.

The electronic levels are assumed to be the same as $TiCl_2(g)$. The levels of $TiCl_2(g)$ are estimated by assuming that they correspond to the inverted states of $NiCl_2(g)$ (1). The linear configuration is adopted since experimental evidence indicates that other transition metal dihalides are linear (2, 3, 4, 5).

PREVIOUS: June 1968 (1 atm) CURRENT: June 1968 (1 bar)

ZIRCONIUM BROMIDE ($ZrBr_2$) CRYSTAL M_r = 251.028

$S°(298.15\ K)$ = [115.9 ± 13] J K^{-1} mol^{-1}
T_{fus} = [900] K

$\Delta_f H°(0\ K)$ = unknown
$\Delta_f H°(298.15\ K)$ = [-404.6 ± 42] kJ mol^{-1}
$\Delta_{fus} H°$ = [62.760 ± 42] kJ mol^{-1}

Enthalpy of Formation

The value of $\Delta_f H°(ZrBr_2, cr, 298.15\ K)$ = -96.7 kcal mol^{-1} (-404.593 kJ mol^{-1}) is calculated from the estimated $\Delta_{sub} H°(298.15\ K)$ = 55±5 kcal mol^{-1} for $ZrBr_2(cr) + ZrBr_2(g)$, using $\Delta_f H°(ZrBr_2, g, 298.15\ K)$ = -41.7 kcal mol^{-1} (1). The estimated $\Delta_{sub} H°(298.15\ K)$ is obtained as an average of the enthalpies of sublimation at 298°K for $CrBr_2$, $MnBr_2$, $CoBr_2$ and $NiBr_2$ given by Brewer, Somayajulu and Brackett (2) and $TiBr_2$ and $FeBr_2$ listed in JANAF tables (1).

Heat Capacity and Entropy

The heat capacities of $ZrBr_2(cr)$ are estimated from $TiBr_2(cr)$ (1), based on the assumption $C_p°(ZrBr_2) = C_p°(TiBr_2) + 3/2\ R\ln[A_r \text{ of Zr})/(A_r \text{ of Ti})]$. The entropy, $S°(298.15\ K)$ = 27.7 cal K^{-1} mol^{-1} (115.897 J K^{-1} mol^{-1}) is estimated in a similar manner based on $TiCl_2(cr)$ (1) and $TiBr_2(cr)$ (1).

Fusion Data

The enthalpy of fusion is roughly estimated, so that the entropy of vaporization is about 20 cal K^{-1} mol^{-1}. The melting point was estimated by Brewer (3).

PREVIOUS: March 1962 CURRENT: June 1970

ZIRCONIUM BROMIDE ($ZrBr_2$) LIQUID M_r = 251.028

$S°(298.15\ K)$ = [184.024] J K^{-1} mol^{-1}

T_{fus} = [900] K

$\Delta_f H°(298.15\ K)$ = [-342.333] kJ mol^{-1}

$\Delta_{fus} H°$ = [62.760 ± 42] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(ZrBr_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(900 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be constant at 7.25 cal K^{-1} g-atom^{-1}. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change approaches zero for the process $ZrBr_2(\ell) \rightarrow ZrBr_2(g)$ at one bar. The difference between $\Delta_f H°$ for $ZrBr(\ell)$ and $ZrBr_2(g)$ at T_{vap} is $\Delta_{vap} H°$.

Rotational Constant: B_0 = [0.017290] cm^{-1}

Enthalpy of Formation

$\Delta_f H°(ZrBr_2, g, 298.15\ K) = -41.7\ kcal\ mol^{-1}$ ($-174.473\ kJ\ mol^{-1}$) is derived from the estimated $\Delta_r H°(298.15\ K) = 243.5 \pm 10\ kcal\ mol^{-1}$ for $ZrBr_2(g) \rightarrow Zr(g) + 2\ Br(g)$. The value of $\Delta_r H°(298.15\ K)$ is twice the average bond dissociation energy, $\Delta_{at} H°(298.15\ K)/2 = 121.75\ kcal\ mol^{-1}$, which is calculated from the proportion of the average bond dissociation energies at 298.15 K for $ZrBr_2/TiBr_2 = ZrBr_4/TiBr_4$. The average bond dissociation energies at 298.15 K, $\Delta_{at} H°(ZrBr_4)/_4 = 102.2\ kcal\ mol^{-1}$, $\Delta_{at} H°(TiBr_4)/_4 = 87.9\ kcal\ mol^{-1}$, and $\Delta_{at} H°(TiBr_2)/_2 = 104.6\ kcal\ mol^{-1}$, are all calculated from JANAF $\Delta_f H°(298.15\ K)$ for $ZrBr_4(g)$, $TiBr_4(g)$, $TiBr_2(g)$, Zr(g), Ti(g), and Br(g).

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that the transition metal dihalides are generally linear (1, 2, 3, 4, 5) even though a few fluorides are bent (6). The bond distance is assumed to be the same as that in $ZrBr_4(g)$ which was estimated as 2.47 Å by Godnev et al. (7).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 1.2 millidyne $Å^{-1}$ and the bending force constant 0.06 millidyne $Å^{-1}$. These values are derived from force constants of transition metal dihalides listed by Brewer, Somayajulu and Brackett (8). The electronic levels and quantum weights are estimated to be the same as those of gaseous $TiCl_2$ (9).

Bond Angles: H-Si-Br = 107.51° Br-Si-Br = 111.36°
Product of the Moments of Inertia: $I_A I_B I_C = 1.31228 \times 10^{-11}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated by linear interpolation between the values (1) of $SiBr_4(g)$ and $SiH_4(g)$. In adopting linear estimate for SiH_nBr_{4-n} (n=1,2,3), we dismiss the solution calorimetry of Wolf et al. (2) because of possible negative bias. These authors reported $\Delta_f H(g, 298.15\ K) = -69.3 \pm 2.0$ kcal mol^{-1} derived from enthalpies of solution in dilute aqueous NaOH. Wagman et al. (3) changed this value to -75.9 kcal mol^{-1} due to revised auxiliary data, especially $\Delta_f H°$ of $Na_2SiO_3(cr)$ and $Na_2SiO_5(sln)$. The calorimetric result is 3.5 kcal mol^{-1} more negative than our linear estimate. This could imply a cubic variation of $\Delta_f H°(SiH_nBr_{4-n})$ with n, such as we adopt for the chlorosilanes (1). We tentatively reject this hypothesis because the solution results (2) for $SiHCl_3(g)$, $SiCl_4(g)$, $SiBr_4(\ell)$ and $SiI_4(cr)$ are also more negative than our adopted values (1). It is conceivable that the hydrolysis reactions did not proceed to equal degrees in the different calorimetric studies. We conclude, as did Hunt and Sirtl (4), that the available data justify only linear interpolation of $\Delta_f H°$.

Heat Capacity and Entropy

The molecular structure is based on microwave data of Mitzlaff et al. (5) for eight isotopic forms of $SiHBr_3$ and $SiDBr_3$. Structural parameters are presumably substitutional (r_s) values. The principal moments of inertia are: $I_A = I_B = 87.7371 \times 10^{-39}$ and $I_C = 170.4749 \times 10^{-39}$ g cm^2. Vibrational frequencies are from gas-phase infrared spectra of Buerger and Cichon (6). Assignments are based on band contour analysis and are consistent with Shimanouchi's values (7) derived from liquid-phase Raman spectra (8).

We neglect excited states and assume the electronic ground state to be a singlet. We expect that contributions from excited states should be unimportant, as discussed on the tables for SiH_3Br and SiH_2Cl_2 (1).

PREVIOUS December 1976 (1 atm) CURRENT December 1976 (1 bar)

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

$S°(298.15\ K) = [174.5 \pm 17]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = unknown

$\Delta_f H°(298.15\ K) = -283.7 \pm 25\ kJ\ mol^{-1}$

Enthalpy of Formation

Shukurov et al. (1) determined the enthalpy of combustion of $MoBr_3$(cr). Dellien et al. (2) obtained $\Delta_f H°(298.15\ K)$ = -64±5 kcal mol^{-1} from the calorimetric result. Brewer (3) re-examined the equilibrium measurements of Oppermann (4) on the mixed solids $MoBr_2$ + $MoBr_3$ (see the discussion on the $MoBr_4$(g) table (5)) and obtained $\Delta_f H°(298.15\ K)$ = -67.8±6 kcal mol^{1} (-283.675±25 kJ mol^{-1}) which is the value adopted here.

Heat Capacity and Entropy

Brewer (3) estimated $S°(298.15\ K)$ = 41.7±4 cal K^{-1} mol^{-1} (174.473±17 J K^{-1} mol^{-1}) and derived $C_p° = 24.14 + 3.50 \times 10^{-3}T$ cal K^{-1} mol^{-1} (298-963 K) from the heat capacities estimated by Opperman (4). Other estimates are $S°(298.15\ K)$ = 40.9 cal K^{-1} mol^{-1} from the additive entropy constants of Stull and Prophet (6) and $C_p°(298.15\ K)$ = 23.3 cal K^{-1} mol^{-1} from the ionic contributions of Kubaschewski and Unal (7). We adopt the estimates of Brewer (3).

Decomposition Data

T_{dcm} *is the calculated temperature at which* $\Delta_r G° = 0$ *for the reaction* 2 $MoBr_3$(cr) = $MoBr_2$(cr) + $MoBr_4$(g) at one bar.

Point Group: [D_{3h}] σ = [6]
Bond Distance: Mo-Br = [2.42] Å
Bond Angle: Br-Mo-Br = [120]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [3.16715 x 10^{-111}] g^3 cm^6

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K)$ = -2.0±8 kcal mol^{-1} (-8.368±33 kJ mol^{-1}) is that estimated by Brewer (1) who used bonding models to estimate the enthalpy of formation of MoBr(g), $MoBr_2$(g), and $MoBr_3$(g). The value of $\Delta_f H°(0\ K)$ combined with JANAF data (2) for Mo(g) and Br(g) leads to $\Delta_{at}H°(MoBr_3, g)$ = 238.6±8 kcal mol^{-1}. The mean bond energy $\Delta_{at}H°(MoBr_3, g)/3$ = 79.5±3 kcal mol^{-1} compared to $\Delta_{at}H°(MoBr_4, g)/4$ = 76.0 kcal mol^{-1} (4). The enthalpy of formation of $MoBr_4$(g) is based on the experimental measurements of Oppermann (3), providing some confidence in the estimate of Brewer.

Heat Capacity and Entropy

Brewer (1) used a slight modification of the vibrational frequencies and internuclear distance estimated by Lofgren (4). The Mo-Br distance was taken as 2.42 Å. Drake and Rosenblatt (5) predicted that $MoBr_3$ would be planar. The electronic contributions are taken to be the same as those for MoF_3(g) (2) which are estimated from TaO(g) (2). The principal moments of inertia are $I_A = I_B$ = 116.5591 x 10^{-39} g cm^2 and I_C = 233.1183 x 10^{-39} g cm^2

PHOSPHORYL BROMIDE ($POBr_3$) IDEAL GAS M_r = 286.68516

$S°(298.15\ K) = 359.83\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-379.4]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [-406.0]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
118 (2)	340 (1)
173 (1)	488 (2)
267 (2)	1261 (1)

Ground State Quantum Weight: [1] $\sigma = 3$
Point Group: C_{3v}
Bond Distances: P-O = 1.41 ± 0.07 Å P-Br = 2.06 ± 0.03 Å
Bond Angle: Br-P-Br = 108° ± 3°
Product of the Moments of Inertia: $I_A I_B I_C = 1.11121 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

The $\Delta_f H°(POBr_3, g, 298.15\ K)$ is calculated from the enthalpy of formation of the crystal and the enthalpy of sublimation. The enthalpy of sublimation is obtained by combining the $\Delta_{vap}H°$ and an estimated $\Delta_{fus}H°$. The enthalpy of formation of the crystal is derived from the enthalpies observed for the reaction: $POBr_3(cr) + (n+3)H_2O(\ell) \rightarrow [H_3PO_4 + 3\ HBr]\ in\ nH_2O(\ell)$. The data used in these calculations may be summarized as follows:

Data	Source
$\Delta_f H°(H_3PO_4, aq, 298.15\ K)$	Obtained graphically from Holmes (1)
$\Delta_f H°(HBr, aq, 298.15\ K)$	Obtained graphically from (2)
$\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.3174\ kcal\ mol^{-1}$	Obtained from (2)
$\Delta_f H°(POBr_3, cr, 298.15\ K) = -109.1\ kcal\ mol^{-1}$	Recalculated from data of Charnley and Skinner (3)
$\Delta_{fus}H°(298.15\ K) = [3.7]\ kcal\ mol^{-1}$	Estimated from comparison with $POCl_3$
$\Delta_{vap}H°(298.15\ K) = [12.1]\ kcal\ mol^{-1}$	Estimated from the $\Delta_{vap}H°$ at T_{vap}(10.6 kcal mol^{-1} at 464.9 K). $\Delta_{vap}H$ was calculated from a least squares treatment of the vapor pressure data of Driel (4)

Heat Capacity and Entropy

The molecular constants used were calculated from electron diffraction measurements by Secrist and Brockway (5). The principal moments of inertia are: $I_A = I_B = 86.8222 \times 10^{-39}\ g\ cm^2$ and $I_C = 147.4125 \times 10^{-39}\ g\ cm^2$.

From the Raman spectra of $POBr_3$ the vibrational frequencies were measured and assigned by Gerding and Driel (6). The Raman spectra was studied and the vibrational frequencies were listed by Delwaulle and Francois (7).

PHOSPHORUS BROMIDE (PBr_3) IDEAL GAS M_r = 270.68576

$S°(298.15\ K) = 348.234\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -121.7 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -146.0 \pm 6.3\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
392 (1)	392.2 (2)
161.3 (1)	115.7 (2)

Ground State Quantum Weight: [1] $\sigma = 3$
Point Group: C_{3v}
Bond Distance: P-Br = 2.20 ± 0.03 Å
Bond Angle: Br-P-Br = 106° ± 3°
Product of the Moments of Inertia: $I_A I_B I_C = 1.18987 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation of PBr gas from white (α) phosphorus, -34.9 kcal mol^{-1}, was obtained by Charnley and Skinner (1). To obtain their value (-34.9 kcal mol^{-1}), Charnley and Skinner (1) measured the enthalpy of formation of the liquid, and combined it and their estimate of the liquid enthalpy with the enthalpy of vaporization (9.5 kcal mol^{-1}) calculated by Driel and Gerding (2). For the liquid enthalpy of formation Charnley and Skinner (1) observed the $\Delta_r H°$ = -67.2±0.6 kcal mol^{-1} for $PBr_3(\ell) + (n+3)H_2O(\ell) + [H_3PO_3 + 3HBr]$ in $nH_2O(\ell)$. Driel and Gerding (2) measured the vapor pressure over $PBr_3(\ell)$ and calculated the enthalpy of vaporization with the aid of a modified Claperyron equation. The uncertainties on the enthalpy of formation are estimates.

Heat Capacity and Entropy

Williams and Gordy (3) have reported moments of inertia from the microwave spectrum of PBr_3. From this data Whiffen (4) has calculated the selected molecular constants. The principal moments of inertia are: $I_A = I_B = 85.2188 \times 10^{-39}\ g\ cm^2$ and $I_C = 163.8427 \times 10^{-39}\ g\ cm^2$.

Lister and Sutton (5) have reported P-Br = 2.23 ± 0.04 Å and the angle Br-P-Br = 100±2. Swingle (6) has measured P-Br = 2.18±0.03 Å and the angle Br-P-Br = 101.5±1.5. Swingle's data as well as that of Lister and Sutton were obtained by electron diffraction. The 106° angle was selected since 101.5° and 100° give imaginary force constants with the ranges allowed for the type A, 392 cm^{-1} frequency and the form of the potential function assumed by Davis and Oetjen (7).

The vibrational frequencies were measured and assigned in the infrared by Davis and Oetjen (7). Raman measurements and assignments by Cabannes and Rausset (8) were also listed by Delwaulle (9). The Raman assignments were as follows: type A, 380 cm^{-1} and 162 cm^{-1} and type E, 400 cm^{-1} and 116 cm^{-1}.

Ground State Quantum Weight: [1] $\sigma = 3$

Point Group: C_{3v}

Bond Distance: P-Br = 2.13 ± 0.03 Å P-S = 1.89 ± 0.06 Å

Bond Angle: Br-P-Br = 106° ± 3°

Product of the Moments of Inertia: $I_A I_B I_C = 1.94531 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

The $\Delta_f H°(PSBr_3, g, 298.15\ K)$ was calculated from the $\Delta_f H°(POBr_3, g, 298.15\ K)$ *and estimated strengths* for P-S and P-O bonds.

The difference in the P-S and P-O bond strengths was assumed to be the same for POF_3 - PSF_3 and $POBr_3$ - $PSBr_3$. For the P-S bond strength in PSF_3, Henderson and Scheffee (1) estimated 91 kcal from a consideration of *unpublished data*. The P-O bond was estimated to be 115 kcal by Neale and Williams (2) and Neale et al. (3).

Auxiliary data for $POBr_3(g)$, O(g), and S(g) are from the JANAF tables (4).

Heat Capacity and Entropy

The molecular constants were determined from electron diffraction data by Secrist and Brockway (5). The principal moments of inertia are: $I_A = I_B = 112.5445 \times 10^{-39}\ g\ cm^2$ and $I_C = 153.5823 \times 10^{-39}\ g\ cm^2$.

The vibrational frequencies obtained from the Raman spectra of $PSBr_3$ were reported by Delwaulle and Francois (6).

Ground State Quantum Weight: [2] σ = [3]
Point Group: [C_{3v}]
Bond distance: Si-Br = [2.17]Å
Bond Angle: Br-Si-Br = [111.36]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [1.29082 x 10^{111}] g^3 cm^6

Enthalpy of Formation

The enthalpy of formation of $SiBr_3(g)$ is based on an assumed average bond energy of 78±5 kcal mol^{-1} (1). This average bond energy is that of $SiBr_4(g)$, i.e. $\Delta_a H°(SiBr_4, g,)/4$. The rationale for this assumption is based on the same relationship existing for the silicon chloride and fluoride species (1).

Heat Capacity and Entropy

The molecular structure is assumed to be identical to the $SiBr_3$ group in $SiHBr_3$ (1). From this structure we estimate the following principal moments of inertia: $I_A = I_B$ = 87.0168 x 10^{-39}, and I_C = 170.479 x 10^{-39} g cm^2. The vibrational frequencies are assumed to be those of the $SiBr_3$ group in $SiHBr_3(g)$.

$S°(298.15\ K) = 176.4 \pm 3.3\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 179.9\ K$

$\Delta_f H°(0\ K) = -531.6 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -550.2 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 0\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of $TiBr_3$(cr) is based on the vapor pressure data reported by Hall and Blocher (1) for the process $1/2Hg_2Br_2(cr) + TiBr_3(cr) = TiBr_4(g) + Hg(\ell)$ over the temperature range 430 to 546 K. 2nd and 3rd law analyses of these data give values for the enthalpy of reaction of 24.2±0.3 and 24.4 kcal mol^{-1}, respectively, for seventy three points, with ten points rejected due to failure of a statistical test. The 3rd law drift in the data is calculated as 0.6±0.8 cal K^{-1} mol^{-1}. The 3rd law value of 24.4 kcal mol^{-1} is combined with the JANAF enthalpies of formation of $TiBr_4(g)$ and $HgBr_2(cr)$ to obtain the adopted enthalpy of formation, $\Delta_f H°(cr, 298.15\ K) = -131.5 \pm 2.0$ kcal mol^{-1} (-550.196±8.4 kJ mol^{-1}).

Heat Capacity and Entropy

The heat capacity and entropy of $TiBr_3$(cr) have been measured over the temperature range 51 to 800 K by King et al. (2). Heat capacities above 800 K are estimated from graphical extrapolation. The value of S°(298.15 K) is derived from these data, based on S°(51 K) = 8.60 cal K^{-1} mol^{-1}. The value of S°(51 K) is estimated from a Debye-Einstein extrapolation of the measured heat capacities, the equation being $C_p° = D(70.0/T) + E(120/T) + 2E(306/T)$. It is assumed that all electronic entropy is contained within the measured and extrapolated heat capacities.

Transition Data

A second order transition at 179.9 K was observed by King et al. (2). The heat capacity at this temperature is in excess of 56.1 cal K^{-1} mol^{-1}. King et al. (2) measured the value of H°(188 K) -H°(160 K) as 0.773 kcal mol^{-1}.

Sublimation Data

The enthalpy of sublimation is calculated from the enthalpies of formation of $TiBr_3$(cr) and $TiBr_3$(g) at the sublimation temperature. *The sublimation temperature is taken as the point at which $\Delta_r G = 0$ for the process $TiBr_3(cr) = TiBr_3(g)$ at one bar.*

Enthalpy of Formation

The enthalpy of formation of $TiBr_3(g)$ is calculated from the enthalpy of sublimation of $TiBr_3(cr)$. A tentative equation for the vapor pressure of $TiBr_3(cr)$ was reported by Hall and Blocher (1). 2nd and 3rd law analyses of the equation over the temperature range 700 to 900 K give values of $\Delta_{sub}H°(298.15\ K)$ of 45.2 and 41.9 kcal mol^{-1}, respectively, with a 3nd law drift of -4.2 cal K^{-1} mol^{-1}. The chosen value of $\Delta_f H°(298.15\ K)$, -89.6±2.5 kcal mol^{-1} (-374.886±10.5 kJ mol^{-1}), is based on the 3rd law $\Delta_{sub}H°(298.15\ K)$.

Heat Capacity and Entropy

The interatomic distance is estimated from those of $TiCl_4$, $TiCl_3$ and $TiBr_4$. The pyramidal bond angle is estimated assuming that $TiBr_3(g)$ is similar to the group V trihalides. The principal moments of inertia are: $I_A = I_B = 98.0035 \times 10^{-39}$ g cm^2 and $I_C = 179.3970 \times 10^{-39}$ g cm^2. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} (2).

PREVIOUS: June 1968 (1 atm) CURRENT: June 1968 (1 bar)

$S°(298.15\ K) = [172.05]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-616.1 \pm 67]\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-636.0 \pm 67]\ kJ\ mol^{-1}$

Enthalpy of Formation

Larsen and Leddy (1) studied the reaction Zr(cr) + 3 $ZrBr_4$(g) = 4 $ZrBr_3$(cr) in the temperature range 473 to 973 K and pressure range 5 to 15 atm. They present a plot of the fractional reaction, for a series of temperatures, as a function of the reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The Gibbs energy function change for this reaction was calculated at 100 K invervals from 500 to 1100 K. At each temperature, the equilibrium constant was assumed to be 1, and $\Delta_r H(298.15\ K)$ accordingly calculated. These values and the enthalpy of formation of $ZrBr_4$(g) [see $ZrBr_4$ table] were used to compute a series of values for the standard enthalpy of formation of $ZrBr_3$(cr). The following table gives representative values at four temperatures.

T/K	K_p	$\Delta_r H°(298.15\ K)$	$\Delta_f H°(ZrBr_3, cr, 298.15\ K)$
500	1	-70.26 kcal mol^{-1}	-132.8 kcal mol^{-1}
700	1	-96.48 kcal mol^{-1}	-139.3 kcal mol^{-1}
900	1	-121.75 kcal mol^{-1}	-145.6 kcal mol^{-1}
1100	1	-146.28 kcal mol^{-1}	-151.8 kcal mol^{-1}

If one assumes an initial pressure of from 0 to 10 atm for $ZrBr_4$ and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of $ZrBr_4$ to attain a value of 1 atm and hence an equilibrium constant of 1. The data of Larsen and Leddy (1) indicate about 82% reaction at 973 K. It was assumed that around 1100 K the equilibrium constant attains a value of 1 giving -152 kcal mol^{-1} (-635.968 kJ mol^{-1}) for the enthaply of formation of $ZrBr_3$(cr) at 298.15 K. The limits of error were taken to be ±16 kcal mol^{-1} which corresponds to a ±500 K temperature spread in the above table.

A 2nd law calculation of their data was carried out but the results are of doubtful value in view of the uncertainty in the attainment of equilibrium at the lower temperatures.

Heat Capacity and Entropy

The heat capacity was estimated in the same manner as for $ZrBr_4$(cr) [see $ZrBr_4$(cr) table]. The values for θ_D and θ_E were taken to be the same as those estimated for $ZrBr_4$(cr). The internal contribution was obtained from the estimated $ZrBr_3$ vibrational frequencies and the anharmonicity factor "a" was taken to be 2.5×10^{-3}. The specific heat above 300 K was obtained by graphical extrapolation.

It was assumed, in the above estimation, that the crystalline lattice is made up of $ZrBr_3$ molecules. However, Holze (2) concluded that crystalline ZrI_3 was composed of a chain lattice of $(Zr_2I_6)_n$ units. A chain lattice of $[Zr_2Br_6)_n$ units is probably a better representation of the solid state structure of $ZrBr_3$. Until more quantitative data becomes available, however, it is felt that the above analysis gives a fair approximation to the heat capacity of $ZrBr_3$.

Disproportionation Data

As detailed above, this was assumed to be 1100 ± 500 K.

Liquid Phase

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data

The enthalpy of sublimation at 298.15 K was obtained from the difference in the enthalpy of formation of the gas and solid at 298.15 K. The sublimation point was obtained from the Gibbs energy crossover between gas and solid at one bar.

Enthalpy of Formation

The enthalpies of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides are computed from data issued in these JANAF tables. The zirconium-halide bond energy, taken as 1/4 of this enthaply of formation, is found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it is found that the bond energy of the trichloride is around 7 kcal mol^{-1} greater than that for titanium tetrachloride. This amount is added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, is found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium is determined from this curve and their estimated bond distances.

For zirconium tribromide, the enthaply of formation from the gaseous atoms is -329 kcal mol^{-1} and from the elements in their standard state, -103 kcal mol^{-1} (-430.952 kJ mol^{-1}).

Heat Capacity and Entropy

The measured internuclear distances for the tribromides of P, As, and Sb are plotted as a function of the atomic weight of these atoms and a smooth curve is drawn through the points. The internuclear distance for $ZrBr_3$ is taken from this plot. The bond angle is assumed to be intermediate between the bond angles of $AsBr_3$ and $SbBr_3$; it is taken to be 98°. The principal moments of inertia are: $I_A = I_B$ = 101.4161 x 10^{-39} gm cm^2, I_C = 172.6792 x 10^{-39} g cm^2.

The measured vibrational frequencies for the tribromides of phosphorus, arsenic, and antimony are plotted as a function of internuclear distance. Smooth curves through these points are obtained for ν_1, ν_2, and ν_4; these curves and the estimated $ZrBr_3$ bond distance are used to obtain correlation values of ν_1, ν_2, and ν_4 for $ZrBr_3$. Force constants, assuming a valence force field and a Br-Zr-Br angle of 98°, are derived from the above values for ν_1 and ν_2. These force constants are then used to derive values for ν_3 and ν_4. By a process of successive approximation, a set of force constants are obtained which give frequencies in good agreement with the three correlation values. The three correlation frequencies and the derived frequency are used in this table.

Enthaply of Formation

The chemical equilibria, 622-665 K, for the reaction $Fe_2Br_4(g)$ = 2 $FeBr_2(g)$ were studied by Porter and Schoonmaker (1), using a mass spectrometer. Based on the reported partial pressures for the two species, the enthalpy change $\Delta_r H°(298.15\ K)$ for the reaction is evaluated by both the 2nd and 3rd law method to be 40.36±2.0 and 40.75±0.2 kcal mol^{-1}, respectively. Using the 3rd law $\Delta_r H°$ value and $\Delta_f H°(FeBr_2, g, 298.15\ K)$ = -9.9±0.5 kcal mol^{-1}, the enthaply of formation $\Delta_f H°(Fe_2Br_4, g, 298.15\ K)$ is calculated as -60.5±2.0 kcal mol^{-1} (-253.132 kJ mol^{-1}) and is adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be planar. The two Fe atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two Br atoms. The two remaining Br atoms are situated outside the square on a straight line joining the two Fe atoms. The Fe-Br bond distance was estimated to be the same as that in the $FeBr_2(g)$ molecule. The first six vibrational frequencies were estimated by comparison with those for $K_2Br_2(g)$ calculated by Berkowitz (2). The last three degenerate frequencies were assigned arbitrarily in order to give good second and third law agreement for the heats of dissociation of dimer to monomer. The order of the frequencies listed above is arbitrary and not related to their species types.

The electronic levels and quantum weights were estimated by comparison with those for $FeBr_2(g)$. The principal moments of inertia are: I_A = 66.5764 x 10^{-39}, I_B = 434.5679 x 10^{-39} and I_C = 501.1443 x 10^{-39} g cm^2.

Enthalpy of Formation

$\Delta_f H°$ of the dimer is based on an analysis of mass spectrometric data reported by Berkowitz and Marquart (11) These studies have revealed the presence of approximately 2% dimer in the equilibrium vapor over $MgBr_2$(cr) at around 800 K. The existence of the dimer was inferred from the observed ion intensities for $Mg_2Br_3^+$. Berkowitz and Marquart (1) reported a 2nd law $\Delta_r H$(803 K) of 12.9 kcal mol^{-1} for the process $MgBr_2(cr) + MgBr_2(g) = Mg_2Br_4(g)$. When corrected to 298.15 K this value gives $\Delta_r H°$ = 14.0 kcal mol^{-1} which leads to $\Delta_f H°(Mg_2Br_4, g, 298.15\ K)$ = -183.7 kcal mol^{-1}. The absolute pressure of $Mg_2Br_4(g)$ was also measured at 798 K by integrating the ion current during complete volatilization of a previously weighed sample. A 3rd law analysis of the reported pressure gives $\Delta_{sub} H°(298.15\ K)$ = 67.4 kcal mol^{-1} for 2 $MgBr_2(cr) = Mg_2Br_4(g)$. This value for the enthalpy of sublimation leads to $\Delta_f H°(Mg_2Br_4, g, 298.15\ K)$ = -183.2 kcal mol^{-1} which is in excellent agreement with the 2nd law result. We adopt an average value (-183.5 kcal mol^{-1}, -767.764 kJ mol^{-1}) of these two results. The uncertainty in $\Delta_f H°$ is estimated as ±5.0 kcal mol^{-1}, and the adopted $\Delta_f H°$ value value corresponds to a dimerization energy for $MgBr_2(g)$ of 38.7 kcal mol^{-1}.

Heat Capacity and Entropy

The dimer molecule is assumed to have a bridge-bond structure of D_{2h} symmetry similar to that suggested by Thompson and Carlson (2) for the dimers of several transition metal dichlorides. The two outer Mg-Br bond lengths are assumed to be the same as that for $MgBr_2$(3)(2.34 Å). The four ring Mg-Br'(bridge) bond lengths are taken to be somewhat longer (2.6 Å). The four atoms which lie in the ring form a square. The Br'(bridge)-Mg-Br bond angle is estimated as 135°. The principal moments of inertia are: $I_A = 89.6957 \times 10^{-39}$, $I_B = 490.6138 \times 10^{-39}$, and $I_C = 580.3094 \times 10^{-39}$ g cm^2.

The vibratonal frequencies of the ring (first six listed) are taken equal to those for Na_2Br_2 (3). These frequencies were obtained by Berkowitz (4) from ionic model calculations. The remaining six frequencies are estimated by analogy with those for $MgBr_2$ and Mg_2Cl_4 (3). Following the observations made by Thompson and Carlson (2), all of the dimer frequencies are assumed to lie above the bending frequency (ν_2 = 70 cm^{-1}) of the monomer (3). Our adopted functions for the monomer and dimer reproduce the pressures measured by Berkowitz and Marquart (1) and show that the dimer becomes an increasingly important vapor species with rising temperatures.

PREVIOUS: June 1974 (1 atm) CURRENT: June 1974 (1 bar)

$S°(298.15\ K) = [209.2 \pm 17]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -304.2 \pm 8\ kJ\ mol^{-1}$

Enthalpy of Formation

Shchukarev et al. (1) have measured the enthalpy of solution of $MoBr_4$(cr) from which Dellien et al. (2) have obtained $\Delta_f H°(MoBr_4, cr, 298.15\ K) = -70.35\ kcal\ mol^{-1}$. Brewer (3) has reviewed the equilibrium data of Oppermann (4) (see the discussion on the $MoBr_4$(g) table (5)) as well as the above measurements and obtained $\Delta_f H°(298.15\ K) = -72.7 \pm 2\ kcal\ mol^{-1}$ ($-304.177\ kJ\ mol^{-1}$) which is the value adopted here. This differs from the value $\Delta_f H°(298.15\ K) = -76.8\ kcal\ mol^{-1}$ adopted by NBS (6).

Heat Capacity and Entropy

Brewer (3) estimated $C_p°(298.15\ K) = 31.8 \pm 2\ cal\ K^{-1}\ mol^{-1}$ and $S°(298.15\ K) = 50.0\ cal\ K^{-1}\ mol^{-1}$ ($209.200\ kJ\ mol^{-1}$). Other estimates are $C_p°(298.15\ K) = 29.5\ cal\ K^{-1}\ mol^{-1}$ from the ionic contributions of Kubaschewski and Unal (7) and $S°(298.15\ K) = 51.4\ cal\ K^{-1}\ mol^{-1}$ from the additive entropy constants of Stull and Prophet (8). We adopt Brewer's values (3) of $C_p°$ and S° at 298.15 K and estimate $C_p°$ at higher temperatures by comparison with $MoBr_2$(cr) and $MoBr_3$(cr) (5).

Decomposition Data

T_{dcm} is the calculated temperature at which $\Delta_r G° = 0$ for the reaction $MoBr_4(cr) = MoBr_3(cr) + 0.5\ Br_2(g)$. Carnell et al. (9) have given conditions for the formation of $MoBr_4$(cr) and its dissociation to $MoBr_3$(cr).

Point Group: T_d

Bond Distance: Mo-Br = 2.39 ± 0.02

Bond Angle: Br-Mo-Br = 109.47°

Product of the Moments of Inertia: $I_A I_B I_C = 8.25596 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

Oppermann (1) made careful pressure measurements on the systems $MoBr_3$(cr) + Br_2(g), $MoBr_{2+x}$(cr) + $MoBr_{3-y}$(cr) and $MoBr_2$(cr) + Mo(cr). Brewer (2), by comparison with the tungsten-bromide system, indicated the possibility of intermediate phases between $MoBr_2$ and $MoBr_3$ and thus modified the treatment of the data. Brewer used a 3rd law treatment combined with independent data on the enthalpies of formation of $MoBr_2$(cr), $MoBr_3$(cr) and $MoBr_4$(cr) and removed the restriction that x=0 and y=0. For this reason we adopt the value of $\Delta_f H°(298.15\ K)$ obtained by Brewer, -40.9±2 kcal mol^{-1} (-171.126 kJ mol^{-1}), rather than the value of -36.7 kcal mol^{-1} reported by Dellien et al. (7).

Heat Capacity and Entropy

Brewer (2) used a slight modification of the vibrational frequencies and internuclear distance estimated by Lofgren (3). He assumed an Mo-Br distance of 2.42 Å in all the molybdenum bromides. The electron diffraction study of Spiridonov and Romanov (4) established the structure of $MoBr_4$(g) to be a regular tetrahedron with an Mo-Br distance of 2.39±0.02 Å (5). This is the value adopted here. Our value for the product of the moments of inertia $I_A I_B I_C = 8.256 \times 10^{-111}\ g^3\ cm^6$ is 8% lower than Brewer's value ($8.898 \times 10^{-111}\ g^3\ cm^6$). This reduces S° by 0.1 cal $K^{-1}\ mol^{-1}$ at all temperatures. Electronic levels are assumed to be the same as the MoF_4 levels (6), which Brewer [2] estimated from crystal field theory.

Ground State Quantum Weight: [1] $\sigma = 12$
Point Group: [T_d]
Bond Distance: Pb-Br = [2.58] Å
Bond Angle: Br-Pb-Br = [109° 28']
Product of Moments of Inertia: $I_A I_B I_C = [1.30647 \times 10^{-110}]\ g^3\ cm^6$

Enthalpy of Formation

The adopted $\Delta_f H°(0\ K) = -101.9 \pm 20$ kcal mol^{-1} (-426.350 ± 84 kJ mol^{-1}) is derived from the dissociation energy for the *process* $PbBr_4(g) = Pb(g) + 4\ Br(g)$. D_0^o *= 11.34 eV is estimated from an intercomparison of the lead mono-, di-, and tetra-*halides (1). This adopted D_0^o value for $PbBr_4(g)$ is greater than the D_0^o value for $PbBr_2(g)$ by a factor of 2.09. The auxiliary values $\Delta_f H°(Pb, g, 0\ K)) = 46.91$ kcal mol^{-1} (1) and $\Delta_f H°(Br, g, 0\ K) = 28.188$ kcal mol^{-1} (1) are used. $\Delta_f H°(PbBr_4, g, 298.15\ K) = -109.1 \pm 20$ kcal mol^{-1} (-456.361 ± 84 kJ mol^{-1}) is calculated from $\Delta_f H°(0\ K)$.

Heat Capacity and Entropy

The molecular constants and vibrational frequencies are those calculated by Aleksandrovskaya et al. (2). Later works (3, 4, 5) mistakenly cite this work as observed data and use a bond distance of 2.54 Å rather than the 2.58 Å originally published (2).

The principal moments of inertia are $I_A = I_B = I_C = 23.5227 \times 10^{-39}\ g\ cm^2$.

PREVIOUS: December 1973 (1 atm) CURRENT: December 1973 (1 bar)

$S°(298.15\ K) = [278.24 \pm 1.3]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 278.4 \pm 1.0\ K$

$\Delta_f H°(298.15\ K) = -457.31 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H°$ = unknown

Enthalpy of Formation

Schafer and Heine (1) measured the enthalpy of solution of Si(cr) in an HF solution containing AgF. For the overall reaction $SiBr_4(\ell) + 4\ Ag(cr) = Si(cr) + 4\ AgBr(cr)$, they reported $\Delta_r H°(298.15\ K) = +13.3\ kcal\ mol^{-1}$. Using auxiliary data for AgBr (2), we calculate $\Delta_f H°(298.15\ K) = -109.3\ kcal\ mol^{-1}$ ($-457.311\ kJ\ mol^{-1}$) for $SiBr_4(\ell)$. We adopt this value and assign an uncertainty of $\pm 2.0\ kcal\ mol^{-1}$.

Wolf et al. (3) studied the enthalpies of solution of $SiBr_4(\ell)$ and $Na_2SiO_3(cr)$ in caustic solution. The net reaction of interest, $SiBr_4(\ell) + 6\ NaOH(cr) = Na_2SiO_3(cr) + 4\ NaBr(cr) + 3\ H_2O(\ell)$, yielded $\Delta_r H°(298.15\ K) = -199.32\ kcal\ mol^{-1}$ based on the appropriate combination of results from five solution studies. Using current auxiliary data (4, 5), we update this value to $\Delta_r H°(298.15\ K) = -198.06\ kcal\ mol^{-1}$ and calculate $\Delta_f H°(298.15\ K) = -114.8\ kcal\ mol^{-1}$ for $SiBr_4(\ell)$. This data is suspect due to uncertainties in the conversion of data from Na_2SiO_3 (calorimetric solution) to $Na_2SiO_3(cr)$. The final state of the calorimetric solution is not well defined or well known and thus large uncertainties result.

Heat Capacity and Entropy

The heat capacity from 25°-100°C was determined calorimetrically within 2% by Sladkov (6). The constant value of 35.0 $cal\ K^{-1}\ mol^{-1}$ is extrapolated to 800 K. The entropy at 298.15 K is chosen so as to bring the 2nd and 3rd law analysis of the vapor pressure data into agreement.

Fusion Data

Pohland (7) reported the melting point of $SiBr_4$ to be 5.2 °C (±1 °C). No data are available on the enthalpy of fusion

Vaporization Data

T_{vap} is calculated as that temperature for which $\Delta_r G° = 0$ for the process $SiBr_4(\ell) = SiBr_4(g)$ [f = 1 bar]. $\Delta_{vap} H°$ is calculated as the difference between the $\Delta_f H°$ values for the ideal gas and the liquid at T_{vap}. Normal boiling points (p = 1 atm) reported in the literature are 426.0 K (7) and 426.6 K (8), and 427.8 K (766 mm Hg, 9). A normal boiling point (p = 1 bar) should be slightly lower than our calculated T_{vap} which corresponds to f = 1 bar. Refer to the $SiBr_4(g)$ table for a possible explanation of this discrepancy.

$S°(298.15\ K) = 379.36 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -385.55 \pm 16.7\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -415.47 \pm 16.7\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
246.7(1)	494 (3)
84.8(2)	133.6(3)

Ground State Quantum Weight: [1] $\sigma = 12$
Point Group: T_d
Bond Distance: Si-Br = 2.15 ± 0.02 Å
Bond Angle: Br-Si-Br = 109.47122°
Product of the Moments of Inertia: $I_A I_B I_C = 4.37533 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation Pohland (1) has studied the vaporization of $SiBr_4$ from 260-426 K (0.8-755.5 mm Hg). This vapor pressure data (20 points) is corrected for vapor non-ideality by means of the equation $\Delta G°/T = -R \ln p - Bp/T$. The Berthelot equation of state and critical constants T_c = 656 K and P_c = 41.3 atm as suggested in the review article by Lapidus et al. (2) are used to calculate B. The recent study on orthobaric densities by Nisel'son et al. (3) reported T_c = 663 K. The use of this latter value does not significantly affect the results.

A 2nd and 3rd law analysis of this corrected data (1) yields $\Delta_{vap}H°(298.15\ K) = 10.0\ kcal\ mol^{-1}$. The entropy of the liquid at 298.15 K is adjusted so as to bring the 2nd and 3rd law results into agreement. This treatment suggests that the five lowest pressure data points (260-345 K, 0.8-60.3 mm Hg) are biased. These five points are not included in the above analysis. Any vapor pressure equation used to represent this data will be significantly altered in neglecting these five data points.

We adopt $\Delta_{vap}H°(298.15\ K) = 10.0\ kcal\ mol^{-1}$ which leads to $\Delta_f H°(298.15\ K) = -99.3\ kcal\ mol^{-1}$ ($-415.471\ kJ\ mol^{-1}$) (4). Using auxiliary data (4), we calculate $\Delta_{at}H°(SiBr_4, g) = 311.54\ kcal\ mol^{-1}$ ($1303.48\ kJ\ mol^{-1}$). This value is 4.03 times the dissociation energy of SiBr(g) (4).

Heat Capacity and Entropy

The adopted vibrational frequencies are from the work of Clark and Rippon (5), who recorded the Raman spectra in the vapor phase (210°C). The spectral data were interpreted in terms of a tetrahedral structure. This structure is consistent with the electron diffraction data of Lister and Sutton (6), Yamasaki et al. (7), and Spitzer et al. (8), which suggested a tetrahedral structure with a Si-Br bond distance of 2.15±0.02 Å. We adopt this bond distance. The principal moments of inertia are: $I_A = I_B = I_C = 163.5574 \times 10^{-39}\ g\ cm^2$. Shimanouchi, in a recent compilation of molecular vibrational frequencies (9), suggested somewhat different values (249, 90, 487, 137 cm^{-1}) based on earlier infrared and Raman studies by Trumpy (10), Delwaulle (11), and Radhakrishnan (12), and Long et al. (13). These frequencies would lead to a S°(298.15 K) value of 90.3 cal $K^{-1}\ mol^{-1}$ (377.9 J $K^{-1}\ mol^{-1}$). Much literature has been published on the inter-relationships between force constants and vibrational frequencies. Since the majority of this work was published prior to the Clark and Rippon study (5), it will not be further discussed or referenced. The same situation exists for temperature dependent thermochemical tabulations of $SiBr_4(g)$.

TITANIUM BROMIDE ($TiBr_4$) CRYSTAL M_r = 367.496

$S°(298.15\ K) = 243.6 \pm 6.7\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 311.4\ K$

$\Delta_f H°(0\ K) = -592.68 \pm 4.6\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -617.98 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 12.887\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(TiBr_4, cr, 298.15\ K)$ has been determined calorimetrically by several investigators as follows.

Source	Reaction	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Nelson et al. (1)	$Ti(cr) + 2\ Br_2(g) = TiBr_4(cr)$	-147.3 ± 1.1
Johnson et al. (2)	$TiCl_4(\ell) + 2\ Br_2(\ell) = TiBr_4(cr) + 2\ Cl_2(g)$	-147.6 ± 1.3
Schlafer and Schmidtke (3)	$Ti(cr) + 2\ Br_2(\ell) = TiBr_4(cr)$	-147.7 ± 0.3
Gross, et al. (4)	$Ti(cr) + 2\ Br_2(\ell) = TiBr_4(cr)$	-148.1 ± 0.3

The chosen value of $\Delta_f H°(298.15\ K) = -147.7 \pm 1.0$ kcal mol^{-1} (617.977 ±4.2 kJ mol^{-1}) is the average of these determinations. The value from the work of Nelson et al. (1) is obtained from their enthalpy of reaction and the JANAF value for the enthalpy of vaporization of bromine. The value obtained from Johnson et al. (2) is a combination of their enthalpy of reaction and the JANAF value for the enthalpy of formation of $TiCl_4(\ell)$.

Heat Capacity and Entropy

The heat capacity of $TiBr_4(cr)$ has been measured over the temperature range 51 to 298.15 K by King et al. (5). They reported a value of 42.74 cal K^{-1} mol^{-1} for S°(298.15 K)-S°(51 K) based on their measurements. The value of S°(51 K) is estimated as 15.46 cal K^{-1} mol^{-1}. King et al. (5) reported an estimate of 14.75±1.60 for the same quantity. The former estimate is used so that the values of ΔsubH°(298.15 K) obtained by both 2nd and 3rd law methods are in agreement. See $TiBr_4(g)$ table for details. The value of H°(51 K)-H°(0 K) is estimated as 0.372 kcal mol^{-1}. This estimate is based on a Debye-Einstein extrapolation of the measured heat capacity with vibrational contributions removed.

Fusion Data

The melting temperature and heat of melting were reported by King et al. (5).

PREVIOUS: June 1964 CURRENT: June 1968

$S°(298.15\ K)$ = [284.168] J K^{-1} mol^{-1}
T_{fus} = 311.4 K

$\Delta_f H°(298.15\ K)$ = [-605.345] kJ mol^{-1}
$\Delta_{fus} H°$ = 12.887 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(311.4\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

King et al. (1) reported the heat capacity of $TiBr_4(\ell)$ between the melting point and normal boiling point. $S°(TiBr_4, \ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The melting temperature and heat of melting were reported by King et al. (1).

Vaporization Data

The boiling temperature, T_{vap}, is taken as the point at which K_p = 1 for the reaction $TiBr_4(\ell) = TiBr_4(g)$ at one bar. The enthalpy of vaporization is calculated as the difference between $\Delta_f H°$ of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for $TiBr_4(g)$.

$S°(298.15\ K) = 398.60 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -520.3 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -550.2 \pm 5.0\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
229.5(1)	382 (3)
74 (2)	90.5(3)

Ground State Quantum Weight: 1 $\sigma = 12$
Point Group: T_d
Bond Distance: Ti-Br = 2.31 Å
Bond Angle: Br-Ti-Br = 109° 28'
Product of the Moments of Inertia: $I_A I_B I_C = 6.73056 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation of $_4$TiBr (g) is calculated from those of $_4$TiBr (cr) and $_4$TiBr (ℓ) and the enthalpies of reaction for the processes (A) $TiBr_4(cr) = TiBr_4(g)$ and (B) $TiBr_4(\ell) = TiBr_4(g)$. 2nd and 3rd law analyses of the vapor pressure data for these processes yield the following results. The first four investigations employed the spoon gauge method, the last investigation being a manometric determination.

Source	Reaction	Data Points	T/K	$\Delta_r H(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal $K^{-1}mol^{-1}$	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Boni, 1966 (1)	A	13	275-311	16.4±0.2	16.19	-0.6±0.5	-131.5
Funaki et al., 1961 (2)	B	14	385-493	12.2±0.3	12.92	1.6±0.3	-131.8
Seki, 1941 (3)	A	12	286-306	15.4±0.5	15.90	1.6±1.6	-131.8
Hall et al., 1958 (4)	B	89*	341-499	13.2±0.1	13.14	-0.1±0.1	-131.5
Keavney & Smith, 1960 (5)	A	14	287-310	16.1±0.3	16.14	0.2±0.8	-131.6

* Four points rejected due to failure of a statistical test.

The adopted value of -131.5 kcal mol^{-1}(-550.196 kJ mol^{-1}) is that obtained from the data of Hall et al. (4), whose 3rd law drift was adjusted to zero by changing the entropy of the crystal within its uncertainty.

Heat Capacity and Entropy

The interatomic distance was reported by Lister and Sutton (6). The tetrahedral configuration is confirmed by spectroscopic studies (7, 8). The principal moments of inertia are: $I_A \approx I_B = I_C = 188.8066 \times 10^{-39}\ g\ cm^2$.

The vibrational frequencies have been reported by Delwaulle and Francois (7) and by Miller and Carlson (8). These values are based primarily on the Raman and infrared spectra of $TiBr_4(\ell)$, the value of ν_3 being the only frequency measured for $TiBr_4(g)$.

The electronic spectra of $TiBr_4$ in solution have been measured by Dijkgraaf (9). Di Sipio et al. (10) have reported the near ultraviolet spectra of $TiBr_4(g)$. Both of these studies indicate that $TiBr_4$ has no low lying electronic levels which would contribute significantly to the entropy.

PREVIOUS: June 1968 (1 atm) *CURRENT: June 1968 (1 bar)*

$S°(298.15\ K) = [224.7 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 723 \pm 1\ K$

$\Delta_f H°(0\ K) = [-734.3 \pm 8.4]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -760.7 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

Turnbull (1) measured the enthalpies of reaction for the dissolution of the zirconium tetrahalides in caustic and in water. The reported enthalpies of reaction and the corresponding reactions may be combined to yield the following:

$$ZrBr_4(cr) + 4NaCl(aq) = ZrCl_4(cr) + 4NaBr(aq),\ \Delta_r H°(298.15\ K) = -8.10 \pm 0.9\ kcal\ mol^{-1}$$
$$ZrBr_4(cr) + 4Cl^-(aq) = ZrCl_4(cr) + 4Br^-(aq),\ \Delta_r H°(298.15\ K) = -9.83 \pm 0.6\ kcal\ mol^{-1}$$

Using auxiliary data (2, 4), we calculate $\Delta_f H°(298.15\ K) = -182.67$ and $-181.02\ kcal\ mol^{-1}$ for $ZrBr_4(cr)$ from these two reactions. We adopt a mean of these two values, $\Delta_f H°(298.15\ K) = -181.8\ kcal\ mol^{-1}$ ($-760.651\ kJ\ mol^{-1}$), and assign an uncertainty of $\pm 1.5\ kcal\ mol^{-1}$. This same value was suggested by NBS (3).

Heat Capacity and Entropy

There are no heat capacity and enthalpy data reported in the literature for $ZrBr_4(cr)$. The adopted heat capacity values are estimated so as to give reasonable trends in comparison with $ZrCl_4$ and ZrI_4 and to be consistent with the existing sublimation data.

The crystal data compilation of Donnay and Ondik (5) tabulated both $ZrCl_4$ and $ZrBr_4$ as cubic structures. Thus, the adopted heat capacity values are estimated so as to parallel those for $ZrCl_4$. The heat capacity values below 300 K are calculated by summing contributions due to hindered translations, librations, and internal vibrations of the crystal. The parameters used in the calculations are determined by a correlation with corresponding parameters for $ZrCl_4$ (6) and a consideration of the sublimation data for $ZrBr_4$ (6). The high temperature heat capacities are obtained graphically.

Fusion Data

The melting point was observed by Rahlfs and Fischer (7) to be 723±1 K and by Nisel'son (8) to be 723±0.5 K.

Sublimation Data

The sublimation data is treated in the $ZrBr_4(g)$ table (6). The enthalpy of sublimation is adopted as $\Delta H°(298.15\ K) = 27.7 \pm 0.3\ kcal\ mol^{-1}$ ($115.897 \pm 1.3\ kJ\ mol^{-1}$). The sublimation temperture, T_{sub}, is calculated as that temperature for which $\Delta_r G° = 0$ for the process $ZrBr_4(cr) = ZrBr_4(g)$ at one bar. Since T_{sub} is less than T_{fus}, the liquid phase is thermodynamically unstable at a pressure of one atmosphere.

Enthaply of Formation

The enthaply of formation for $ZrBr_4(g)$ is calculated from the enthaplies of formation and sublimation of $ZrBr_4(cr)$ at 298.15 K. The adopted value for the enthaply of sublimation, $\Delta_{sub}H°(298.15\ K) = 27.7 \pm 0.3$ kcal mol^{-1}, is based on the mean of the 3rd law results from the following sublimation data.

In analyzing the vapor pressure data for the four sublimation studies (1, 2, 3, 4), corrections were made for non-ideality by means of the equation $\Delta G°/T = -R\ln p - Bp/T$. The Berthelot equation of state and the critical constants T_c = 805.15 K and P_c = 42.9 atm, as reported by Nisel'son and Sokolova (5), are used to calculate B.

Source	Method	Data Points	T/K	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Rahlfs and Fischer (1)	static	15	538-633	27.85±0.24	27.78±0.09	-0.1±0.4	-154.02
Schlafer and Skoludek (2)	static	eqn	494-620	28.59	27.66	-1.7	-154.14
Berdonosova et al. (3)		17	489-606	28.87±0.12	28.03±0.12	-1.5±0.2	-153.77
Normanton and Shelton (4)	effusion	eqn	400-500	26.32	27.30	2.2	-154.50

For the enthalpy of sublimation, we adopt the mean of the 3rd law results and assign an uncertainty of ±0.3 kcal mol^{-1}. Combining the adopted $\Delta_{sub}H°(298.15\ K)$ value with the enthalpy of formation of $ZrBr_4(cr)$, $\Delta_f H°(298.15\ K) = -181.8 \pm 1.5$ kcal mol^{-1} (6), we calculate $\Delta_f H°(298.15\ K) = -154.1$ kcal mol^{-1} (-644.754 kJ mol^{-1}) for $ZrBr_4(g)$ and assign an uncertainty of ±2.0 kcal mol^{-1} (±8.4 kJ mol^{-1}).

Heat Capacity and Entropy

The adopted vibrational frequencies are from the work of Clark et al. (7, 8, 9), who recorded the Raman spectra of $ZrBr_4$ in the vapor phase (380-420°C). These studies by Clark et al. (7, 8, 9) indicated that $ZrBr_4$ is a tetrahedral monomer in the vapor phase. Shimanouchi, in his compilation of molecular vibrational frequencies (10), also adopted the values of Clark et al. (7, 8, 9) for $ZrBr_4(g)$. Rahlfs and Fischer (1), through vapor density measurements, had earlier concluded that $ZrBr_4$ was monomeric in the vapor phase.

Berdonosov et al. (11) referenced an electron diffraction study by Cherkasov (12) which showed that, in the vapor phase, the Zr-Br internuclear distance was 2.44±0.02 Å. We adopt this value. The principal moments of inertia are: $I_A = I_B = I_C = 210.6556 \times 10^{-39}\ g\ cm^2$.

Much literature has been published on the inter-relationships between force constants and vibrational frequencies. Since the majority of these articles are based on estimated frequencies, they will not be further discussed or referenced. The same situation is true for thermodynamic tabulations of $ZrBr_4(g)$. One exception is that Clark et al. (7) calculated thermodynamic properties based on their experimental vibrational frequencies. Their tabulation is very similar to ours in the range 100-1000 K; the difference in entropy being less than 0.02 cal K^{-1} mol^{-1} in this range.

PREVIOUS: June 1975 (1 atm) CURRENT: June 1975 (1 bar)

$S°(298.15\ K) = [258.78 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 527 \pm 3\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -556.05 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 24.016 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted value for the enthalpy of formation of $NbBr_5$(cr), $\Delta_f H°(298.15\ K) = -132.9 \pm 3.0$ kcal mol^{-1} (-556.054 ± 12.6 kJ mol^{-1}) is based on the study of the direct bromination of Nb(cr) by Gross et al. (1).

Shchukarev et al. (2) studied the hydrolysis of $NbBr_5$(cr). Using the experimental results reported by Shchukarev et al. (2) and auxiliary data (4, 5), we calculate, $\Delta_f H°(298.15\ K) = -135.5 \pm 1.2$ kcal mol^{-1}. Schafer and Heine (3) also determined the enthaply of formation of $NbBr_5$(cr) via calorimetric measurements of the heats of solution of Nb(cr) and $NbBr_5$(cr) in hydrofluoric acid. Using their data and auxiliary results (4, 5), we calculate $\Delta_f H°(298.15\ K) = -131.86 \pm 1.0$ kcal mol^{-1}. These two solution results (2, 3) are in reasonable agreement with the adopted value. The direct bromination (1) is thought to be the more reliable.

Heat Capacity and Entropy

The heat capacity and entropy are estimated in comparison with $NbCl_5$(cr) (4). As there is no low temperature heat capacity data reported in the literature, the entropy at 298.15 K is calculated from the equation $\Delta_{sub} S°(298.15\ K) = S°(g, 298.15\ K) - S°(cr, 298.15\ K)$; $S°(g, 298.15\ K) = 107.35$ cal $K^{-1}\ mol^{-1}$ as given in the $NbBr_5$(g) table (4) and $\Delta_{sub} S°(298.15\ K) = 45.5$ cal $K^{-1}\ mol^{-1}$ as suggested by comparison with $NbCl_5$ and $TaCl_5$ (4).

Fusion Data

See the liquid table for details.

Sublimation Data

The enthalpy of sublimation, $\Delta_{sub} H°(298.15\ K)$, is the difference between the $\Delta_f H°(298.15\ K)$ values for $NbBr_5$(g) and $NbBr_5$(cr). Two sublimation studies are summarized in the $NbBr_5$(g) table (4).

$S°(298.15\ K) = [274.005]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}H° = 527 \pm 3\ K$

$\Delta_f H°(298.15\ K) = [-545.074]\ kJ\ mol^{-1}$

$\Delta_{fus}H° = 24.016 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15)$ is calculated from that of $NbBr_5(cr)$ by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(527 K)-H(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be identical with that of $NbCl_5(\ell)$ (3) including the assumed glass transition at 350 K. The entropy at 298.15 K is calcualted in a manner analogous to that used for $\Delta_f H°(298.15\ K)$.

Fusion Data

The adopted melting point, T_{fus} = 527±3 K (254°C), is based on the studies by Nisel'son et al. (1) and Berdonosov et al. (2). The melting point was determined by Nisel'son et al. (1) from cooling curves, T_{fus} = 255 C. Berdonosov et al. (2) determined the melting point by three methods: T_{fus} = 252.0±1.5 based on an analysis of their vapor pressure data, T_{fus} = 255±2 based on visual observation, and T_{fus} = 254±1 based on cooling curves.

The heat of melting is chosen to be $\Delta_{fus}H°$ = 5.74±1.5 kcal mol^{-1} (24.016±6.3 kJ mol^{-1}). This value is consistent with the vaporization data and the thermodynamic functions we have adopted. The entropy of melting, $\Delta_{fus}S°$ = 10.89 cal K^{-1} mol^{-1} is somewhat lower than anticipated, based on the expected similarity with $NbCl_5$ and $TaCl_5$ as far as condensed phase dimerization is concerned (3).

Vaporization Data

T_{vap}, the normal boiling point, is calculated as that temperature for which the Gibbs energy approaches zero for the process $NbBr_5(\ell) = NbBr_5(g)$. $\Delta_{vap}H°$ is calculated as the difference between the $\Delta_f H°$ values for $NbBr_5(g)$ and $NbBr_5(\ell)$ at T_{vap}. Two vaporization studies are summarized in the $NbBr_5(g)$ table.

Enthalpy of Formation

The vapor pressures over $NbBr_5$(cr, ℓ) have been measured by Alexander and Fairbrother (1) and Berdonosov et al. (2). A 2nd and 3rd law analysis of their data is given below. The enthalpy of formation for $NbBr_5$(g) is derived from the sublimation data of Berdonosov et al. (2). Our 3rd law analysis of their data gives $\Delta_{sub}H°(298.15\ K) = 26.88\ kcal\ mol^{-1}$ which leads to the adopted value, $\Delta_f H°(298.15\ K) = -106.02\ kcal\ mol^{-1}$ ($-443.588\ kJ\ mol^{-1}$) for $NbBr_5$(g). The sublimation data of Alexander and Fairbrother (1) is not acceptable as it leads to a large entropy drift, $-45 \pm 6\ cal\ K^{-1}\ mol^{-1}$.

The enthalpy of melting is chosen as 5.74 kcal mol^{-1} so as to give reasonable entropy drifts for the vaporization data.

Source	Reaction[a]	Method	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}

[a]Reaction (A) $NbBr_5(\ell) = NbBr_5(g)$, (B) $NbBr_5(cr) = NbBr_5(g)$

[b]One point rejected due to a statistical test.

Heat Capacity and Entropy

Monomeric $NbBr_5$(g) was shown by Spiridonov and Romanov (4, 5), using electron diffraction techniques, to have a trigonal bipyramidal structure of D_{3h} symmetry: all the Nb-Br bond lengths being equal within expeirmental uncertainty, Nb-Br = 2.45±0.02 Å. Skinner and Sutton (3) earlier used electron diffraction techniques and had suggested the same structure although a square pyramidal structure was consistent with their experimental results. We adopt the results of Spiridonov and Romanov (4, 5). The principal moments of inertia are: $I_A = 238.9340 \times 10^{-39}$, $I_B = I_C = 278.7563 \times 10^{-39}\ g\ cm^2$. A normal coordinate treatment of $NbBr_5$(g) in the Urey-Bradley force fields was performed by So (7) using the reported vibrational frequencies of Beattie and Ozin (6). This work by So (7) was intended to check the correctness of the reported fundamental frequencies and predict those unobserved frequencies (ν_3, ν_4, ν_5). Beattie and Ozin (6) had recorded the gas phase Raman spectra of niobium and tantalum chloride and bromide. We adopt the results of So (7) which support the work of Beattie and Ozin (6).

PREVIOUS: December 1974 (1 atm) CURRENT: December 1974 (1 bar)

$S°(298.15\ K) = [272 \pm 21]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 559 \pm 10\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -311.7 \pm 13\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.154\ kJ\ mol^{-1}$

Enthalpy of Formation

Shchukarev and Kokovin (1) have measured calorimetrically the enthalpy of reaction $\Delta_r H°(298.15\ K) = -187.475 \pm 0.9$ kcal mol^{-1} for $WBr_5(cr) + 1/2\ Br_2(\ell) + 8NaOH(77.4H_2O) + Na_2WO_4(cr) + 6NaBr(cr) + 4H_2O(\ell)$. This leads to $\Delta_f H°(WBr_5, cr, 298.15\ K) = -74.5 \pm 3$ kcal mol^{-1} (-311.708 ± 13 kJ mol^{-1}), using $\Delta_f H°(NaOH \cdot 77.4H_2O, 298.15\ K) = -112.348$ kcal mol^{-1} (2), $\Delta_f H°(NaWO_4, cr, 298.15\ K) = -369.2$ kcal mol^{-1} (3), $\Delta_f H°(NaBr, cr, 298.15\ K) = -86.38$ kcal mol^{-1} (3) and $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.315$ kcal mol^{-1} (4).

Heat Capacity and Entropy

$C_p°(300\ K) = 6.2$ cal K^{-1} g-atom^{-1} and $C_p°(559\ K) = 7.25$ cal K^{-1} g-atom^{-1} are estimated using the method described by Kubaschewski and Evans (5). Between 300 K and 559 K, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, $S°(298.15\ K) = 65$ cal K^{-1} mol^{-1} (271.960 J K^{-1} mol^{-1}), is estimated from that of $WCl_5(cr)$ (3) and the entropy difference between bromides and chlorides. The latter is estimated to be 13 cal K^{-1} mol^{-1} based on an extrapolation to pentavalent compounds of the entropy values of bromides and chlorides given by Latimer (7). Both WBr_5 and WCl_5 are paramagnetic with an effective moment of about 1.1 Bohr magnetons as indicated by Figgis and Lewis (8).

Fusion Data

Shchukarev et al. (6) have found the melting point, 559 K, by the thermographic method and 568 K by the tensimetric method. The value of 559 K is adopted in the tabulation.

The heat of melting is calculated from the difference between the enthalpies of sublimation and vaporization at the melting point. The enthalpies are both calculated from a 2nd law analysis of the vapor pressure data reported by Shchukarev et al. (6), who gave the uncorrected enthalpy of fusion, 5 kcal mol^{-1}. This value, when corrected for $\Delta C_p°$ of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

TUNGSTEN BROMIDE (WBr_5) LIQUID M_r = 583.370

$S°(298.15\ K)$ = [293.341] J K^{-1} mol^{-1}

T_{fus} = 559 ± 10 K

$\Delta_f H°(298.15\ K)$ = [-298.059] kJ mol^{-1}

$\Delta_{fus} H°$ = 17.154 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(WBr_5, \ell, 298.15\ K)$ is calculated from that of WBr_5(cr) by adding the $\Delta_{fus}H°$ and the difference in enthalpy, H°(559 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be a constant, 7.25 cal K^{-1} $g\text{-}atm^{-1}$.

S°(298.15 K) is calcualted in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which the Gibbs energy of reaction $WBr_5(\ell) \rightarrow WBr_5(g)$ approaches zero. The difference between the enthalpies of formation for liquid and gas at the normal boiling point is $\Delta_{vap}H°$.

Shchukarev et al. (1) derived the boiling point 665 K and the enthalpy of vaporization 14.5±0.5 kcal mol^{-1} from vapor pressure data. Our 2nd law values, corrected for $\Delta C_p°$, are T_{vap} = 666 K and $\Delta_{vap}H°$ = 13.8 kcal mol^{-1}. The adopted values are significantly different because the 2nd law value of $\Delta_{vap}S$ is not adopted in the table.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $MoCl_5$ determined by electron diffraction (1). The bond distance is estimated to be the same as that in WBr_6(g). The principal moments of inertia are: I_A = 229.2811 x 10^{-39} and $I_B = I_C$ = 267.4946 x 10^{-39} g cm^2.

All vibrational frequencies are estimated from those of WCl_5(g) (2), using the average value of $\nu(WBr_5)/\nu(WCl_5)$ = 0.62 for modes which are independent of the central atom and 0.68 for modes involving the central atom. These average values of 0.62 and 0.68 are obtained from the ratios of corresponding vibrational frequencies of ReX_6^-, $SnX_6^=$ and $PtX_6^=$ summarized by Siebert (3) and Nakamoto (4).

The electronic levels and quantum weights are estimated to be the same as those in WCl_5(g) (2).

PREVIOUS: June 1967 (1 atm) CURRENT: June 1967 (1 bar)

TUNGSTEN BROMIDE (WBr_6) CRYSTAL M_r = 663.274

$S°(298.15\ K) = [313.8 \pm 21]\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 582\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -343.088\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

Shchukarev and Kokovin (1) have measured calorimetrically the enthalpy of reaction $\Delta_r H°(298.15\ K) = -180.0 \pm 0.8\ kcal\ mol^{-1}$ for $WBr_6(cr) + 8NaOH(77.4H_2O) + Na_2WO_4(cr) + 6NaBr(cr) + 4H_2O(l)$. This leads to $\Delta_f H°(WBr_6, cr, 298.15\ K) = -82.0 \pm 3\ kcal\ mol^{-1}$ ($-343.088 \pm 13\ kJ\ mol^{-1}$), using $\Delta_f H°(NaOH \cdot 77.4H_2O, 298.15\ K) = -112.348\ kcal\ mol^{-1}$ (2), $\Delta_f H°(Na_2WO_4, cr, 298.15\ K) = -369.2\ kcal\ mol^{-1}$ (3), $\Delta_f H°(NaBr, cr, 298.15\ K) = -86.38\ kcal\ mol^{-1}$ (3) and $\Delta_f H°(H_2O, l, 298.15\ K) = -68.315\ kcal\ mol^{-1}$ (4).

Heat Capacity and Entropy

$C_p°(300\ K) = 6.2\ cal\ K^{-1}\ g\text{-}atom^{-1}$ and $C_p°(582\ K) = 7.25\ cal\ K^{-1}\ g\text{-}atom^{-1}$ are estimated using the method described by Kubaschewski and Evans (5). Between 300 and 582 K, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, $S°(WBr_6, cr, 298.15\ K) = 75\ cal\ K^{-1}\ mol^{-1}$ ($313.800\ J\ K^{-1}\ mol^{-1}$), is estimated by assuming $S°(WBr_6, 298.15\ K) = S°(WCl_6, 298.15\ K) + 6[S°(Br^-, 298.15\ K) - S°(Cl^-, 298.15\ K)]$. The value, $S°(WCl_6, cr, 298.15\ K) = 57\ cal\ K^{-1}\ mol^{-1}$, is obtained from $WCl_6(cr, \alpha)$ (3); and the value, $S°(Br^-, 298.15\ K) - S°(Cl^-, 298.15\ K) = 3\ cal\ K^{-1}\ mol^{-1}$, is obtained from the average entropy values for Br^- and Cl^- ions given by Latimer (6) and Kelley (7).

Fusion Data

Shchukarev et al. (8) have found the melting point, 582 K, under 50 atm pressure of $Br_2(g)$ by the thermographic method. The heat of fusion is unknown.

[200](2)	[130](3)
[250](3)	[70](3)

Ground State Quantum Weight: [1] σ = [24]

Point Group: [O_h]

Bond Distance: W-Br = [2.40] Å

Bond Angle: Br-W-Br = [90°]

Product of the Moments of Inertia: $I_A I_B I_C = [2.85707 \times 10^{-110}]\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(WBr_6, g, 298.15\ K) = -58.1\ kcal\ mol^{-1}$ ($-243.090\ kJ\ mol^{-1}$) is calculated from that of the crystal plus the estimated enthalpy of sublimation $\Delta_{sub}H°(298.15\ K) = 23.9\ kcal\ mol^{-1}$ for $WBr_6(cr) \rightarrow WBr_6(g)$. The value of $\Delta_{sub}H°(298.15\ K)$ is assumed to be the same as that for $WCl_6(cr) \rightarrow WCl_6(g)$. See WCl_6 table (Dec. 31, 1966) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be an octahedron similar to those of $WF_6(g)$, and $WCl_6(g)$ determined by electron diffraction. The bond distance is estimated to be 2.40 Å by assuming $r_{W-Br} = r_{W-Cl} + (r_{Na-Br} - r_{Na-Cl})$. The bond distances, W-Cl, Na-Br and Na-Cl, are given in JANAF WCl(g) an NaBr(g) and NaCl(g) tables, as 2.26 Å, 2.50 Å and 2.36 Å, respectively. The principal moments of inertia are: $I_A = I_B = I_C = 305.7081 \times 10^{-39}\ g\ cm^2$.

All vibrational frequencies are estimated from those of $WCl_6(g)$ (1), using the average value of $\nu(WBr_6)/\nu(WCl_6) = 0.62$ for modes which are independent of the central atom and 0.68 for modes involving the central atom. These average values of 0.62 and 0.68 are obtained from the ratios of corresponding vibrational frequencies of $ReX_6^=$, $SnX_6^=$ and $PtX_6^=$ summarized by Siebert (2), and Nakamoto (3).

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

NIOBIUM CARBIDE ($NbC_{0.98}$) CRYSTAL M_r = 104.6772

$S°(298.15\ K) = 34.966 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -138.061 \pm 2.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -138.909 \pm 2.5\ kJ\ mol^{-1}$

Enthalpy of Formation

There are five oxygen bomb calorimetry studies on NbC reported in the literature (1-5) and one CO(g) equilibrium study (6). The adopted $\Delta_f H°(298.15\ K)$ value is derived from the calorimetric study of Huber et al. (3). These authors studied the combustion of eight NbC_x samples where x covers the range 0.686 to 0.984. For each composition six to eight combustions were performed. Huber et al. (3) reported that the combustions varied from 98.78 to 100% of completion. Corrections of the order 0.51% or less were made to the enthalpy of combustion value to account for impurities in seven of the eight samples. The correction was 3.33% for the x = 0.984 sample. The calculated heats of formation were fitted to a quadratic equation by the least squares method by Huber et al. (3). Each value was weighted inversely proportional to the square of its uncertainty. Using the quadratic equation for $\Delta_f H°(298.15\ K)$ and correcting for the JANAF value of $\Delta_f H°(Nb_2O_5, cr, 298.15\ K)$ (7), we interpolate to x = 0.98, calculate and adopt $\Delta_f H°(298.15\ K) = -33.20 \pm 0.6\ kcal\ mol^{-1}$. Due to the large error in the data points, a linear equation can be chosen to fit the data without making a statistically significant difference (3).

Huber et al. (3) and Storms (8) have reanalyzed much of the calorimetric and equilibrium data (1-6) for NbC_x (x = 0.686 to 0.984). A graphical comparison of the results (i.e., $\Delta_f H°(298.15\ K)$ values vs. x) indicated that the quadratic equation suggested by Huber et al. (3) is a satisfactory representation of the various $\Delta_f H°(298.15\ K)$ results for NbC_x. The shortcomings of the various studies have been discussed by Huber et al. (3) and Storms (8). For comparison, the oxygen combustion study by Mah (1) leads to $\Delta_f H°(298.15\ K) = -31.14 \pm 0.8\ kcal\ mol^{-1}$ for $NbC_{0.9445}$.

Heat Capacity and Entropy

There have been three low temperature heat capacity studies for NbC_x: Pankratz et al. (13) using a $NbC_{0.996}$ sample (52-296 K), Toth et al. (19) using five NbC_x samples where x = 0.77, 0.83, 0.86, 0.91, and 0.96 (1.5-18 K), and Sandernaw and Storms using three NbC_x samples where x = 0.702, 0.825, and 0.980 (7.5-320 K). In addition there are numerous high temperature heat capacity and enthalpy studies on various NbC_x samples (9-13), (15-18). The adopted heat capacity values are those suggested by Turchanin et al. (20). Their $C_p°$ values were represented by a five term equation for the range 0-3000 K and is a compromise of the reported data mentioned, all adjusted to the composition $NbC_{0.98}$.

Phase Data

NbC has a face centered cubic structure of the NaCl type (8). The NbC phase exists, following the phase diagram of Storms (8), from roughly $NbC_{0.70}$ to near $NbC_{0.99}$. At the NbC-C eutectic temperature of 3573±50 K, the phase limit is $NbC_{0.97}$.

$S°(298.15\ K) = 5.74 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is zero by definition for the adopted standard reference state of Achesson spectroscopic graphite, i.e. artificial graphite of spectroscopic grade which is graphitized near 2600°C in an Acheson-type elesctric furnace. This standard state was adopted by CODATA (1) in order to be more consistent with the samples used in determing $\Delta_f H°(298.15)$ of $CO_2(g)$. CODATA (1) cites references which show the effects of various graphite samples on $\Delta_f H°(CO_2)$. Their assigned uncertainty (1) of ±0.031 kcal/mol for $\Delta_f H°(CO_2)$ is a rough measure of the deviations of various high purity graphites from our standard state. Larger deviations occur in carbon samples which are impure or less completely graphitized or which have much disorder or high surface area. Gross deviations (up to several kcal/mol) have been found for other carbons; e.g., many "glassy" carbons appear to be more stable than graphite at elevated temperatures due to large $\Delta_f S$ values (2) which compensate for positive values of $\Delta_f H$.

Heat Capacity and Entropy

S°(298.15) and H°(298.15 K) - H°(0 K) are the values selected by CODATA (1) based on Cp° (13-301 K) of CS-grade Acheson graphite measured by DeSorbo and Tyler (3). DeSorbo's later study (3) gave minor corrections to Cp° and more information on his sample. Due to differences in Cp° of various graphites, we increase the uncertainty of S°(298.15) from ±0.029 (1) to ±0.05 cal K^{-1} mol^{-1}. The entropy extrapolation below 13 K was given (3) as 0.0041 cal K^{-1} mol^{-1}. Properties tabulated below 298.15 K are from our smoothing of the data (3). Cp° above 298.15 K is based on enthalpy data of McDonald (4) and West and Ishihara (5) and on Cp° data of Cezairliyan et al. (6, 7). Deviations of the enthalpy data from our table are -0.3 to +0.6% (4, omitting 341 and 1037 K) and 0.0 to -0.6% (5). Deviations of the Cp° equations (6, 7) from our table are much less than the estimated uncertainties of 3% (6) and 3 to 5% (7). The selected studies (4-7) show reasonable agreement in their regions of overlap even though they involve different grades of graphite. Together, they yield mutually consistent data extending up to 3800 K.

Discrepancies in other Cp data are of concern since no single type of graphite has been accurately measured over the whole temperature range. At all temperatures the many studies show unusually large differences, some of which are due to deviations of the graphite samples from our chosen standard state. For example, the Cp of natural (Ceylon) graphite (3) was found to be approximately 9% lower from 200 to 300 K, yielding values of S°(298.15) and H°(298.15 K) - H°(0 K) which are lower by 0.08 cal K^{-1} mol^{-1} and 21 cal mol^{-1}, respectively. Lutkov et al. (8) reported similar differences in Cp among two graphites and one pyrolytic carbon. Discrepancies are even larger below 30 K (9, 10) and above 3000 K (6, 10-15).

If there were a large bias in our Cp° at 300-1500 K or above 3000 K, it could affect the interpretation of data on vaporization and melting. New studies of various graphites by laser flash (16) and differential scanning calorimetry (17) tend to confirm our Cp° at 350-950 K, where the largest deviations (-3%) are roughly equal to the experimental error. More controversial are Cp (12) and enthalpy (13) studies which gave Cp curves that rise very rapidly near 3500 K. Recent pulse-heating data (7), however, gave a slowly rising Cp° which is linear up to 3800 K. Four Cp° studies (6, 7, 12, 14) and an enthalpy study (15) agree satisfactorily below 3500 K, so the discrepancy must be due to temperature-dependent differences in experimental methods or graphite samples. This is a region where some graphites degrade rapidly with emission of particles, leading to possible bias in Cp data. Moreover, Whittaker has proposed (18) that graphite is metastable in this region and slowly transforms to carbynes. If this is the case, then very rapid measurements (7) should yield Cp° data which are different and more appropriate to graphite. The rapidly rising enthalpy data (13) could be explained by Whittaker's proposal or by differences in the various graphite samples (13).

Sublimation Data

See the tables for C(g), $C_2(g)$, $C_3(g)$, $C_4(g)$, etc. The most abundant species is C_3. Recent analyses gave sublimation temperature values (corresponding to 1 atm total pressure of all carbon species) of 3895-4020 K (19) from carbon arc data, ≤4070 K (20) from mass-loss data at 0.1-11 atm, and approximately 3915 K (21) from extrapolation of mass-spectrometric data at low pressure. Earlier values for this controversial point (see below) were summarized by Palmer(22).

Fusion Data and Phase Data

Controversy surrounds the solid-liquid-vapor triple point which recent studies place either at approximately 4000 K and approximately 1 atm (18, carbyne form) or at 4130±30 K and 120±10 atm (23, pyrolytic graphite). We doubt the latter triple point because the temperature is displaced by 400 to 800 kelvins from the sublimation curves (19-22 and ref. cited therein). The nature of the observed phenomenon (22-24) has been questioned (18) as well as the measurement of temperature (18, 19, 24). Also controversial is Whittaker's proposal (18) that several carbyne forms are more stable than graphite above 2600 K. Evidence includes X-ray data which were interpreted (18) to indicate slow forward transitions, graphite → carbynes, but rapid reverse transitions. These transitions might explain discrepancies observed in various Cp curves but alternative explanations are possible. We retain graphite as the reference state at all temperatures; this arbitrary choice avoids the need to switch phases at the proposed transition point, sublimation point or melting point, all of which are subject to change.

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ = 171.29 ± 0.11 kcal mol^{-1} is the value selected by CODATA (1) based on $D_0^0(CO)$ = 89595 ± 30 cm^{-1} (256.165 ± 0.086 kcal mol^{-1}) from Douglas and Moller (2). The conversion factor used by CODATA (1) corresponds to the negligibly different value of 256.163 kcal mol^{-1}; this yields the adopted $\Delta_f H°$ when combined with $\Delta_f H°(CO, 0\ K)$ = -27.201 ± 0.024 kcal mol^{-1} (1, 3). According to Krupenie (4) it is most likely that the atomic dissociation products are in their ground states as assumed in the adopted $D_0^0(CO)$.

The enthalpy of sublimation, $\Delta_{sub}H° = \Delta_f H°$, is confirmed by Knudsen-effusion mass-spectrometric data of Wachi and Gilmartin (5) for graphite. They obtained absolute pressures from calibrations using gold and cobalt; pressures from the latter were higher by 8.74%. Our 3rd law analyses yield $\Delta_{sub}H°(298.15\ K)$ = 171.22 ± 0.61 and 170.78 ± 0.61 kcal mol^{-1} from gold and cobalt, respectively. 2nd law values are $\Delta_{sub}H°(298.15\ K)$ = 172.5 ± 3.3 kcal mol^{-1} and $\Delta_{sub}S°$(2nd law)- $\Delta_{sub}S°$(3rd law) = 0.5 ± 1.2 (gold) and 0.7 ± 1.2 (cobalt) cal K^{-1} mol^{-1}). The data consisted of 14 points in the range 2509-2753 K. None of the other studies of C(g) over pure graphite included calibrations for conversion of ion intensities to absolute pressures.

Heat Capacity and Entropy

The atomic energy levels are from Moore (6). $S°(298.15\ K)$ and $H°(0\ K) - H°(298.15\ K)$ are the same as the values selected by CODATA (1). Observed and predicted levels above 60333 cm^{-1} are omitted since they do not change the thermodynamic functions at 6000 K. At 14000 K the BETHE-FILL cut-off method would yield a Gibbs energy function ~0.1 cal K^{-1} mol^{-1} larger than either the present cut-off method (TEMPER, 7).

CARBON, ION (C^+) IDEAL GAS Mr = 12.01045

$IP(C^+, g) = 196664.7 \pm 0.5\ cm^{-1}$
$S°(298.15\ K) = 154.662 \pm 0.02\ JK^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1797.639 \pm 0.46\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [1809.435]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	$\varepsilon_i\ cm^{-1}$	g_i
$^2P_{1/2}$	0	2
$^2P_{3/2}$	63.42	4
$^4P_{1/2}$	43003.3	2
$^4P_{3/2}$	43025.3	4
$^4P_{5/2}$	43053.6	6

Enthalpy of Formation

$\Delta_f H°(C^+, g, 0\ K)$ is calculated from $\Delta_f H°(C, g, 0\ K)$ (1) using the spectroscopic value of IP(C) = 90820.42 ± 0.1 cm^{-1} (1086.454 ± 0.001 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(C^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(C, g, 0\ K)$ by using IP(C) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for C(g), $C^+(g)$, and $e^-(g)$. $\Delta_f H°(C \rightarrow C^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoritically predicted levels that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (6) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is 74930.1 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (6).

EA(C, g) = 1.2629 ± 0.0003 eV

$S°(298.15\ K)$ = 151.384 ± 0.003 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 589.33 ± 2 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [588.284] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^4S_{3/2}$	0.0	4
^2D	9920	10

Enthalpy of Formation

$\Delta_f H°(C^-, g, 0\ K)$ is calculated from $\Delta_f H°(C, g\ 0\ K)$ (1) using the adopted electron affinity of EA(C) = 1.2629 + 0.0003 eV (121.850 ± 0.029 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $C^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(C^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(C, g, 0\ K)$ by using EA(C) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $C^-(g)$, C(g), and $e^-(g)$. $\Delta_r H°(C^- \rightarrow C + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

Electronic energy levels are from the laser photodetachment study of Feldmann (3). He found that the $C^-(^2D)$ state has a binding energy of 0.033 ± 0.001 eV (266 ± 8 cm^{-1}) relative to ground state $C(^3P_0)$. The electronic energy of 9920 cm^{-1} is the difference in binding energy between ground and excited states. Spin-orbit splitting of the ^2D state was not resolved (3) but has been estimated (2, 4) to be 3 cm^{-1}. We neglect this splitting because its effect is negligible. $C^-(^2D)$ binding energies obtained by other mehtods (4, 7) are in satisfactory agreement.

Note that we include the excited state even though its binding energy is only 266 cm^{-1}. If this state were omitted, the Gibbs energy function (J K^{-1} mol^{-1}) would change by -0.004 (1700 K), -0.176 (3000 K) and -1.732 (6000 K).

$\omega_e = [760]\ cm^{-1}$ $\omega_e x_e = [5.0]\ cm^{-1}$ $\sigma = 1$

$B_e = [0.650]\ cm^{-1}$ $\alpha_e = [0.006]\ cm^{-1}$ $r_e = [1.77]$ Å

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was calculated from $D^0_0 = 83.0\ kcal\ mol^{-1}$, estimated by Gordon (1). The spectrum originally attributed to AlC(g) (2) was later shown to be due to $Al_2(g)$ (3, 4).

Heat Capacity and Entropy

Molecular constants were estimated by Gordon (1). The recent review by Huber and Herzberg (5) did not indicate any experimental data available for the vibrational-rotational constants for AlC(g).

BORON CARBIDE (BC) IDEAL GAS M_r = 22.821

$S°(298.15\ K)$ = [208.56] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 822.0 ± 41 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = 828.4 ± 41 kJ mol^{-1}

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^4\Sigma^-$	0	4

ω_e = [1350] cm^{-1} $\omega_e x_e$ = [12.0] cm^{-1} σ = 1
B_e = [1.555] cm^{-1} α_e = [0.018] cm^{-1}

Enthalpy of Formation

The enthalpy of formation at 298.15 K was calculated from $\Delta_f H°(0\ K)$ = 105±10 kcal mol^{-1} for the reaction BC(g) = B(g) + C(g) reported by Verhaegen et al. (1, 2).

Heat Capacity and Entropy

All spectroscopic constants were obtained from Gordon (3). Theoretical calculations by Kruba (4) predict a $^4\Sigma^-$ ground state. The recent review by Huber and Herzberg (5) did not indicate any experimental data available on the vibrational-rotational constants for BC(g).

PREVIOUS: June 1963 (1 atm) CURRENT: June 1963 (1 bar)

$S°(298.15\ K) = 27.175 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2743 \pm 20\ K$

$\Delta_f H°(0\ K) = -62.40 \pm 6.28\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -62.68 \pm 6.28\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [104.6 \pm 10]\ kJ\ mol^{-1}$

Enthalpy of Formation

Using a high temperature solution calorimetric technique, Hong and Kleppa (1) measured $\Delta_f H°(B_4C, cr, 1320\ K) = -15.98 \pm 0.84$ kcal mol^{-1}. We adopt this value and correct to 298.15 K using tabulated enthalpy data (2) to obtain $\Delta_f H°(B_4C, cr, 298.15\ K) = -14.98 \pm 1.5$ kcal mol^{-1} which is a correction to that reported by Hong and Kleppa (1). The uncertainty limit is that recommended by Hong and Kleppa.

Two additional experimental determinations of $\Delta_f H°(B_4C, cr, 298.15\ K)$ have been made. Smith, Dworkin, and Van Artsdalen (3) measured a value of $\Delta_r H°(298.15\ K) = -683.2 \pm 2.2$ kcal mol^{-1} for the reaction $B_4C(cr) + 4\ O_2(g) + 2\ B_2O_3(am) + CO_2(g)$. Due to the amorphous nature of the B_2O_3 product, a value of $\Delta_f H°(298.15\ K)$ derived from this reaction may be unreliable. Domalski and Armstrong (4) determined $\Delta_f H°(298.15\ K) = -17.1 \pm 2.7$ kcal mol^{-1} based on careful fluorine bomb calorimetry of the non-stoichiometric compound $B_{4.222}C(cr)$. The data were corrected to the stoichiometric $B_4C(cr)$ assuming the presence of excess free elemental boron. Note that the Hong and Kleppa result lies within the stated uncertainty limits of the Domalski and Armstrong value. In a review of similar data, Gurvich et al. (5) adopted a value for $\Delta_f H°(298.15\ K)$ of -14.82 ± 1.43 kcal mol^{-1}.

Heat Capacity and Entropy

The low temperature heat capacities, 54-294 K, were taken from Kelley (6). Above 298 K at least four enthalpy determinations have been made. The enthalpy data of King (7) in the range 298 to 1726 K were used to determine the equation: $C_p°/cal\ K^{-1}\ mol^{-1} = 22.99 + 5.40 \times 10^{-3}T - 10.72 \times 10^5 T^{-2}$. Similar measurements of Ancey-Moret and Deniel (8) lead to the equation $C_p°/cal\ K^{-1}\ mol^{-1} = 23.077 + 5.24 \times 10^{-3}T - 10.75 \times 10^5 T^{-2}$. Enthalpy measurements of Mathieu, Durand, and Bonnier (9) in the range 661-1014 K also support the latter two studies. We adopt the high temperature equation of King which joins smoothly at 298 K with the low temperature data of Kelley. The $S°(298.15\ K)$ is calculated based on the low temperature heat capacities of Kelley using $S°(53.1\ K) = 0.047$ cal $K^{-1}\ mol^{-1}$. The heat capacities adopted by Gurvich et al. (5) are in essential agreement with those adopted here up to 1500 K but are larger in the high temperature range (T>1500 K). This is due to the adoption (by Gurvich et al.) of the heat capacity results of Sheindlin et al. (10) which can be represented by the equation $C_p°/cal\ K^{-1}\ mol^{-1} = 22.65 + 5.27 \times 10^{-3}T - 12.82 \times 10^5 T^{-2} + 6.45 \times 10^{13}\ T^{-2}\exp(-33 \times 10^3/T)$. Note the additional exponential term which causes the high temperature disparity. Due to the relatively high impurity content of the material used (5.6 mole%) and also the thermodynamic propensity and endothermicity of the reaction by $B_4C(cr) = 4\ B(cr) + C(cr)$ at temperatures greater than 1500 K, we are in doubt as to the exponential behavior of $C_p°$ as reported in the Sheindlin study.

Fusion Data

Of the several reported values of the fusion temperature, T_{fus}/K, [2623(11, 13), 2723(12), 2713±20(10), 2633(14), 2743±20(15)], we adopt the value of Dolloff (15). The value for $\Delta_{fus}H°$ is estimated. Note that $B_4C(cr)$ decomposes at moderate temperatures to form B(cr, g) + C(cr) (2).

BORON CARBIDE (B_4C) LIQUID M_r = 55.251

$S°(298.15\ K) = [69.426]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [51.885]\ kJ\ mol^{-1}$

$T_{fus} = 2743 \pm 20\ K$ $\Delta_{fus}H° = [104.6 \pm 10]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(B_4C, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(B_4C, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(2743\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1750 K. The heat capacity below 1750 K is assumed to be that of the crystal. Above 1750 K the heat capacity is assumed constant and estimated as 135.98 J K^{-1} mol^{-1} or 27.196 J K^{-1} g-atom^{-1} (6.5 cal K^{-1} g-atom^{-1}).

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

PREVIOUS: CURRENT: June 1983

$S°(298.15\ K) = [16.3 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [2400]\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -90.79 \pm 10.5\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [75.312]\ kJ\ mol^{-1}$

Enthalpy of Formation

The selected $\Delta_f H°(298.15\ K)$ was calculated by the 3rd law method using vapor pressures reported by Pollock (1). Pressures for the reaction $Be_2C(cr) + 2Be(g) + C(graphite)$ were measured by Pollock in the temperature range 1430-1669 K by Knudsen technique. Vapor pressure data for this decomposition reaction have also been reported by Baboin (2), Quirk (3) and Muratov and Novoselova (4). The calculated $\Delta_f H°(298.15\ K)$ values are summarized as follows:

Calc. Method	Number of Pressures	T/K	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}	Source
3rd law	14	1430-1669	89.117	-21.7	Pollock (1)
2nd law	14	1430-1669	90.8	-25.1	Least squares fit of Pollock's v.p. to the equation: log P (atm) = 6.946-19,593/T
3rd law	6	1673-1953	71.411	+13.7	Muratov and Novoselova (4)
3rd law	8	1900-2600	81.278	- 6.1	Quirk (3)
3rd law	8	1600-2300	96.266	-36.0	Baboin (2)

Schick et al. (5) have listed the measured vapor pressures. The vapor pressures reported by Baboin (2) used in the 3rd law calculation were those listed by Schick, et al. (5).

Heat Capacity and Entropy

The heat capacity values, from 298.15 to 1200 K, were derived from; the mean $C_p°$ data measured by Neely et al. (6). Neely, et al., estimated an overall error of 15% in their mean heat capacity data. The powdered Be_2C material which was used analyzed 80 to 74% Be_2C. The impurities were mainly oxide and nitride of Be. No corrections were made for the effect of these impurities.

From 1200-2400 K the $C_p°$ was extrapolated so as to approach the value, 22 cal K^{-1} mol^{-1} calculated from Krikorian (7). The $S°(298.15\ K) = 3.9$ cal K^{-1} mol^{-1}, was estimated by Krikorian (7).

Fusion Data

Schick et al. (5), have summarized the available melting data i.e.: Oishi and Hamona (8) have reported decomposition upon heating as low as 1873 K. Brewer et al. (9) and Gaev (10) reported melting or dissociation between 2373 and 2423 K.

The melting point is assumed to be 2400 K as estimated by Douglas and Victor (11) and Schick et al. (5). From the estimated melting point, 2400 K, and an estimated 2.5 cal g-atom^{-1} for the entropy of melting, the heat of melting was calculated.

BERYLLIUM CARBIDE (Be_2C) LIQUID M_r = 30.03536

$S°(298.15\ K) = [47.467]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [2400]\ K$

$\Delta_f H°(298.15\ K) = [15.893]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [75.312]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(2400 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed constant and equal to the heat capacity of solid Be_2C at the estimated melting point. S°(298.15 K) is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The U. S. Nat. Bur. Stand. (1), states that Be_2C seems to decompose easily only at temperatures above its reported melting point. For this reason they extended their Be_2C table into the liquid region. For detailed fusion data see the crystal table.

Enthalpy of Formation

Dixon and Kroto (1) have observed predissociation of CBr(g) which indicates that the dissociation energy D_0^0 is less than 94.7 kcal mol^{-1}. They evaluated the kinetic data of Simons and Yarwood (2), obtaining a value of D_0^0 = 97±5 kcal mol^{-1}, based on the enthalpy of formation of bromoform and the dissociation energy of HBr, and concluded that the true value of D_0^0 is very close to the upper limit of 94.7 kcal mol^{-1}. Comparisons of C-X bond energies of CX_4 and CX compounds, however, indicate that this value is too high to be consistent with other carbon halides. Therefore the value of D_0^0 adopted is 75±15 kcal mol^{-1}. The corresponding $\Delta_f H°$(CBr, g, 298.15 K) is 122±15 kcal mol^{-1} (510.448±63 kJ mol^{-1}).

Heat Capacity and Entropy

The rotational structure of the near UV spectra of CBr(g) has been investigated by Dixon and Kroto (1) in the 3000 Å region. They assigned the above doublet electronic levels to the ground ($^2\Pi$) and first excited ($^2\Delta$) states and reported a value of B_0 = 0.4872±0.0003 cm^{-1} for the ground state. An additional electronic level ($^2\Sigma$) is expected to be close to the first excited state by analogy with CF(g) and CCl(g).

The fundamental vibrational frequency ω_e is estimated from Guggenheimer's relation for single bonded molecules (3). The anharmonic vibrational term $\omega_e x_e$ is estimated by assuming $\omega_e x_e = \omega_e^2/(4D_0 + 2\omega_e)$. The value of α_e is calculated from the Morse potential function. The rotational constant B_e is calculated from $B_e = B_0 + \alpha_e/2$. The bond distance is calculated from B_e.

Bond Angle: F-C-F = 108.6 ± 1° F-C-Br = 110.33°
Product of the Moments of Inertia: $I_A I_B I_C = 2.340709 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the enthalpies of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Coomber and Whittle (2, 3, 4) have determined equilibrium data for $CClF_3(g) + BrCl(g) = CBrF_3(g) + Cl_2(g)$ and for $CF_3X(g) + Br_2(g) = CF_3Br(g) + BrX(g)$ where X = H, Cl, and CF . Equilibrium data for $CF_3I(g) + BrI(g) = CBrF_3(g) + I_2(g)$ were obtained by Lord et al. (5). These data link $CBrF_3$ with C_2F_6, CHF_3, $CClF_3$ and CF_3I.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Sharbaugh et al. (6), Bowen (7), and Anderson (8) and from microwave data by Sheridan and Gordy (9). The adoped parameters are an average of those reported by (8, 9). Infrared spectra of the gas were observed by several investigators (10, 11, 12) and Raman spectra of the liquid were obtained by Edgell and May (12). The vibrational assignments of (11, 12) are in close agreement. These assignments are adopted but preference is given to frequencies observed for the gas. The value for ν_6 is taken as 300 cm^{-1} which is between the values of 305 and 297 ± 3 cm^{-1} derived from Raman spectra and IR (combination and overtone) spectra, respectively.

The thermodynamic functions of this table are essentially the same as those calculated by (11). Uncertainty in the entropy is estimated to vary from 0.12 to 0.5 cal/(K mol) over the range from 300 to 1000 K. Uncertainty in ν_6 and neglect of anharmonicity are the major sources of error. Discussions of the magnitude of anharmonic effects appear on the tables for $CClF_3(g)$ and $CF_4(g)$. The principal moments of inertia are: $I_A = 14.6768 \times 10^{-39}$ and $I_B = I_C = 39.9354 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: $C_{\infty V}$

Bond Distances: C-Br = 1.789 Å C-N = 1.158 Å

Bond Angle: Br-C-N = 180°

Rotational Constants: $B_0 = 0.137172\ cm^{-1}$ $D_0 = 2.929 \times 10^{-8}\ cm^{-1}$

Spectroscopic constants used in calculating corrections to rigid-rotator-harmonic oscillator approximation (cm^{-1}).

$\alpha_1 = 5.17 \times 10^{-4}$ $x_{11} = [-3.0]$ $x_{12} = [-4.0]$

$\alpha_2 = -3.84 \times 10^{-4}$ $x_{22} = -0.86$ $x_{23} = -6.19$

$\alpha_3 = 6.77 \times 10^{-4}$ $x_{33} = [-5.0]$ $x_{13} = [-3.0]$

$g_{22} = 1.14$

Enthalpy of Formation

The enthalpy of formation is calculated from $\Delta_f H°(BrCN, cr, 298.15\ K) = 33.58\ kcal\ mol^{-1}$ (1) and $\Delta_{sub} H°(298.15\ K) = 10.92 \pm 0.1\ kcal\ mol^{-1}$. This latter is obtained from an anlysis of the vapor pressure data of Lord and Woof (2) and Baxter et al. (3).

The enthalpy of formation of the crystal is calculated from $\Delta_r H°(298.15\ K) = -56.0\ kcal\ mol^{-1}$ obtained by Lord and Woolf (2) for the reaction

$$BrCN(cr) + 2NaOH(56\ H_2O) = NaCNO(2800\ H_2O) + NaBr(2800\ H_2O) + H_2O(\ell).$$

The auxiliary data used were $\Delta_f H°(NaOH.56\ H_2O, 298.15\ K) = -112.26\ kcal\ mol^{-1}$ (1, 4), $\Delta_f H(NaCNO{\cdot}2800\ H_2O, 298.15\ K) = -92.25\ kcal\ mol^{-1}$ (1, 4) and $\Delta_f H°(NaBr{\cdot}2800\ H_2O, 298.15\ K) = -70.54\ kcal\ mol^{-1}$ (1, 4). The uncertainty in the final value reflects the uncertainty in $\Delta_f H(NaCNO{\cdot}2800\ H_2O)$ which was determined by Lord and Woolf (2) to be $-93.6\ kcal\ mol^{-1}$ in excess NaOH·56 H_2O.

Heat Capacity and Entropy

Gordon (5) used the constants given above to calculate the adopted table, using the method of Pennington and Kobe (6) for anharmonicity, vibration rotation interaction, and centrifugal stretching corrections.

The bond lengths and angle were reported by Tyler and Sheridan (7).

TETRABROMOMETHANE (CBr_4) IDEAL GAS M_r = 331.627

$S°(298.15\ K) = 358.095\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [79.890]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [50.208]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
267.2(1)	670.7(3)
122.5(2)	182.5(3)

Ground State Quantum Weight: [1] σ = 12
Point Group: T_d
Bond Distance: C-Br = 1.942 Å
Bond Angle: Br-C-Br = 109° 28'
Product of the Moments of Inertia: $I_A I_B I_C = 2.376154 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was calculated and reported by Rossini et al. (1).

Heat Capacity and Entropy

The molecular constants, bond distance, and bond angle were determined by electron diffraction by Finbak et al. (2, 3). The constants reported by Finbak et al. (3) in 1943 were selected. These constants are listed in "Tables of Interatomic Distances and Configuration in Molecules and Ions," Special Publication No. 11, The Chemical Society (London), 1958. The principal moments of inertia calculated from these constants are: $I_A = I_B = I_C = 133.4417 \times 10^{-39}\ g\ cm^2$.

The vibrational frequencies used were assigned by Meister et al. (4). They measured the infrared and Raman spectrum, considered the previous literature, calculated force constants and made most probable value assignments for the frequencies. A more recent paper by Moszynska and Mathieu (5) made assignments from Raman and infrared spectra which agreed with all of Meister et al's. (4) assignments except for ν_2 which they found was 126 cm^{-1} rather than 122 cm^{-1}.

Enthalpy of Formation

The data of Miller and Palmer (1) provide a value of $D_0{}^0(CCl) = 80 \pm 5$ kcal mol^{-1}, which appears to be reasonably substantiated. They studied the chemiluminescence from flames of $CHCl_3$ and CCl_4 burning in potassium vapor. These flames exhibit C_2 Swan band radiation with major departures from vibrational and rotational equilibrium. The spectra are interpreted as due to the reaction $C + CCl \rightarrow C_2 + Cl$ where the carbon atom is either ^3D ground state or ^1D first excited state. The separation between the ground and first excited state of the carbon atom is matched closely by the difference in preferential population of the excited C_2 levels. The assumption is made that all the exothermicity of the reaction is retained as vibrational excitation of the C_2, thus the populated levels are measures of the heat of reaction. In this manner we obtain a heat of reaction of 67±2.5 kcal for the reaction $C + CCl \rightarrow C_2 + Cl$ which, using JANAF auxiliary data, gives $\Delta_f H°(CCl, g) = 124 \pm 2.5$ kcal mol^{-1}; however, this represents the initial state of the CCl which in the flame is presumed to have about 4 kcal of vibrational energy at roughly 2000 K. Thus, we obtain $\Delta_f H°(CCl, g) = 120 \pm 5$ kcal mol^{-1} (502.080±20 kJ mol^{-1}) which is adopted.

The enthalpy of formation can also be estimated from the dissociation energy calculated from the linear Birge-Sponer extrapolation of the ground state vibrational constants. This yields $D^0{}_0 = 89$ kcal or $\Delta_f H°(298.15\ K) = 111$ kcal mol^{-1}. There are several indications that this dissociation energy is probably a maximum value, for example, Hildenbrand (5) has applied an ionic-covalent correction to the linear extrapolation which gives $D^0{}_0 = 72$ kcal. We would expect this enthalpy of formation to be a minimum value. A real minimum for the dissociation energy can be obtained from the knowledge that the first vibrational level of the $^2\Delta$ state is occupied and so the dissociation energy of this state must be greater than 850 cm^{-1}. This yields a minimum dissociation energy of the ground state of 76 kcal, assuming the dissociation products are $C(^1\Delta)$ and $Cl(^2P)$, and $\Delta_f H°(CCl, g, 298.15\ K) = 124$ kcal mol^{-1} which is the maximum value of the heat of formation.

Heat Capacity and Entropy

The rotational and electronic constants are those of Verma and Mulliken (2). The vibrational constants are those derived by Ovcharenko et al. (3) from the data of Gordon and King (4). The anharmonicities listed by Verma and Mulliken are not used, since these are based only on the 0,0 and 0,1 transitions. The $^4\Sigma$ level is estimated by analogy with CF(g). The value for α_e was obtained from the other constants assuming a Morse potential function.

PREVIOUS: December 1969 (1 atm) CURRENT: December 1969 (1 bar)

CARBONIC CHLORIDE FLUORIDE (COClF) IDEAL GAS M_r = 82.461803

$S°(298.15\ K)$ = [277.012] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [-424.3 ± 33] kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [-426.8 ± 33] kJ mol^{-1}

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
776(1)	1095(1)
1868(1)	415(1)
501(1)	667(1)

Ground State Quantum Weight: 1 σ = 1

Point Group: C_s

Product of the Moments of Inertia: $I_A I_B I_C$ = 2.7911 x 10^{-114} g^3 cm^6

Enthalpy of Formation

The enthalpies of formation of $COCl_2$ and COF_2 have been averaged to obtain that of COClF.

Heat Capacity and Entropy

The molecular constants are from Lovell et al (1). The principal moments of inertia are: I_A = 7.480 x 10^{-39}, I_B = 16.008 x 10^{-39} and I_C = 23.31 x 10^{-39} g cm^2.

Bond Angles: F-C-F = 108.6 ± 0.5° F-C-Cl = 110.33°
Product of the Moments of Inertia: $I_A I_B I_C = 9.444771 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Coomber and Whittle (2) have determined equilibrium data for $CClF_3(g) + BrX(g) = CBrF_3(g) + ClX(g)$ where X = Cl and Br. Lord et al. (3) studied the *analogous equilibria* $CF_3I(g) + ClI(g) = CClF_3(g) + I_2(g)$. *These data link* $CClF_3$ *with* $CBrF_3$ *and* CF_3I.

Other data which were omitted from the adjustment include those of Baibuz (4, 5), Mears (6), Kolesov (7), Kirkbride (8), and von Wartenberg (9). Baibuz (4, 5) derived $\Delta_f H° = -166.2 \pm 2.2$ kcal mol^{-1} by applying the method of explosion in a spherical bomb to mixtures of H_2, O_2 and $CClF_3$. By comparison with similar data for CF_4 and CCl_4, we estimate the bias in Baibuz' value to be about +2 kcal mol^{-1}. Mears (6) gave a preliminary report of values of $\Delta_r H$ at 300°C for reactions involving HF, HCl and CCl_nF_{4-n} (n = 1, 2, 3, 4). We derive $\Delta_f H°$ = -172 and -173 kcal mol^{-1} from two different combinations of reactions; however, no detailed account of the data has been published. The other authors (7, 8, 9) measured $\Delta_r H$ for reaction of $CClF_3$ with an alkali metal (Na or K) to form amorphous carbon and mixtures of the fluoride and chloride. Discrepancies of many kcal mol^{-1} exist in these studies, presumably due to inadequate characterization of the thermochemical reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Bowen (10) and Bartell (11). Results from Bartell are adopted. These parameters are consistent with the microwave data of Coles (12). The principal moments of inertia are: $I_A = 14.6768 \times 10^{-39}$ and $I_B = I_C = 25.3677 \times 10^{-39}\ g\ cm^2$. Vibrational assignments are based on the work of Claassen (13) and the gas-phase Raman spectra observed by Holzer and Moser (14).

The largest uncertainty in $C_p°$ *and* $S°$ *probably results from the neglect of anharmonicity.* Barho (15) and Albright (16) have given estimates for the anharmonic contributions. These vary from 0.1 to 0.3 cal $K^{-1}\ mol^{-1}$ in both $C_p°$ and $S°$ over the range from 300 to 1000 K, respectively. Somewhat larger contributions are possible based on the anharmonic functions calculated by McBride (17) for $CF_4(g)$. *We estimate the overall uncertainty in the entropy of this JANAF table to be 0.1 cal* $K^{-1}\ mol^{-1}$ at 300 K and 0.4 cal $K^{-1}\ mol^{-1}$ at 1000 K. $C_p°$ is consistent with $C_v°$ measured at 300 K by the wire-ribbon method (18).

Enthalpy of Formation

The enthalpy of formation was taken from Wagman et al. (1).

Heat Capacity and Entropy

Gordon (2) has used the constants listed above to calculate C_p from 298.15 to 6000 K using the method of Pennington and Kobe (3) which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants B_o and D_o were taken from Burrus and Gordy (4), ω_1, x_1, x_3, x_{22}, x_{23}, x_{13}, and g_{22} were obtained from Lafferty et al. (5), α_2 has been taken from Townes et al. (6) and x_{11}, x_{33} and x_{12} were estimated by Gordon (2). The bond distances and bond angle were taken from Lafferty et al. (5).

$S°(298.15\ K) = [265.965]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-64.3 \pm 42]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [-62.8 \pm 42]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
570 (1)
281 (1)
1880 (1)

Ground State Quantum Weight: 2 $\sigma = 1$

Point Group: C_s

Bond Distance: C-Cl = [1.75] Å C-O = [1.17] Å

Bond Angle: Cl-C-O = [120]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.276664 \times 10^{-115}]\ g^3\ cm^6$

Enthaply of Formation

The enthalpy change ($\Delta_r H°$) for the reaction $COCl_2(g) = CO(g) + 2Cl(g)$ is calculated to be 82 kcal mol^{-1}, which is the sum of two bond energies, i.e. D(Cl-COCl) + D(Cl-CO). By comparison with values, $D(H_3C\text{-}COCH_3)/D(H_3C\text{-}CO) = 72/18 = 4.0$ for CH_3COCH_3 (g) and $D(H_3C\text{-}COCl)/D(Cl\text{-}CO) = 4.3$ for $CH_3COCl(g)$, the ratio of D(Cl-COCl)/D(Cl-CO) is estimated to be 4.0 for $COCl_2(g)$. Hence the enthalpy change for the reaction $COCl_2(g) = COCl(g) + Cl(g)$ is calculated as 82 x (4/5) = 65.6 kcal mol^{-1}. Using the $\Delta_r H°$ value obtained, the enthalpy of formation for COCl(g) is derived to be -15±10 kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational frequencies were reported by Jacox and Milligan (1). The bond distances and angle were estimated by Jacox and Milligan (1). Due to the presence of one unpaired electron on C atom, the ground state quantum weight is calculated to be 2. The principal moments of inertia are: $I_A = 0.7159 \times 10^{-39}$, $I_B = 13.0005 \times 10^{-39}$, and $I_C = 13.7165 \times 10^{-39}\ g\ cm^2$.

Point Group: C_{2v} $\sigma = 2$
Bond Distance: C-Cl = [1.76] Å
Bond Angle: Cl-C-Cl = [100 ± 10]°
Product of the Moments of Inertia: $I_A I_B I_C = [1.101940 \times 10^{-114}]\ g^3\ cm^6$

Enthalpy of Formation

Shapiro and Lossing (1) have measured mass-spectrometrically the appearance potentials 12.2 and 14.7 eV for the processes $CHCl_3(g) + e^- \rightarrow CCl_2^+(g) + HCl(g) + 2e^-$ and $C_2Cl_4(g) + e^- \rightarrow CCl_2^+(g) + CCl_2(g) + 2e^-$, respectively. The difference in these two processes gives $\Delta_r H° = 2.5$ eV (57.65 kcal mol^{-1}), for the reaction $C_2Cl_4(g) + HCl(g) \rightarrow CCl_2(g) + CHCl_3(g)$ which leads to $\Delta_f H°(CCl_2, g, 298.15\ K) = 57.32$ kcal mol^{-1}, using $\Delta_f H°(298.15\ K) = -2.97$, -22.063 and -24.7 kcal mol^{-1} for $C_2Cl_4(g)$, HCl(g) and $CHCl_3(g)$, respectively. Since the authors claimed that the experimental error was probably 5 kcal mol^{-1}, the value 57±5 kcal mol^{-1} (238.488±21 kJ mol^{-1}), is adopted for the enthalpy of formation.

Heat Capacity and Entropy

Milligan and Jacox (2) have found two stretching fundamentals (721 and 748 cm^{-1}) for the CCl_2 radical in the infrared and ultraviolet spectra by matrix-isolation, and proposed a bent molecular structure (the valence angle = 100 ± 10°) with a ground singlet state which was based on the analogy with the electronic absorption spectrum of CF_2. L. Andrews (3) has confirmed all these observations in his infrared spectrometric studies of dichlorocarbene in solid argon, and made vibrational assignment to the fundamentals and also eliminated the possibility of a linear molecular structure for CCl_2. The bending frequency (350 cm^{-1}) is estimated by the valence force method (4), using the same ratio of bending over stretching force constants from $CF_2(g)$ (5). The bond distance is estimated to be the same as that of $CCl_4(g)$ measured by Bartell et al. (6). The principal moments of inertia are $I_A = 2.1829 \times 10^{-39}$, $I_B = 21.4029 \times 10^{-39}$, and $I_C = 23.5858 \times 10^{-39}$ g cm^2.

The triplet low lying electronic level of 4000 cm^{-1} is estimated by analogy with that of $CF_2(g)$. The other level of 17,5000 cm^{-1} is also estimated based on a weak band appearing between 4400 and 5600 Å in the spectra of CCl_2 observed by Milligan and Jacox (2).

Enthalpy of Formation

Mears and Stahl (1) investigated several heats of reaction involving CF_4, CF_3Cl, CF_2Cl_2, $CFCl_3$, CCl_4, HF and HCl. Using JANAF values for all compounds except CF_2Cl_2 and $CFCl_3$ we obtain the following observations:

1. $\Delta_f H°(CCl_3F, g, 298.15\ K) = -70.12 \pm 1.1\ kcal\ mol^{-1}$
2. $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -116.53 \pm 1.5\ kcal\ mol^{-1}$
3. $\Delta_f H°(CCl_2F_2, g, 298.15\ K) - \Delta_f H°(CCl_3F, g, 298.15\ K) = -49.39 \pm 1.0\ kcal\ mol^{-1}$
4. $\Delta_f H°(CCl_2F_2, g, 298.15\ K) - 2\ \Delta_f H°(CCl_3F, g, 298.15\ K) = 20.34 \pm 1.0\ kcal\ mol^{-1}$
5. $\Delta_f H°(CCl_3F, g, 298.15\ K) - 2\ \Delta_f H°(CCl_2F_2, g, 298.15\ K) = 165.47 \pm 1.0\ kcal\ mol^{-1}$

The sum of the squares of the deviations is smallest when $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -117.5\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_3F, g, 298.15\ K) = -69\ kcal\ mol^{-1}$, and all the values are within their uncertainty ranges.

Peterson and Pitzer (8) obtained an approximate equilibrium constant for the reaction $2\ CClF_3(g) + CCl_4(g) = 3\ CCl_2F_2(g)$ of $\log K_{400} = -3.0$. This on 3rd law reaction gives $\Delta_r H°(298.15\ K) = 7.64\ kcal\ mol^{-1}$ and with $\Delta_f H°(CClF_3, g, 298.15\ K) = -169.2\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_4, g, 298.15\ K) = -22.94\ kcal\ mol^{-1}$ this yields $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -117.9\ kcal\ mol^{-1}$.

Kirkbride and Davidson (2) investigated the reaction of potassium with the chlorofluoromethanes and obtained $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -115.1 \pm 2\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_3F, g, 298.15\ K) = -72.9 \pm 4\ kcal\ mol^{-1}$ after correction with JANAF auxiliary data. Wartenberg and Schiefer (3) investigated the same reaction and we obtain, after correction with JANAF auxiliary data, $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -112.7\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_3F, g, 298.15\ K) = -63.1\ kcal\ mol^{-1}$. Kolesov et al (4) have reported analogous data for the reaction with sodium which, after correction with JANAF auxiliary data, yields $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -114.4 \pm 3.5\ kcal\ mol^{-1}$.

We adopt the values calculated above from Mears and Stahl (1), since they have a high degree of internal consistency and also lead to a realistic progression in the heats of atomization in going from CF_4 to CCl_4. With the adopted heats of formation, the successive replacement of F by Cl changes the atomization heats by 43.8, 41.6, 38.5, and 36.0 kcal.

Heat Capacity and Entropy

Claassen (5) chose the frequencies given above from his own gas-phase Raman measurements and the infrared values of earlier investigators. The values are in good agreement with the assignment of Plyler and Benedict (6). Masi (9) has measured the gas phase heat capacities at 243, 273, 318 and 363 K, within this range our adopted heat capacities are from .3 to .7% high. The entropies agree to within 0.05% and further adjustment to obtain better fits was not considered necessary. The molecular structure was determined from the microwave measurements of Long et al. (7). The principal moments of inertia are: $I_A = 21.0747 \times 10^{-39}$, $I_B = 31.7398 \times 10^{-39}$, and $I_C = 37.9277 \times 10^{-39}\ g\ cm^2$.

Point Group: C_{2v} $\sigma = 2$

Bond Distances: C-O = 1.166±0.002 Cl-O = 2.589±0.001 Cl-Cl = 2.884±0.001 C-Cl = 1.746±0.004

Bond Angle: Cl-C-Cl = 111.3±0.1°

Product of the Moments of Inertia: $I_A\ I_B\ I_C = 9.138289 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

Thomsen (1) reports the enthaply of alkaline hydrolysis of $COCl_2$, from which $\Delta_f H°(298.15\ K)$ is calculated to be -54.4±0.3 kcal mol^{-1}. From the enthalpy of combustion of $COCl_2$ in O_2 and H_2, reported by Thomsen (2), $\Delta_f H°(298.15\ K)$ is calculated to be -51.73 ± 0.43 kcal mol^{-1}. Bodenstein and Plaut (3), Christiansen (4), and Bodenstein and Dunant (5) report 10 values of K_p from 647 to 876 K for the reaction $CO + Cl_2 = COCl_2$. These yield -25.91±0.04 kcal for $\Delta_f H°(298.15\ K)$ for $COCl_2$ is -52.33±0.62 kcal mol^{-1}. The average of the 3 foregoing values of $\Delta_f H°(298.15\ K)$ weighted for the uncertainties, is adopted here. Values calculated from the degree of dissociation of $COCl_2$ from 374 to 778 K, reported by Atkinson, et al. (6), range from -47.06 to -53.11 kcal mol^{-1} and are ignored.

Heat Capacity and Entropy

The vibrational frequencies were assigned by Catalano and Pitzer (7), on the basis of their own infra-red spectra and other data. The molecular dimensions listed above were deduced from microwave spectra by Robinson (8), and are confirmed by electron-diffraction values compiled by Allen and Sutton (9). The moments of inertia are weighted for the isotopes and were calculated from Robinson's dimensions by Giauque and Ott (10). Giauque and Ott (10) determined S°(298.15 K) experimentally to be 67.81 cal K^{-1} mol^{-1}, with which the value calculated here agrees, i.e. 67.816 cal K^{-1} mol^{-1}. The principal moments of inertia are: $I_A = 10.6393 \times 10^{-39}$, $I_B = 24.4666 \times 10^{-39}$, and $I_C = 35.1059 \times 10^{39}$ g cm^2.

Bond Distance: C-Cl = [1.74]Å
Bond Angle: Cl-C-Cl = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [3.822311 \times 10^{-113}]\ g^3\ cm^6$

Enthalpy of Formation

Benson (1) has reanalysed the kinetic data of Sullivan and Davidson (2) for the reaction $Br_2(g) + CHCl_3(g) = HBr(g) + CBrCl_3(g)$ and has obtained from it the enthalpy of the initial step, $Br(g) + CHCl_3(g) \rightarrow CCl_3(g) + HBr(g)$, as 8.2 ± 1 kcal mol^{-1}. Substituting this value and $\Delta_f H°(Br, g, 298.15\ K) = 26.74\ kcal\ mol^{-1}$, $\Delta_f H°(CHCl_3, g, 298.15\ K) = -24.66\ kcal\ mol^{-1}$ and $\Delta_f H°(HBr, g, 298.15\ K) = -8.71\ kcal\ mol^{-1}$, we obtain $\Delta_f H°(CCl_3, g, 298.15\ K) = 19 \pm 2\ kcal\ mol^{-1}$ (79.496 ± 8 k J mol^{-1}), which is adopted here.

Heat Capacity and Entropy

Walsh (3) has predicted that CCl_3 is non-planar on the basis of his orbital correlation diagram. Andrews (4) indicates that his matrix infrared observations of the symmetric and antisymmetric stretches are consistent with a non-planar C_{3v} structure and a near tetrahedral angle. The antisymmetric stretch has been confirmed by Current and Burdett (5). They rationalize the absence of the symmetric stretch and claim support of the C_{3v} structure. Rogers et al. (6) have made a thorough search for the symmetric stretch and did not find it in the region where is was reported by Andrews (4). Thus, they conclude that since only the antisymmetric stretch has been confirmed, the possibility of a planar D_{3h} molecule cannot be excluded. Maget et al. (7) have observed the NMR spectrum of trapped CCl_3 and find it consistent with a planar molecule. The absence of the symmetric stretch strongly implies a planar configuration, and we adopt such a configuration until more definitive proof of the non-planarity can be obtained. The remaining vibrational frequencies are estimated by comparison with those of BCl_3. The bond length was estimated as 1.74 Å by Andrews (4) from a correlation with related molecules. The principal moments of inertia are: $I_A = I_B = 26.7361 \times 10^{-39}$ and $I_C = 53.4723 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

Mears and Stahl (1) investigated several enthalpiess of reaction involving CF_4, CF_3Cl, CF_2Cl_2, $CFCl_3$, CCl_4, HF and HCl. Using JANAF values for all compounds except CF_2Cl_2 and $CFCl_3$, we obtain the following observations:

1. $\Delta_f H°(CCl_3F, g, 298.15\ K) = -70.12 \pm 1.1\ kcal\ mol^{-1}$
2. $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -116.53 \pm 1.5\ kcal\ mol^{-1}$
3. $\Delta_f H°(CCl_2F_2, g, 298.15\ K) - \Delta_f H°(CCl_3F, g, 298.15\ K) = -49.39 \pm 1.0\ kcal\ mol^{-1}$
4. $\Delta_f H°(CCl_2F_2, g, 298.15\ K) - 2\Delta_f H°(CCl_3F, g, 298.15\ K) = 20.34 \pm 1.0\ kcal\ mol^{-1}$
5. $\Delta_f H°(CCl_3F, g, 298.15\ K) - 2\Delta_f H°(CCl_2F_2, g, 298.15\ K) = 165.47 \pm 1.0\ kcal\ mol^{-1}$

The sum of the squares of the deviations is smallest when $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -117.5\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_3F, g, 298.15\ K) = -69\ kcal\ mol^{-1}$, and all the values are within their uncertainty ranges.

Petersen and Pitzer (9) obtained an approximate equilibrium constant for the reaction $CClF_3(g) + 2CCl_4(g) = 3CCl_3F(g)$ of $\log K_{400} = -4.5$. This on third law reduction gives $\Delta_r H°(298.15\ K) = 10.56$ kcal and with $\Delta_f H°(CClF_3, g, 298.15\ K) = -169.2\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_4, g, 298.15\ K) = -22.94\ kcal\ mol^{-1}$ this yields $\Delta_f H°(CCl3F, g, 298.15\ K) = -68.2\ kcal\ mol^{-1}$.

Kirkbride and Davidson (2) investigated the reaction of potassium with the chlorofluoromethanes and obtained $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -115.1 \pm 2\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_3F, g, 298.15\ K) = -72.9 \pm 4\ kcal\ mol^{-1}$ after correction with JANAF auxiliary data. Wartenberg and Schiefer (3) investigated the same reaction and we obtain, after correction with JANAF auxiliary data, $\Delta_f H°(CCl_2F_2, g, 298.15\ K) = -112.7\ kcal\ mol^{-1}$ and $\Delta_f H°(CCl_3F, g, 298.15\ K) = -63.1\ kcal\ mol^{-1}$. Baibuz (4) has reported $\Delta_f H°(CCl_3F, g, 298.15\ K) = -66.4 \pm 2.1$ from heat of explosion measurements. A correlation of his other results would indicate that this value is not negative enough, possibly by as much as 3 kcal.

We adopt the values calculated above from Mears and Stahl (1), since they have a high degree of internal consistency and also lead to a realistic progression in the heats of atomization in going from CF_4 to CCl_4. With the adopted enthalpies of formation, the successive replacement of F by Cl changes the atomization enthalpies by 43.8, 41.6, 38.5 and 36.0 kcal.

Heat Capacity and Entropy

Claassen (5) chose the frequencies given above from his own gas phase Raman measurements and the infrared values of earlier investigators. The values are in good agreement with the assignment of Plyler and Benedict (6), and the matrix studies of King (7). The molecular structure was determined from the microwave measurements of Long et al. (8). The principal moments of inertia are: $I_A = I_B = 34.3029 \times 10^{-39}$ and $I_C = 48.7471 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: T_d
Bond Distance: C-Cl = 1.760 Å
Bond Angle: Cl-C-Cl = 109.47°
Product of the Moments of Inertia: $I_A I_B I_C = 1.150034 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

Hu and Sinke (1) have measured the enthalpy of combustion of $CCl_4(\ell)$ in the rotating platinum bomb calorimeter, using As_2O_3 solution as the reducing agent. They reported $\Delta_c H°(298.15\ K) = -86.02$ kcal mol^{-1} for $CCl_4(\ell) + 2H_2O(\ell) + CO_2(g) + 4HCl(600H_2O, aq)$ which leads to $\Delta_f H°(CCl_4, \ell, 298.15\ K) = -30.69$ kcal mol^{-1}, using $\Delta_f H°(298.15\ K) = -94.051$, -39.823 and -68.315 kcal mol^{-1} for $CO_2(g)$, $HCl(600H_2O, aq)$ and $H_2O(\ell)$, respectively (2). The standard deviation of five combustion runs was ±0.074 kcal mol^{-1}. Employing the enthalpy of vaporization of $CCl_4(\ell)$ at 298.15 K as 7.75 kcal mol^{-1} (3), we obtain $\Delta_f H°(CCl_4, g, 298.15K) = -22.94$ kcal mol^{-1} which is adopted in the tabulation.

Smith et al. (5), based on the combustion data of Eftring (4), re-evaluatd the enthalpy of combustion of carbon tetrachloride at 18.7°C as $\Delta_c E°/M = -567.5$ cal/g for $CCl_4(\ell) + 2H_2O(\ell) + CO_2(g) + 4HCl(600H_2O)$. This value needs to be further corrected for a change in the heat of oxidation of As_2O_3 (6) and calculated to 25°C to give $\Delta_c E°(298.15\ K) = -88.105$ kcal mol^{-1}. $\Delta_c H°(298.15\ K) = -87.513$ kcal mol^{-1}, $\Delta_f H°(CCl_4, \ell, 298.15\ K) = -29.20$ kcal mol^{-1} and $\Delta_f H°(CCl_4, g, 298.15\ K) = -21.45$ kcal mol^{-1}.

Neugebauer (7) has measured the enthalpy of reaction of CCl_4 with Mg in presence of hydrogen in the stationary bomb calorimeter and then derived the enthalpy of formation, $\Delta_f H°(CCl_4, \ell, 298.15\ K) = -32.3 \pm 2$ kcal mol^{-1} which yields $\Delta_f H°(CCl_4, g, 298.15\ K) = -24.55 \pm 2$ kcal mol^{-1}. Baibuz (8), using an explosion technique, obtained $\Delta_f H°(CCl_4, g, 298.15\ K) = -24.6 \pm 1.9$ kcal mol^{-1}. Bodenstein and Gunther (9) have measured calorimetrically $\Delta_r H°(293\ K) = -62.57 \pm 0.35$ kcal mol^{-1} for $CCl_4(g) + 2H_2(g) \rightarrow C(cr) + 4HCl(g)$. They calibrated their calorimeter by means of the reaction $H_2(g) + Cl_2(g) \rightarrow 2HCl(g)$ for which they took $\Delta_f H°(293\ K) = -44$ kcal mol^{-1}. Their data have been re-evaluated to give $\Delta_f H°(CCl_4, g, 298.15\ K) = -25.68$ kcal mol^{-1}, but no correction is applied for the enthalpy of formation of carbon which was not the reference state "graphite" formed in the reaction. Domalski and Armstrong (10) reviewed several cases of active carbon formed in similar reactions and quoted a *enthalpy of formation of carbon from +1.9 to +3.95* kcal mol^{-1}. If this correction is applied to the data of Bodenstein, their enthalpy of formation of $CCl_4(g)$ should be 2 to 4 kcal mol^{-1} less negative than -25.68 kcal mol^{-1}.

Heat Capacity and Entropy

Bartell, Brockway and Schwendeman (11) have measured the bond distance as 1.760 ± 0.004 Å by the electron diffrction measurement. The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (12) in which they are essentially the same as those frequencies determined from Raman and infrared spectra by Classen (13). The principal moments of inertia are $I_A = I_B = I_C = 48.6299 \times 10^{-39}\ g\ cm^2$.

COPPER CYANIDE (CuCN) CRYSTAL M_r = 89.5637

$S°(298.15\ K) = 90.002 \pm 0.25\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 746\ K$

$\Delta_f H°(0\ K) = 93.32 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 94.98 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 12 \pm 4\ kJ\ mol^{-1}$

Enthalpy of Formation

Taylor, Brown and Taylor (1) determined by solution calorimetry the enthalpy of reaction, $\Delta_r H°(298.15\ K) = -13.437 \pm 100$ cal $K^{-1} mol^{-1}$ for NaCN(cr) + 0.5 Cu_2O(cr) + 0.5 H_2O(ℓ) + CuCN(cr) + NaOH(128.5 H_2O). This leads to $\Delta_f H°$(CuCN, cr, 298.15 K) = 22.70±0.5 kcal mol^{-1} using the following auxiliary data: $\Delta_f H°$(NaCN, cr, 298.15 K) = -21.68±0.3 kcal mol^{-1} (2), $\Delta_f H°$(Cu_2O, cr, 298.15 K) = -40.7±0.5 kcal mol^{-1} (3), $\Delta_f H°$(H_2O, ℓ, 298.15 K) = -68.315 kcal mol^{-1} (4) and $\Delta_f H°$(NaOH · 128.5 H_2O, aq, 298.15 K) = -112.321 kcal mol^{-1} (2, 4).

Heat Capacity and Entropy

The heat capacity of CuCN(cr) has been measured adiabatically over the temperature range from 8 to 402 K by Taylor, Brown and Taylor (1). The smooth $C_p°$ values are adopted in the tabulation. The value of S°(298.15 K) is calculated from the $C_p°$ data and is based on an extrapolation of S°(8 K) = 0.104 cal K^{-1} mol^{-1}. They also found an anomaly in the heat capacity at 300 K which is considered as a second order phase transition. Heat capacities above 402 K are estimated by extrapolation of the measured $C_p°$ data.

Fusion Data

The melting point 746 K was determined by Truthe (5). The heat of melting is calculated from the phase diagram studies of KCN - CuCN and NaCN - CuCN reported by Truthe (5).

Enthalpy of Formation

Faber et al. (1) have studied the weight change of graphite in CF_4 at high temperatures. Our reanalysis of their data use the equilibrium constants for CF_4, CF_3 and CF_2 from the JANAF Tables (2); the only other C-F species considered is assumed to be CF. This treatment yields negative values for the CF pressure except at the highest temperature, where 3rd law analysis of the equilibrium constant yields $\Delta_f H°(CF, g, 298.15\ K) = 59.4\ kcal\ mol^{-1}$. Farber et al. (1) also investigated mass-spectrometrically the vapor species present at equilibrium and followed the intensities of CF^+ and F^+. From a 2nd law treatment of the intensities they report $\Delta_f H°(CF, g, 2300\ K) = 62.0\ kcal\ mol^{-1}$, or $\Delta_f H°(CF, g, 298.15\ K) = 64\ kcal\ mol^{-1}$.

Porter et al. (3) have investigated the A-X band system under high dispersion. From an analytical extrapolation of the 10 observed levels they reported a dissociation energy of 126.9±2.9 kcal mol^{-1}, which yields $\Delta_f H°(CF, g, 298.15\ K) = 61.9 \pm 2.9\ kcal\ mol^{-1}$.

The predissociation limit of CF(g) has been reported by Thrush and Zwolenik (4) as <132 kcal mol^{-1}; Kuzyakov and Tatievsky (5) determined the same quantity as <133 kcal mol^{-1}. These results yield $\Delta_f H°(CF, g, 298.15\ K) > 56\ kcal\ mol^{-1}$. Thrush and Zwolenik (4) also report a predissociation limit for the reaction $CF_2 \rightarrow CF + F$ which is <120 kcal mol^{-1}. This value has now been shown to be erroneous (see the CF_2(g) table for details).

Modica (6) has studied the equilibrium $CF_2 \rightarrow CF + F$ in a shock tube in the range 2680 to 3400 K. Since functions for CF_2, CF and F are well established, the data were analyzed using 2nd and 3rd law treatments. The 2nd law analysis gives $\Delta_r H°(298.15\ K) = 107.2 \pm 7.6\ kcal\ mol^{-1}$, in agreement with with value reported by Modica. The 3rd law analysis yields $\Delta_r H°(298.15\ K) = 134.9 \pm 7.2\ kcal\ mol^{-1}$ and a drift of $9.7 \pm 2.5\ cal\ K^{-1}\ mol^{-1}$. The excessive drift indicates that the reported equilibrium constants do not represent the stated reaction.

Andrews and Barrow (7) report a dissociation energy of 114 kcal from an extrapolation of four B state levels. This extrapolation is considered unreliable by Porter et al. (3) since this state is formed from an avoided crossing and is likely to be perturbed.

The adopted value of $\Delta_f H°(CF, g, 298.15\ K)$ is 61±2 kcal mol^{-1} (255.224±8 kJ mol^{-1}), which is within the uncertainties and ranges of the acceptable investigations.

Heat Capacity and Entropy

The vibrational and rotational constants are from Porter et al. (3); the higher electronic levels are those reported by Andrews and Barrow (7), except that the B state is now considered to be $^2\Sigma$. The estimated level at 25000 cm^{-1} is proposed in order to explain the low bond dissociation energy of C_2F_2, by analogy with the reasoning used by Simons [8] for C_2F_4. This level would be a $^4\Sigma$ level and could correlate with the ground state atoms.

ω_e = [1380] cm^{-1} $\omega_e x_e$ = [11.6] cm^{-1} σ = 1
B_e = [1.4361] cm^{-1} α_e = [0.0193] cm^{-1} r_e = [1.263] Å

Enthalpy of Formation

There have been no direct determinations of the ionization potential but Johns and Barrow (1) have calculated a value by assuming the $B^2\Sigma^+$ state of CF to be the first of a Rydberg series. They report IP = 8.91 eV (205.464 $kcal^{-1}$) which yields $\Delta_f H°(CF^+, g, 0\ K)$ = 265.6 ± 10 kcal mol^{-1}. An identical value has been calculated by Carroll and Grennan (7) who assumed the $A^2\Sigma^+$ state of CF to be the start of a Rydberg series and estimated the termination by comparison with the same series in N_2, CO and NO.

Diebler and Liston (2) have measured the photoionization onset of the process FCN + hν → CF^+ + N + e^1 ($\Delta H°(0\ K)$ = 377.03 kcal mol^{-1}). Using JANAF auxiliary data (3), we obtain $\Delta_f H°(CF^+, g, 0\ K)$ = 273.0 ± 4 kcal mol^{-1}.

Walter et al. (4) have observed the photoionization onset of the process C_2F_4 + hν → CF^+ + CF_3 + e^- ($\Delta H°(0\ K)$ = 317.306 ± 0.23 kcal mol^{-1}. The JANAF values (3) for C_2F_4 and CF_3 are consistent since they are both derived from the same simultaneous solution, they yield $\Delta_f H°(CF^+, g, 0\ K)$ = 272.464 ± 1.2 kcal mol^{-1}(1139.989 ± 5.0 kJ mol^{-1}), which is adopted. This corresponds to an ionization potential of 212.328 kcal (9.21 eV).

Heat Capacity and Entropy

Spectra reported in the literature, Verma (5), were later shown to belong to BF by Verma (6). We estimated the molecular constants by comparison with CF(g) and BF(g) (3). The $^3\Pi$ electronic level was estimated by comparison with AlCl(g) (3). The enthalpy between 0 and 298.15 K is 2.072 kcal mol^{-1}.

Rotational Constant: $B_0 = 0.353106\ cm^{-1}$

Enthalpy of Formation

Davis and Okabe (1) have determined the dissociation energy of FCN to F(g) and CN(g) by measuring the threshold energies of incident photon radiation to produce $B^2\Sigma^+$ CN which is monitored by its fluorescence. The dissociation energy determined by this technique is $\leq$ 111 kcal mol^{-1} with an uncertainty of about 1 kcal in the determination of the limit.

Dibeler and Liston (2) have reported a dissociation energy of $\leq$ 115.6 kcal mol^{-1} from the threshold of the CN^+ ion as determined by photoionization.

We adopt a median value of 113.1±2.5 kcal mol^{-1} which leads to $\Delta_f H°$(FCN, g, 298.15 K) = 8.6±4 kcal mol^{-1} (35.982±16.7 kJ mol^{-1}) with auxiliary JANAF values for F(g) and CN(g).

Heat Capacity and Entropy

The molecular structure and bond lengths and angle were determined using microwave spectroscopy by Tyler and Sheridan (3). The vibrational frequencies were reported by Aynsley et. al. (4) from the infrared spectrum, except for the bending frequency which is estimated from the values for ClCN, BrCN and ICN, by comparison of bending force constants. The reasonable limits for this value as calculated from generous limits on the bending force constant are 405-450 cm^{-1}.

PREVIOUS: June 1969 (1 atm) CURRENT: June 1969 (1 bar)

CARBONYL FLUORIDE (COF) IDEAL GAS M_r = 47.008803

$S°(298.15\ K) = [248.48]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-172.1 \pm 63]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [-171.5 \pm 63]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
1018(1)
626(1)
1855(1)

Ground State Quantum Weight: 2 $\sigma = 1$
Point Group: C_s
Bond Distances: C-F = [1.34] Å C-O = [1.18] Å
Bond Angle: F-C-O = [135]°
Product of the Moments of Inertia: $I_A I_B I_C = [2.199751 \times 10^{-116}]\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy change $\Delta_r H°$ for the reaction $COF_2(g) = CO(g) + 2F(g)$ was calculated as 160.5 kcal mol^{-1}. By analogy with $\Delta_{at}H°$(Cl-COCl, O K), $\Delta_{at}H°$(Cl-CO, O K), the value of $\Delta_{at}H°$(F-COF, O K), $\Delta_{at}H°$(F-CO, O K) was taken to be 4. Based on $\Delta_r H°$ = 160.5 x (4/5) = 128.4 kcal mol^{-1} for the reaction $COF_2(g) = COF(g) + F(g)$, the enthalpy of formation for COF(g) was derived as -41±15 kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational frequencies were reported by Milligan et al. (1). The bond distances and angle were estimated by comparison with those for HFCO(g). Due to the presence of one unpaired electron on C atom, the ground state quantum weight is calculated to be 2. The principal moments of inertia are: $I_A = 0.3399 \times 10^{-39}$, $I_B = 7.8768 \times 10^{-39}$, and $I_C = 8.2167 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

Thrush and Zwolenik (1) reported a predissociation limit for CF_2 → CF + F; however, Marsigny et al. (2) have since observed in emission the assumed predissociated level, and others above it, which invalidates the reported limit.

Walter et al. (3) have obtained the photoionization threshold at 0°K for onset of the reaction $C_2F_4 + e^- \rightarrow CF_2^+ + CF_2 + 2e^-$, as 14.63 ± 0.04 eV (337.37 kcal). The ionization potential of CF_2 has been reported as 11.7 eV (4), 11.8 ± 0.3 eV (5) and 11.86 ± 0.1 eV (6). Since these values were obtained by electron impact methods, there may be excess energy involved. Thus, adopting the lowest value as 11.7 ± 0.2 eV, we obtain $\Delta_f H°(CF_2, g, 298.15\ K) = -44.4 \pm 2.5\ kcal\ mol^{-1}$ (7). All previous electron impact methods are considered superseded by this photoionization result.

Modica and LaGraff (8) determined equilibrium constants for the reaction (A) $C_2F_4 + 2CF_2$ by use of a shock tube to achieve high temperatures and ultra violet absorption to detect the CF_2 concentration. Carlson (9) has studied the same reaction using a similar technique, and also Zmbov et al. (5) have investigated this equilibrium in a mass spectrometer. A 2nd and 3rd law analysis of all three sets of data is given below along with our recalculated equilibrium data of Farber et al. (10) for the reaction (B) C + 2F → CF_2 from weight loss experiments in the system C + CF_4.

Kinetic methods were used by Edwards and Small (11) to study the equilibrium (C) $CHF_2Cl(g) \rightleftarrows CF_2(g) + HCl(g)$. They analysed their data by assuming that the only other equilibrium occurring was $2CF_2(g) \rightleftarrows C_2F_4(g)$, and fit their kinetic data by trial and error. In this manner they obtained activation energies of the forward and back reaction (C) of 55.79 ± 0.49 and 6.21 ± 3.0 kcal, thus ΔE_a = 49.6 ± 3.0 and $\Delta H(900\ K)$ = 51.4 ± 3 kcal, which yields $\Delta_f H(CF_2, 298.15\ K) = -42 \pm 4\ kcal\ mol^{-1}$ (7). They also obtained the activation energy of reaction (A) as 70.36 ± 1.3 kcal. Dalby (12) has reported the activation energy of the reverse of (A) as 1.2 ± 0.2 kcal, thus, ΔE_a = 69.2 ± 1.3 and $\Delta H(900\ K)$ = 71.0 ± 1.3 kcal, which yields $\Delta_f H(CF_2, 298.15\ K) = -42.6 \pm 1.0\ kcal\ mol^{-1}$ (7). Gozzo and Patrick (13) also investigated the kinetics of reaction C and obtained activation energies of 51.4 ± 2.5 and 14.4 ± 5 kcal, the latter value being corrected for the activation energy of CF_2 recombination (12). Thus, we obtain ΔE_a = 37 ± 7 and $\Delta H(1000\ K)$ = 39 ± 7 kcal, which yields $\Delta_f H°(CF_2, 298.15\ K) = -54 \pm 9\ kcal\ mol^{-1}$ (7).

Modica and LaGraff (14) investigated the kinetics of CHF_3 decomposition by a mass spectrometer coupled to a shock tube. They investigated the pressure dependence of the rate and concluded that at the high pressure limit E_o = 58.4 ± 2.2 kcal. Taking this value as $\Delta H°(0\ K)$ for the reaction (D) $CHF_3(g) \rightarrow CF_2(g) + HF(g)$, we obtain $\Delta_f H°(CF_2, 298.15\ K) = -41.3 \pm 2.5\ kcal\ mol^{-1}$ (7). However, any activation energy of the reverse reaction (D) will make this value more negative. Since values of the reverse activation energy of analogous reaction (C) range from 6.2 to 14.4 kcal, it appears likely that reverse reaction (D) will have a significant activation energy; thus, $\Delta_f H(CF_2, 298.15\ K) < -41.3 \pm 2.5$ kcal. Tschiukow-Roux (15) has investigated the same reaction in a shock tube, but was unable to obtain sufficient variation of rate with pressure to calculate the high pressure limit.

* Points ommitted due to failure of a statistical test ** Calculated from the 3rd law heat of reaction.

A median value of $\Delta_f H(CF_2, g, 298.15\ K)$ covering the area of maximum probability is adopted as $-43.5 \pm 1.5\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The structure of CF_2 has been reported by Powell and Lide (16) from microwave measurements and has been confirmed by Mathews (17) from the fine structure of the 2500Å absorption band. Mathews also reported ω_2, and Herr and Pimentel (18) reported ω_3, both from gas phase studies. Milligan et al. (19) have observed all three vibrations in matrix-isolated CF_2 as 1222, 668 and 1102 cm^{-1}. The electronic levels are from Mathews (17) with the triplet level estimated by Simons (20) to explain the low C=C bond energy of 70 kcal in C_2F_4.

Point Group: C_{2v}
Bond Distance: C-F = [1.32] Å
Bond Angle: F-C-F = [116 ± 10°]
Product of the Moments of inertia: $I_A I_B I_C = [5.07002 \times 10^{-116}]\ g^3\ cm^6$

Enthalpy of Formation

The ionization potential has been reported as 11.7 eV (1), 11.8 eV (2,3), and 11.86 eV (4) from electron impact measurements. Since there may be excess energy involved we prefer the lowest value, 11.7 ± 0.2 eV. This leads to $\Delta_f H°(CF^+, g, 0\ K) = 226.2 \pm 6\ kcal\ mol^{-1}$ using the JANAF $\Delta_f H°(CF_2, g, 0\ K) = -43.61 \pm 1.5\ kcal\ mol^{-1}$ (5).

A more precise value is available from the photoionization measurements of Walter et al. (6), who measured the photoionization threshold the process. for

$$C_2F_4 + h\nu \rightarrow CF_2^+ + CF_2 + e^- \qquad \Delta H°(0\ K) = 337.4 \pm 0.9\ kcal\ mol^{-1}$$

Employing JANAF auxiliary enthalpies (5) we obtain $\Delta_f H°(CF_2^+, g, 0\ K) = 223.5 \pm 3.0\ kcal\ mol^{-1}$ which is adopted.

Heat Capacity and Entropy

The configuration of CF_2^+ is predicted to be bent by Walsh (7), since it has 17 electrons, thus, its ground state is $^2A_1$, a low lying electronic state is predicted by analogy with NO_2 (8). We estimate the angle to be 116 ± 10°, which is larger than CF_2 at 105°, this is expected from the Walsh correlations (7), but smaller than isoelectronic CO_2^- at 127° and NO_2 at 134°. The vibrational frequencies were estimated by comparison with those for CF_2, CO_2^- and COF (7) as 1100 ± 150 cm^{-1}, 650 ± 50 cm^{-1} and 1400 ± 200 cm^{-1}.

The principal moments of interia are: $I_A = 0.7415 \times 10^{-39}$, $I_B = 7.9066 \times 10^{-39}$ and $I_C = 8.6481 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

Ruff and Li (1) measured equilibrium constants for the reaction

$$2COF_2(g) \rightleftharpoons CO_2(g) + CF_4(g)$$

in the temperature range 573-1273 K. These equilibrium data were recently analyzed by Stull, Westrum, and Sinke (2). Their 3rd law analysis of the data clearly indicates that the three low temperature points are in error and should not be used in calculating $\Delta_r H(298.15\ K)$. They reported $\Delta_r H(298.15\ K) = -12 \pm 3\ kcal\ mol^{-1}$ based upon an average of the five high temperature points. Combining this result with the enthalpy of formation of carbon dioxide and carbon tetrafluoride (3), we derive,

$$\Delta_f H°(COF_2,\ g,\ 298.15\ K) = -152.5 \pm 3.3\ kcal\ mol^{-1}.$$

Wartenberg and Riteris (4) measured the enthalpy of hydrolysis of CF_2O. They reported $\Delta_r H = -26.7 \pm 0.2\ kcal\ mol^{-1}$ for the reaction

$$COF_2(g) + H_2O(\ell) + CO_2(g) + 2HF \cdot 300\ H_2O.$$

Combining this result with enthaply of formation data for carbon dioxide and $HF(\Delta_f H°(HF \cdot 300\ H_2O,\ 298.15\ K) = -76.84\ kcal\ mol^{-1}$ (5)), we derive

$$\Delta_f H°(COF_2,\ g,\ 298.15\ K) = -152.7 \pm 0.4\ kcal\ mol^{-1}.$$

Armstrong, Coyle, and Krieger (6) measured the enthalpies of combustion of CH_4 in O_2-F_2 mixtures and found $\Delta_f H°(COF_2,\ g,\ 298.15\ K) = -154.8\ kcal\ mol^{-1}$. *The value calculated from* Wartenberg's data is adopted here.

Heat Capacity nd Entropy

The vibrational frequencies are from the infrared studies of Hopper et al. (7) and are in good agreement with the results of Lovell et al. (8) and Nielsen et al. (9). The molecular constants are from the microwave studies of Laurie et al. (10) and are in reasonable agreement with the electron-diffraction work of Brown and Livingston (11). The principal moments of inertia are: $I_A = 7.1086 \times 10^{-39}$, $I_B = 7.1359 \times 10^{-39}$, and $I_C = 14.2445 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: 2 $\sigma = 3$
Point Group: C_{3v}
Bond Distance: C-F = [1.33] Å
Bond Angle: F-C-F = [112]°
Product of the Moments of Inertia: $I_A I_B I_C = [9.610547 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the enthalpies of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Kinetic data provide the most consistent paths to $\Delta_f H°$ of $CF_3(g)$. Forward and reverse activation energies for the reactions $CHF_3(g) + X(g) \rightarrow CF_3(g) + HX(g)$ have been reported for X = Cl by Coomber (2), for X + Br by Amphlett (3), and for X = I by Goy (4). Increases of about 0.3 kcal mol^{-1} in the reverse activation energies for X = Cl and Br were proposed by Arthur (5) on the basis of additional data. Combining these values and reducing to 298.15 K, we get $\Delta_r H° = 2.93 \pm 0.7$ (X = Cl), 18.89 ± 0.7 (X = Br), and 35.5 ± 3 kcal mol^{-1} (X = I). Coomber (2) reviewed data for the analogous reactions with X = CH_3 and CD_3; these yield $\Delta_r H° = 0.6 \pm 2$ kcal mol^{-1} at 298.15 K for X = CH_3. Activation energies have also been reported (6) for $CF_3I(g) + I(g) \rightarrow CF_3I(g) + I_2(g)$ from which we derive the average value $\Delta_r H° = 17.1 \pm 2$ kcal mol^{-1}. The data of Tschuikow-Roux (7) for $C_2F_6(g) \rightarrow 2CF_3(g)$, recalculated as suggested by Coomber (8) but with JANAF functions, yield $\Delta_r H° = 97.6 \pm 6$ kcal mol^{-1}. Differences between the calculated and observed values of $\Delta_r H°$ are all less than half of the uncertainties assigned to the observed values.

The thorough discussion of photoionization data by Noutary (9) emphasized that CF_3^+ is formed with large amounts of excess energy both during ionization of CF_3 and during fragmentation of other fluorides. The amount of excess energy varies with the parent molecule. This may also be involved in electron-impact studies and could account for some of the discrepancies in bond-dissociation energies derived from appearance potentials and ionization potentials. Such data have been summarized by Coomber (10). Ionization data were omitted from the simultaneous adjustment due to uncertainty in the amounts of excess energy.

Also omitted was the mass-spectrometric study of $3C_2F_4(g) \rightarrow 4CF_3(g) + 2C(graphite)$ by Ehlert (11) which gave $\Delta_r H° = -102 \pm 3$ kcal mol^{-1}. The discrepancy of 10 kcal mol^{-1} suggests that the data may not represent equilibrium for the above reaction. This reaction was one of many which resulted from heating MnF_3 in an effusion cell made of graphite.

Heat Capacity and Entropy

The bond length is assumed to be 1.33 Å by comparison with the molecules CF_3X, and the bond angle is estimated from molecular-orbital calculations of Morokuma (12) and Pople and coworkers (13). The nonplanar structure is consistent with electron-spin-resonance spectra (14) of CF_3 in krypton and xenon matrices, with infrared spectra of CF_3 in various matrices (15) and in the gaseous phase (16), and with photoionization spectra (17). The principal moments of Inertia are: $I_A = I_B = 7.9146 \times 10^{-39}$ and $I_C = 15.3421 \times 10^{-39}\ g\ cm^2$. The observed vibrational fundamentals of Carlson (16) are confirmed by the matrix spectra of Milligan (15). The latter estimated ν_4 to be in the range of 500 to 600 cm^{-1}. We choose the lower value by comparison with CF_3H, SiF_3H and SiF_3 (18).

The uncertainty in ν_4 corresponds to an uncertainty in the entropy of 0.4 cal $K^{-1}\ mol^{-1}$ at 300 K and 0.7 cal $K^{-1}\ mol^{-1}$ at 1000 K. Coomber (2) and Amphlett (19) used kinetic data to derive entropies of 63.2 cal $K^{-1}\ mol^{-1}$ at 350 K and 71.5 cal $K^{-1}\ mol^{-1}$ at 600 K. The calculated entropies from this table are higher by 2.0 and 1.7 cal $K^{-1}\ mol^{-1}$, respectively. These differences are only slightly larger than our estimate of the uncertainty in the kinetic results. We estimate the overall uncertainty in the calculated entropies as 1.0 cal $K^{-1}\ mol^{-1}$ at 298.15 K and 1.6 cal $K^{-1}\ mol^{-1}$ at 1000 K.

Enthalpy of Formation

The ionization potential of CF_3 has been carefully measured by Lifshitz and Chupka (1). They used a photoionization technique on CF_3 radicals prepared by heating CF_3CH_2ONO. Because of the low ionization cross-section near the threshold it is very difficult to determine the value exactly. The authors conclude that it is improbable that the ionization potential differs from 9.25 eV by as much as 0.2 eV. They choose to accept a value of 9.25 ± 0.04 eV (213.3 ± 0.9 kcal) based on their interpretation of the regular structure near the threshold. In a later paper, Walter, Lifshitz, Chupka and Berkowitz (9) use photodissociative ionization of CF_3I, CF_3BR and CF_3Cl to obtain an indirect ionization potential for CF_3 of 9.11 eV. We adopt a median value of 9.17 ± 0.08 eV (211.5 ± 1.8 kcal), which with $\Delta_f H°(CF_3, g, 0\ K) = -111.7 \pm 1.0\ kcmol^{-1}$ (2) gives $\Delta_f H°(CF_3^+, g, 0\ K) = 99.8 \pm 2.8\ kcal\ mol^{-1}$.

The above value supercedes all earlier values for the ionization potential of CF_3 which generally were obtained by electron impact methods, which do not have the energy resolution available in the photoionization technique. For further details of the older values see references 3, 4, 5, 6 and 7.

Heat Capacity and Entropy

The correlation rules proposed by Walsh (8) for AB_3 molecules indicate that molecules with less than 25 valence electrons are planar in their ground states. Since BF_3 is isoelectronic with CF_3^+, we estimate the vibrational frequencies by transferring the valence force field constants from BF_3 to CF_3^+. This gives 888, 674, 1404 and 480 cm^{-1}; however, Lifshitz and Chupka (1) conclude that the 674 cm^{-1} frequency is in fact at 830 cm^{-1}. This value is obtained from the spacings in the fine structure of the photoionization curve near threshold. They believe that the out-of-plane motion is most likely to be excited by the transition from pyramidal CF_3 to planar CF_3^+, thus, they ascribe the 830 cm^{-1} spacing to this motion. We adopt this one frequency in place of the calculated value. The bond lengths are assumed equal to those in CF_3. The principal moments of inertia are: $I_A = I_B = 8.3708 \times 10^{-39}$, and $I_C = 16.7416 \times 10^{-39}\ g\ cm^2$.

Bond Angles: F-C-F = 108.3° ± 1° F-C-I = 110.62°
Product of the Moments of Inertia: $I_A I_B I_C = 4.410587 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the enthalpies of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Lord, Goy and Pritchard (2, 3) report equilibrium data for the reactions $CF_3X(g) + I_2(g) = CF_3I(g) + XI(g)$ where X = H, Cl, and Br. In addition to these prime links, there is a weak link to CF_3 through kinetic studies of $CF_3I(g) + I(g) \rightarrow CF_3(g) + I_2(g)$. Data for this reaction (3, 12) yield the average value $\Delta_r H° = 17.1 \pm 2$ kcal mol^{-1} at 298.15 K.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Bowen (4), Anderson (5), and Wong and Schomaker (6). Differences among the data are small. The results of Anderson are adopted since they are intermediate between the others. Microwave data (7) are consistent with the adopted parameters. Infrared spectra of the gas were observed by several investigators (8, 9, 10) and Raman spectra of the liquid were obtained by Edgell and May (10). The vibrational assignments of (9, 10) are in close agreement. These assignments are adopted but preference is given to frequencies observed for the gas. In particular, ν_6 is taken as 260 cm^{-1} (from overtone and combination bands of the gas) rather than 265 cm^{-1} (from the Raman spectra of the liquid). The approximate values of ν_2, ν_3 abd ν_6 have been confirmed by analysis (11) of absorption spectra in the UV.

The thermodynamic functions of this table are essentially the same as those calculated by (9). Uncertainty in the entropy is estimated to vary from 0.15 to 0.6 cal K^{-1} mol^{-1} over the range from 300 to 1000 K. Uncertainty in ν_6 and neglect of anharmonicity are the major sources of error. Discussions of the magnitude of anharmonic effects appear on the tables for $CClF_3(g)$ and $CF_4(g)$. The principal moments of inertia are: $I_A = 14.7097 \times 10^{-39}$ and $I_B = I_C = 54.7578 \times 10^{-39}$ g cm^2.

$S°(298.15\ K) = 261.419 \pm 0.25\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -927.23 \pm 1.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -933.20 \pm 1.3\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
908.5 (1)	1283.0 (3)
435.0 (2)	631.5 (3)

Ground State Quantum Weight: 1 $\sigma = 12$
Point Group: T_d
Bond Distance: C-F = 1.320 Å
Bond Angle: F-C-F = 109.4712°
Product of the Moments of Inertia: $I_A I_B I_C = 3.149690 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the enthaplies of formation of HF(g), HF(50 H_2O) and five closely related fluorides. Adjustment of 23 selected observations relating the 7 variables gives the following enthalpies of formation in kcal mol^{-1} at 298.15 K: HF(g), -65.14 ± 0.2; HF(50 H_2O), -76.78 ± 0.1; NaF(cr), -137.52 ± 0.2; BF_3(g), -271.42 ± 0.4; CF_4(g), -223.04 ± 0.3; NF_3(g), -31.43 ± 0.3; and C_2F_4(polymer), -198.2 ± 0.7. The ± values are estimates of the overall uncertainty including systematic error. Further details of the simultaneous adjustment are given in (1).

The selected value is essentially the same as that obtained by Greenberg and Hubbard (2) in their thorough calorimetric study of the combustion in fluorine of natural and synthetic graphite. Their results is confirmed by the data of Domalski and Armstrong (3) for combustion of graphite-Teflon mixtures. Reliable data (1) also link CF_4(g) with HF(n H_2O), NF_3(g) and C_2F_4(polymer). Armstrong (4, 3) critically reviewed the more uncertain data which were omitted from the adjustment.

Heat Capacity and Entropy

The fundamental vibrations are those observed in the gas-phase Raman spectra by Monostori and Weber (5) and the gas-phase infrared spectra by Maki et al. (6) and Chalmers and McKean (7). The frequencies are essentially the same as those selected by Shimanouchi (8) who also lists earlier spectral studies. Electron-diffraction studies of the gas were reported by Thornton (9) and Hoffman and Livingston (10). The adopted bond length is the average of these two results which differ by only 0.006 Å. The principal moments of inertia are: $I_A = I_B = I_C = 14.6585 \times 10^{-39}\ g\ cm^2$.

The most significant uncertainty in the calculated thermodynamic functions is due to neglect of anharmonic contributions. Estimates for these contributions were given by Barho (11) and Albright et al. (12), and functions calculated with anharmonic terms were given by McBride et al. (13). Differences between McBride and this JANAF table vary from 0.1 to 0.75 cal $K^{-1}\ mol^{-1}$ in Cp° and 0.05 to 0.49 cal $K^{-1}\ mol^{-1}$ in S° over the range from 300 to 1000 K. Measurements (14) of C_v(303-473 K) suggest that anharmonic contributions are significant, but the data are not sufficiently accurate to test the calculations of McBride (13). Heat capacity data (15) for the condensed phases were reviewed by Kelley and King (16) who derived S°(298.15 K) = 62.8 ± 0.5 cal $K^{-1}\ mol^{-1}$ for CF_4(g).

Ground State Quantum Weight: 1 $\sigma = 1$
Point Group: C_s
Bond Distances: C-F = [1.33] Å F-O = [1.42] Å C-O = [1.43] Å
Bond Angles: C-O-F = [103.2]° F-C-F = [109.5]°
Product of the Moments of Inertia: $I_A I_B I_C = 1.151629 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

Porter and Cady (1) measured equilibrium constants for the reaction $CF_3OF(g) = COF_2(g) + F_2(g)$ in the temperature range 630-750 K. Equilibrium constants were also determined with excess fluorine added to the system. 2nd and 3rd law analyses of these data yield the following enthalpy of reaction:

	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
Set 1	27.65 ± 0.2	30.10	3.6 ± 0.3
Set added fluorine	25.11 ± 0.3	30.09	7.2 ± 0.5

The 3rd law analyses indicate significant trends within each set of equilibrium data. If the entire error is assigned to the Gibbs energy functions, then the drifts in the 3rd law analysis imply that the Gibbs energy functions for CF_3OF should be increased by 3.6 or 7.2 cal K^{-1} mol^{-1}. However, the real error in these Gibbs energy functions is probably no larger than 1 cal K^{-1} mol^{-1} in the temperature range of the experimental data. Apparently, the equilibrium reaction investigated by Porter and Cady (1) was affected by side reactions possibly involving perfluorodimethyl peroxide. However, since the only other approach to the enthalpy of formation of CF_3OF involves bond energies, we adopt the 3rd law value, $\Delta_r H° = 30.1$ kcal mol^{-1}, and derive $\Delta_f H°(CF_3OF, g, 298.15\ K) = -182.8 \pm 3$ kcal mol^{-1} with $\Delta_f H°(COF_2, g, 298.15\ K) = -152.7 \pm 0.4$ kcal mol^{-1} (2).

Czarnowski et al. (3) recently determined the O-F bond energy in CF_3OF from kinetic studies on the thermal decomposition of CF_3OF in the presence of SO_3. They reported the value $D_0^0(O\text{-}F) = 43.5 \pm 0.5$ kcal mol^{-1}. Combining this result with the following data,

$\Delta_f H°(C, g, 298.15\ K) = 170.89 \pm$ kcal mol^{-1} (4)
$\Delta_f H°(F, g, 298.15\ K) = 18.86 \pm 0.40$ kcal mol^{-1} (5)
$\Delta_f H°(O, g, 298.15\ K) = 59.559 \pm 0.03$ kcal mol^{-1} (6)
$D_0^0(C\text{-}F) = 117.4$ kcal mol^{-1} (from $\Delta_f H°(CF_4, g, 298.15\ K) = -223.04 \pm 0.3$ kcal mol^{-1} (7)
$D_0^0(C\text{-}O) = 84$ kcal mol^{-1} (8)

we derive $\Delta_f H°(CF_3OF, g, 298.15\ K) = -173.8$ kcal mol^{-1}.

The value determined from Porter and Cady's equilibrium data is adopted here.

Heat Capacity and Entropy

The vibrational frequencies are from the intrared and Raman studies of Wilt and Jones (9) and are in reasonable agreement with nine of the twelve expected fundamentals observed by Lagemann et al. (10). Bond lengths and angles are estimated quantities chosen by Wilt and Jones (9). The principal moments of inertia are: $I_A = 14.8190 \times 10^{-39}$, $I_B = 27.8485 \times 10^{-39}$, and $I_C = 27.9057 \times 10^{-39}$ g cm^2. The contributions of hindered internal rotation to the thermodynamic properties of CF_3OF are from the tables of Pitzer and Gwinn (11). The reduced moment of inertia, I_r, and the potential barrier, V_o, are from the work of Wilt and Jones (9) and are:

$$I_r = 2.939 \times 10^{-39}\ g\ cm^{-1} \qquad V_o = 1130\ kcal\ mol^{-1}\ (\nu_{12} = 56\ cm^{-1})$$

Reduced Moment of Inertia: $I_{red} = [9.9216 \times 10^{-39}]\ g\ cm^2$

Enthalpy of Formation

We adopt $D°(CF_3-SF_5) = 80 \pm 10$ kcal mol^{-1} from which $\Delta_f H°$ is calculated to be -406.4 ± 15 kcal mol^{-1} at 0 K by combining D° with $\Delta_f H°(CF_3, g) = -111.7 \pm 1.0$ kcal mol^{-1} and $\Delta_f H°(SF_5, g, 0\ K) = -214.7 \pm 3.6$ kcal mol^{-1} (1). We estimate that the D°(C-S) in CF_3SF_5 of the C-C, S-S, and C-S bond lengths and the corresponding stretching frequencies for C_2F_6, S_2F_{10}, and CF_3SF_5 indicates that D°(C-S) should be intermediate between those for C-C and S-S. We calculate the heat of atomization ($\Delta_a H°$) and $\Delta_f H°$ value at 298.15 K as 788.6 ± 19 kcal mol^{-1} and -410.385 ± 15 kcal mol^{-1}, respectively.

Heat Capacity and Entropy

The microwave spectrum of CSF_8 observed by Kisliuk and Silvey (2) shows that the molecule is a symmetric rotor comprised of CF_3 and SF_5 groups joined by a C-S bond. The infrared (3, 4) and Raman (4) spectra obey the selection rules predicted for the point group C_{4v}. We estimate all structural data except for the C-S bond length by analogy with the CF_3 structure in C_2F_6 and the SF_5 structure in S_2F_{10} (1). We select a value for the C-S bond length which when combined with the estimated data reproduces the experimentally determined amount of inertia ($I_A = I_B = 7.656 \times 10^{-38}$ g cm^2, 2) within the experimental error. The principal moment of inertia about the symmetry axis is $I_C = 45.3692 \times 10^{-39}$ g cm^2.

The vibrational frequencies are rounded values taken from the gas phase infrared and liquid phase Raman study of Griffiths (4). The infrared data are supported by results obtained in an earlier study (3). Griffiths (4) assigned the Raman band at 262 cm^{-1} to the b_1 SF_2 out-of-plane deformation mode (ν_9) by analogy with his assignment for $ClSF_5$ (ν_6 = 271 cm^{-1}). More recent information (1) on $ClSF_5$ indicates that the 271 cm^{-1} Raman band is the low-frequency SF_5 rocking fundamental π_{11}. By analogy with this new assignment for $ClSF_5$, we assign the infrared band observed at 290 cm^{-1} by Griffiths (4) to the SF_5 rocking fundamental (π_{16}). The Raman band at 319 cm^{-1} is believed to be π_9 since it is close to the values (332 cm^{-1} and 317 cm^{-1}) predicted for the analogous deformation mode (π_6) in $ClSF_5$ (1) by force field calculations. We assume that the internal rotation about the C-S bond is unrestricted based on spectroscopic evidence (3, 4) which indicates that the barrier is very small. Kisliuk and Silvey (2) have derived a potential barrier of 219 cm^{-1} (0.63 kcal mol^{-1}) from satellite lines observed in their microwave spectrum; however, these lines are probably due to the CF_3 rocking mode (π_{17}) rather than the torsional vibration (π_7), as indicated by Eggers et al. (3). The overall symmetry number is calculated as the product of the external (λ) and internal ($\times$) symmetry numbers with $\times$ assumed equal to 12.

Enthalpy of Formation

Herzberg (1) reanalyzed the rotational predissociation reported by Shidei (2) and concluded that D^0_0 = 80.0 kcal mol^{-1} (3.47 eV). This yields $\Delta_f H°(CH, g, 298.15\ K)$ = 142.0 kcal mol^{-1}(594.128 ± 17.5 kJ mol^{-1}), and is the adopted value.

Brewer and Kester (3) have confirmed the value as 142 ± 5 kcal mol^{-1}, from an equilibrium study of the temperature variation of the intensity of the $^2\Delta \rightarrow {}^2\Pi$ emission band.

Linevsky (4) determined the concentration of CH radicals in equilibrium with 1 atm. of hydrogen gas, by application of a high resolution spectro-photographic technique to three electronic transitions in absorption. A third law analysis, using the present functions, of 27 determinations in the temperature range 3065 - 3155 K yielded $\Delta_f H°(CH, g, 298.15\ K)$ = 142.01 ± 1.28 kcal mol^{-1} with a negligible drift. This value is in excellent agreement with the spectroscopic predissociation value.

Heat Capacity and Entropy

The vibrational and rotational constants and electronic levels are from Herzberg (1) with the exception of the estimated $^4\Sigma$ level. All the constants have been adjusted to the normal isotopic abundances for both carbon and hydrogen. The $^4\Sigma$ level is estimated from the ab initio calculations of Hurley (5) which include electron correlation effects. Earlier LCAO calculations had predicted the $^4\Sigma^-$ level to be the ground state, but Higuchi (6) used LCAO-SCF calculations and obtained the $^4\Sigma$ level at 800 cm^{-1}. Krauss and Wehner (7), using essentially the same technique as Hurley (5), obtained $^4\Sigma$ at 3000 cm^{-1}.

PREVIOUS: December 1967 (1 atm) CURRENT: December 1967 (1 bar)

METHYLIDYNE, ION (CH^+) IDEAL GAS M_r = 13.01839

$S°(298.15\ K) = 171.67 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1623.40 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 1626.74 \pm 2.1\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1
$^1\Pi$	23596.94	2

$\omega_e = 2885.7\ cm^{-1}$ $\omega_e x_e = [73]\ cm^{-1}$ $\sigma = 1$

$B_e = 14.1776\ cm^{-1}$ $\alpha_e = 0.4917\ cm^{-1}$ $r_e = 1.3909$ Å

Enthalpy of Formation

Douglas and Herzberg (1) first observed the spectrum of CH^+ and concluded that $D_0^0(CH^+) = 3.61 \pm 0.22$ eV from a short extrapolation of the A state vibrational separations, this leads to IP = 11.13±0.22 eV. Later Douglas and Morton (2) showed that the basis for this extrapolation was incorrect and the value was thus invalidated. Herzberg and Johns (3) then reported a value of IP(CH) = 10.64 eV (245.36 kcal mol^{-1}) which was obtained from the limit of the Rydberg states of CH (see also Herzberg (4)). This value in conjuntion with the JANAF value for $\Delta_f H°(CH, g, 0\ K) = 141.178$ kcal mol^{-1} leads to $\Delta_f H°(CH^+, g, 0\ K) = 386.5 \pm 0.5$ kcal mol^{-1} (1617.116±2.1 kJ mol^{-1}) and is adopted.

Heat Capacity and Entropy

The molecular constants are those reported by Douglas and Morton (2). The value for ω_e is derived from the observed $\Delta G_{1/2}$ by adding $2\omega_e x_e$. The $\omega_e x_e$ value is that calculated by Moore et al. (5) from ab initio variational calculations of the $^1\Sigma$ and $^1\Pi$ states.

Ground State Quantum Weight: 1 σ = 1

Point Group: C_s

Bond Distances: C-H = 1.12 Å C-Cl = 1.689 Å

Bond Angle: H-C-Cl = 103.4°

Product of the Moments of Inertia: $I_A I_B I_C = 3.9883 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation can be estimated as the average of those of the CH_2 and CCl_2 radicals, which gives $\Delta_f H°$(CHCl, g 298.15 K) = 74.5 ± 15 kcal mol^{-1}. A better value for the enthalpy of formation can be obtained by considering the reactions CHCl → CH + Cl and CHCl → CCl + H. When $\Delta_f H°$(CCl, g, 298.15 K) = 74.5 kcal mol^{-1} is substituted into the above equations it gives D_0^0(C-Cl) = 96 kcal and D_0^0(C-H) = 98 kcal. Although these values are not unreasonable, the D_0^0(C-H) value appears to be too high compared to that in CFH. Thus, we adopt $\Delta_f H°$(CHCl, g, 298.15 K) = 80 kcal mol^{-1} which gives D_0^0(C-Cl) = 91 kcal and D_0^0(C-H) = 92 kcal.

Heat Capacity and Entropy

The structure and electronic levels of the molecule have been established by Merer and Travis (1) from an analysis of the rotational structure of the visible absoorption bands. The estimated triplet state is based on the electronic levels of CCl_2 and CH_2 as given in these tables. The vibrational levels are from Jacox and Milligan (2) who investigated the infrared spectrum of matrix-isolated CHCl, and also estimated the missing frequency.

The principal moments of inertia are: $I_A = 0.1780 \times 10^{-39}$, $I_B = 4.6457 \times 10^{-39}$, and $I_C = 4.8237 \times 10^{-39}\ g\ cm^2$.

Bond Angles: H-C-Cl = 107° Cl-C-F = 110.5° F-C-F = 107°
Product of the Moments of Inertia: $I_A I_B I_C = 3.435053 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

Edwards and Small (1) determined a single equilibrium constant at 600°C for the reaction $2CHClF_2(g) \rightarrow C_2F_4(g) + 2HCl(g)$. The value was not obtained directly but was obtained by extrapolation to eliminate the effects of side reactions. The equilibrium constant was used with JANAF free energy functions (2) to obtain $\Delta_r H°(298.15\ K) = 28.75$ kcal, which yields $\Delta_f H°(CHClF_2, g, 298.15\ K) = -115.1\ kcal\ mol^{-1}$. An uncertainty of ±3 kcal mol^{-1} corresponds to an uncertainty of about ±500% in the equilibrium constant.

Heat Capacity and Entropy

The gas phase vibrational frequencies have been observed in the Raman by Holzer and Moser (3); they do not see anything in the 1350 cm^{-1} region as reported in the liquid by Glockler and Edgell (4). Plyler and Benedict (5) in their assignment replaced an 831 cm^{-1} frequency by 1178 cm^{-1}. We essentially adopt Glockler and Edgell's assignment with updated gas phase values for the observed frequencies. The microwave spectrum has been analyzed by McLay and Mann (6) and Beeson et al. (7), who derive bond lengths and angles in excellent agreement with each other. The values given by Beeson et al. are adopted here.

Neilson and White (8) have measured the low temperature heat capacity and heat of vaporization and have reported an entropy in the gas phase at 232.5 K of 63.919±0.28 cal $K^{-1}\ mol^{-1}$. This compares with 63.959 cal $K^{-1}\ mol^{-1}$ calculated from our adopted functions.

The principal moments of inertia are: $I_A = 8.2033 \times 10^{-39}$, $I_B = 17.4031 \times 10^{-39}$ and $I_C = 24.0612 \times 10^{-39}\ g\ cm^2$.

1313(1)	455 (1)	806(1)
1079(1)	270 (1)	368(1)

Ground State Quantum Weight: 1 σ = 1

Point Group: C_s

Bond Distances: C-H = 1.09 Å C-Cl = 1.75 Å C-F = 1.367 Å

Bond Angles: Cl-C-Cl = 112°12' F-C-Cl = 109° H-C-Cl = 109°45'

Product of the Moments of Inertia: $I_A I_B I_C = 1.110094 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

The change in enthalpy of atomization by successive replacement of F by Cl in the CF_4 to CCl_4 series follows a regular pattern (see CCl_2F_2 table). A similar pattern is to be expected in the CHF_3 to $CHCl_3$ series. The first replacement of the series is, in fact, 4 kcal higher than the mean versus 3.8 kcal higher in the CF_4-CCl_4 series. Thus, we have selected the atomization energy of the second and third replacements to continue this pattern. In this manner we have selected the atomization energy of $CHCl_2F$ as 367.4 kcal which corresponds to $\Delta_f H°(CHCl_2F, g, 298.15\ K) = -67.7\ kcal\ mol^{-1}$. With this adopted value, the successive replacement of F by Cl changes the enthalpy of atomization by 41.4, 37.3 and 33.0 kcal.

Heat Capacity and Entropy

Holzer (1) has reported the gas phase Raman spectrum which is in excellent agreement with the assignments of Plyler and Benedict (2). The only discrepancy is in ν_7, which Plyler and Benedict assign at 1242 cm^{-1}, and Holzer (1) does not report a band in this region. Holzer does, however, report a band at 728 cm^{-1} which has not been reported in the earlier liquid studies. There is strong evidence from correlations with $CHCl_3$ and CHF_3 that two frequencies should occur between 1220 and 1376 cm^{-1}. On this basis we adopt the assignment of Plyler and Benedict for ν_7, while accepting the gas phase values of Holzer for the other frequencies. The extra band at 728 cm^{-1} is not used. It is probable that the bands at 741 and 728 cm^{-1} are due to Fermi resonance of ν_4 with $2\nu_9$; the unperturbed level would lie at 735 cm^{-1}. The symmetry classes of ν_4 and $2\nu_9$ are identical and thus Fermi resonance is allowed.

McLay (3) has reported the molecular structure from his microwave investigations. The principal moments of inertia are: $I_A = 12.0028 \times 10^{-39}$, $I_B = 25.7010 \times 10^{-39}$ and $I_C = 35.9855 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

Hu and Sinke (1) have measured the enthalpy of combustion of $CHCl_3(\ell)$ in the rotating bomb calorimeter, using As_2O_3 solution as the reducing agent. The reported $\Delta_c H°(298.15\ K) = -113.10\ kcal\ mol^{-1}$ for $CHCl_3(\ell) + 0.50_2 + H_2O(\ell) + CO_2(g) + 3HCl(aq, 600H_2O)$ which leads to $\Delta_f H°(CHCl_3, \ell, 298.15\ K) = -32.10\ kcal\ mol^{-1}$, using $\Delta_f H°(298.15\ K) = -94.051, -39.823, -68.315\ kcal\ mol^{-1}$ for $CO_2(g)$, $HCl(aq, 600H_2O)$ and $H_2O(\ell)$, respectively (2). The standard deviation of six combustion runs was 0.09 kcal mol^{-1}. Employing the heat of vaporization of chloroform at 298.15 K as 7.44 kcal mol^{-1} (3), we obtain $\Delta_f H°(CHCl_3, g, 298.15\ K) = -24.66\ kcal\ mol^{-1}$ ($-103.177 \pm 1.3\ kJ\ mol^{-1}$) which is adopted in the tabulation.

Smith et al. (4), based on the combustion data of Eftring (5), re-evaluated the enthalpy of combustion of chloroform at 18.7°C as $\Delta_c E/M° = -947.7\ cal\ K^{-1}\ mol^{-1}$ for $CHCl_3(\ell) + 0.50_2(g) + H_2O(\ell) + CO_2(g) + 3HCl(aq, 600H_2O)$. This value needs to be further corrected for a change in the enthalpy of oxidation of As_2O_3 (6) and calculated to 25°C to give $\Delta_c H°(298.15\ K) = -113.44\ kcal\ mol^{-1}$, $\Delta_f H°(CHCl_3, \ell, 298.15\ K) = -31.76\ kcal\ mol^{-1}$ and $\Delta_f H°(CHCl_3, g, 298.15\ K) = -24.32\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (7), based on infrared and Raman spectra measured by Nielson and Ward (8), Madigan and Cleveland (9), Gibian and McKinney (10), and Stanevich and Yaroslaviskii (11).

The bond distances and angles were obtained from the microwave spectra by Jen and Lide (12). The principal moments of inertia are: $I_A = I_B = 25.7217 \times 10^{-39}$ and $I_C = 49.6081 \times 10^{-39}\ g\ cm^2$.

Product of the Moments of Inertia: $I_A I_B I_C = 1.0217 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation can be estimated as the average of those of the CH_2 and CF_2 radicals, which gives $\Delta_f H°(CHF, g, 298.15\ K) = 25 \pm 20\ kcal\ mol^{-1}$. A better value for the enthalpy of formation can be obtained by considering the bond energies CHF → CH + F and CHF → CF + H. When $\Delta_f H°(CHF, g, 298.15\ K) = 25\ kcal\ mol^{-1}$ is substituted into the above equations it gives $D_0{}^0(CF) = 136\ kcal\ mol^{-1}$ and $D_0{}^0(CH) = 86\ kcal\ mol^{-1}$. These are not unreasonable values but are probably close to the upper and lower limits respectively. A value of $\Delta_f H°(CHF, g, 298.15\ K) = 30\ kcal\ mol^{-1}$ gives $D_0{}^0(CF) = 131\ kcal\ mol^{-1}$ and $D_0{}^0(CH) = 81\ kcal$ which are more probable since both fall within the bounds of normal bond strengths. The strongest established C-F bond is 135 kcal in CF_3 and the weakest established C-H bond is 80 kcal in CH. We adopt $\Delta_f H°(CHF, g, 298.15\ K) = 30 \pm 7\ kcal\ mol^{-1}$ ($125.520\ kJ\ mol^{-1}$).

Heat Capacity and Entropy

The structure and electronic levels of the molecule have been established by Merer and Travis (1) from an analysis of the rotational structure of the visible absorption bands. The estimated triplet state is based on the electronic levels of CF_2 and CH_2 as given in these tables. The vibrational levels are from Merer and Trvis (1) and Jacox and Milligan (2), the latter investigated the infrared spectrum of matrix-isolated HCF and also estimated the missing frequency.

The principal moments of inertia are: $I_A = 0.1795 \times 10^{-39}$, $I_B = 2.2980 \times 10^{-39}$, and $I_C = 2.4774 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: C_1

Bond Distances: C-F = 1.31 ± 0.02 Å C-O = 1.183 ± 0.003 Å C-H = 1.10 ± 0.02 Å

Bond Angles: F-C-O = 122.7 ± 0.05° H-C-F = 108.3 ± 3° H-C-O = 129 ± 3°

Product of the Moments of Inertia: $I_A I_B I_C = 4.96336 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_r H°$ for III was estimated to be the average of the $\Delta_r H$'s of I and II.

(I) $CH_2O(g) = CO(g) + 2\ H(g)$ 106 kcal
(II) $CF_2O(g) = CO(g) + 2\ F(g)$ 162 kcal
(III) $CHFO(g) = CO(g) + F(g) + H(g)$ [134] kcal

The auxiliary $\Delta_f H°(298.15\ K)$ of CH_2O = -28, H = 52, F = 19, CO = -26, CF_2O = -150 kcal mol^{-1} was used. See the respective sheets for details. The estimated enthalpy of formation is consistent with the instability of CHFO(g) at room temperature.

Heat Capacities and Entropies

The molecular structural parameters were obtained by LeBlanc et al (1) from combining the results of microwave measurements with those of electron diffraction determined by Jones et al. (2). Agreement within the assigned uncertainties was obtained by Stratton and Nielsen (3) on the basis of infrared measurements.

Five of the fundamentals were observed by Stratton and Nielsen (3) in agreement with those obtained by Morgan et al. (4). The estimated frequency was based upon the observed value of 857.4 cm^{-1} for the fundamental in the infrared spectrum of the deuterated compound and the application of the Teller-Redlich isotope rule. The principal moments of inertia are: $I_A = 0.9081 \times 10^{-39}$, $I_B = 6.9527 \times 10^{-39}$, and $I_C = 7.8608 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the enthalpies of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Trifluoromethane is linked to HF(aq, 21.5 H_2O) by calorimetric data, to $CBrF_3(g)$ and $CF_3I(g)$ by equilibrium data, and to $CF_3(g)$ by kinetic data. Neugebauer (2) reported calorimetric data for $CHF_3(g) + 0.5\ O_2(g) + H_2O(\ell) = CO_2(g) + 3\ HF(aq, 21.5\ H_2O)$, where CF_4 was also formed in a competing reaction. Recalculation of the original data with $\Delta_f H°(CF_4, g, 298.15\ K) = -223.0\ kcal\ mol^{-1}$ yields the mean value of $\Delta_r H°(298.15\ K) = -90.35 \pm 0.7\ kcal\ mol^{-1}$, but the individual values of $\Delta_r H°$ show a disturbing trend with the amount of competing reaction. Possible causes for the trend include corrosion and error in the analysis of the reaction products. Calibration was done in the presence of HF in an attempt to eliminate the heat due to corrosion. Because of this unexplained trend, we increase the uncertainty to ±1.0 kcal mol^{-1}. Goy (3) and Coomber (4) determined equilibrium data for $CHF_3(g) + X_2(g) = CF_3X(g) + HX(g)$ where X = I and Br. Kinetic data pertinent to CHF_3 are noted on the table for $CF_3(g)$.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Thornton (5) and from microwave data by Ghosh (6). The results are in close agreement and average values are adopted. Vibrational frequencies are from the assignment of Long (7) who reviewed the spectral data and gave force-constant calculations. Preferences has been given to the gas-phase spectra, particularly the Raman data of Claassen (8). Shimanouchi (9) assigned ν_2 = 1117 rather than 1137 cm^{-1}, but he apparently did not consider the gas-phase data of (8, 10). The principal moments of inertia are: $I_A = I_B = 8.1086 \times 10^{-39}$ and $I_C = 14.7875 \times 10^{-39}\ g\ cm^2$.

Valentine (1)] used low-temperature calorimetric data to derive the ideal gas entropy at the normal boiling point of 190.97 K. The experimental value of 57.18 cal K^{-1} mol^{-1} is in good agreement with 57.216 cal K^{-1} mol^{-1} obtained from this table. Schwing (12) measured $C_v°$ for CHF_3 vapor (25-100°C) and confirmed that the vibrational assignment is adequate. Uncertainty in $C_p°$ and S° increases at higher temperatures due to neglect of anharmonicity in the calculations. Discussions of anharmonic contributions are given on the tables for $CF_4(g)$ and $CClF_3(g)$. The error probably does not exceed 0.3 cal K^{-1} mol^{-1} in S° at 1000 K. $C_p°$ is consistent with $C_v°$ measured at 300 K by the wire-ribbon method (13).

Spectroscopic constants used in calculating corrections to the rigid-rotator harmonic oscillator approximation (cm^{-1}):

$\alpha_1 = 10.10 \times 10^{-3}$ $-x_{11} = 7.07$ $-x_{12} = 2.53$ $g_{22} = 5.16$
$\alpha_2 = -3.61 \times 10^{-3}$ $-x_{22} = 2.65$ $-x_{23} = 19.01$
$\alpha_3 = 10.42 \times 10^{-3}$ $-x_{33} = 52.49$ $-x_{13} = 10.44$

Enthalpy of Formation

The value adopted is from NBS (1). The data of Thomsen (2) who measured both C_2N_2 and HCN and Berthelot (3) were used in conjunction with the well established value for C_2N_2 to derive the adopted value (4).

Badger (5) studied the equilibrium $NH_3(g) + C(cr) = HCN(g) + H_2(g)$ from both sides; we obtain a 3rd law $\Delta_r H°(298.15\ K)$ = 46±0.9 kcal and a 2nd law $\Delta_r H°(298.15\ K)$ = 34.5±19 kcal, the 3rd law drift is 14±24 cal $K^{-1}\ mol^{-1}$. The 3rd law value leads to $\Delta_f H°(HCN, g, 298.15\ K)$ = 35±1 kcal mol^{-1}.

Horiuchi et al. (6) studied the equilibrium $2\ CO(g) + NH_3(g) = HCN(g) + CO_2(g) + H_2(g)$. We obtain $\Delta_r H°(298.15\ K)$ = 1.1±0.5 kcal from a 3rd law analysis with a drift of -2±3 cal $K^{-1}\ mol^{-1}$, and a 2nd law value of 2.9±2.6 kcal. The 3rd law value leads to $\Delta_f H°(HCN, g, 298.15\ K)$ = 31.35±0.6 kcal mol^{-1}. The two sets of equilibrium data are self-consistent but disagree with each other and the direct combustions. We adopt an uncertainty of 2.0 kcal mol^{-1} to draw attention to this unsatisfactory situation.

Heat Capacity and Entropy

McBride et al. (7) used the constants listed above to calculate the adopted table which includes first and second corrections for anharmonicity, vibration-rotation interaction and centrifugal stretching. The bond lengths and molecular constants are those listed by Rank et al. (8). A more extensive set of anharmonic constants has recently been determined by Nakagawa and Morino (9), they are in generally good agreement with the values used.

PREVIOUS: December 1969 (1 atm) CURRENT: December 1969 (1 bar)

$S°(298.15\ K) = 238.228 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -98.7 \pm 8\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -101.7 \pm 8\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
3531(1)	659.8(1)
2274(1)	577.5(1)
1327(1)	777.1(1)

Ground State Quantum Weight: 1 $\sigma = 1$
Point Group: C_s
Bond Distances: H-N = 0.987 Å N-C = 1.207 Å C-O = 1.171 Å
Bong Angles: H-N-C = 128.1° N-C-O = 180°
Product of the Moments of Inertia: $I_A I_B I_C = 5.3166 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

Okabe (1) has measured the onset of photodissociation for the process HNCO(g) → NH(c' Π) + CO(g) as 8.79±0.03 eV (202.7±0.7 kcal). Okabe and Lenzi (2) have also reported the onset of photodissociation for the process NH_3(g) → NH(c'Π) + H_2(g) as 9.35±0.06 eV (215.6±1.4 kcal). Elimination of the NH(c'Π) gives

$$NH_3(g) + CO(g) \rightarrow NHCO(g) + H_2(g) \qquad \Delta_f H°(0\ K) = 12.9 \pm 2\ kcal$$

which with JANAF auxiliary data (3) yields $\Delta_f H°$(HNCO, g, 0 K) = -23.6±2 kcal mol^{-1}, or $\Delta_f H°$(HNCO, g, 298.15 K) = -24.3±2 kcal mol^{-1}.

The heat of formation of ionized cyanic acid in aqueous solution is -34.9 kcal mol^{-1} (4). Since the ions from cyanic acid and isocyanic acid are identical in solution we can use this value for aqueous isocyanic acid. Assuming the heat of solution is -3±3 kcal mol^{-1}, a value covering the range of heats of solution of most organic liquids (4), we obtain $\Delta_f H°$(HNCO, ℓ, 298.15 K) = -32±3 kcal mol^{-1}. Using $\Delta_{vap} H°$ = 7.2 kcal mol^{-1} (5) we obtain $\Delta_f H°$(HNCO, g, 298.15 K) = -25±3 kcal mol^{-1}. If we assume that $\Delta_f H°$(HNCO, g, 298.15 K) - $\Delta_f H°$(HNCO, ionized aq, 298.15 K) = $\Delta_f H°$(HNCS, g, 298.15 K) - $\Delta_f H°$(HCNS, ionized aq, 298.15 K) then we obtain $\Delta_f H°$(HNCO, g, 298.15 K) = -23 kcal mol^{-1} employing values from (4). We adopt the value $\Delta_f H°$(HNCO, g, 298.15 K) = -24.3±2 kcal mol^{-1} (-101.671±8 kJ mol^{-1}).

Heat Capacity and Entropy

The vibrational frequency determinations have been summarized by Herzberg and Reid (6). Ashby and Werner (7) have remeasured the three lower fundamentals under much higher resolution. They reverse the assignments of ν_5 and ν_6 of Herzberg and Reid. Dixon and Kirby (8) have discussed the corrections due to Coriolis interaction made by Ashby and Werner and conclude they are in the wrong direction. On this basis they reverse the ν_4 and ν_6 assignments of Herzberg and Reid.

The bond distances and angles are from the microwave measurements of Jones et al. (9) which give rotational constants in good agreement with the later microwave work of Kewley (10). The principal moments are: $I_A = 0.0912 \times 10^{-39}$, $I_B = 7.5910 \times 10^{-39}$, and $I_C = 7.6822 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

The adopted $\Delta_f H°$(HCO, g, 298.15 K) = 10.4±2 kcal mol^{-1} is calculated from $\Delta_{at}H°$(OHC-CHO, g) = 71.5±2 kcal mol^{-1} and $\Delta_f H°$(glyoxal, g, 298.15 K) = -50.66±0.2 kcal mol^{-1}. The C-C bond dissociation energy in glyoxal was determined from chemiluminescent recombination of formyl radicals by Hartley (1). The heat of formation of glyoxal was determined from flame combustion calorimetry by Fletcher and Pilcher (2).

The other route to derive the enthalpy of formation of formyl radical was from $\Delta_{at}H°$(H-CHO) which has been studied by many investigators listed below. There are several conflicting values between 77 to 91 kcal for $\Delta_{at}H°$(H-CHO). Based on the adopted $\Delta_f H°$(HCO, g, 298.15 K) = 10.4±2 kcal mol^{-1}, we have derived $\Delta_{at}H°$(H-CHO) = 89.3±2 kcal mol^{-1} which is in essential agreement with the high values of $\Delta_{at}H°$(H-CHO). The low values were probably not reliable as pointed out by Calvert (3), Walsh and Benson (5), Haney and Franklin (9).

Source	Method	$\Delta_{at}H°$(H-CHO) kcal mol^{-1}

Klein and Schoen (4)	Kinetic	77
Walsh and Benson (5)	Kinetic	87 ± 1
Brand and Reed (6)	Spectroscopic	<82.3
Reed and Brand (7)	Electron Impact	75 ± 2.3
Shannon and Harrison (8)	Electron Impact	79 ± 3
Haney and Franklin (9)	Electron Impact	87 ± 3

Heat Capacity and Entropy

The thermodynamic functions were calculated by summing over the individual partition functions for the separate states. The observed molecular constants and electronic levels were taken from Herzberg and Ramsay (10, 11, 12) and Dixon (13). The vibrational frequency (ν_1 = 2488 cm^{-1}) was observed using the matrix isolation infrared technique by Milligan and Jacox (14). Using the same technique, Ewing, Thompson and Pimentel (15) found ν_2 = 1091 cm^{-1} and ν_3 = 1860 cm^{-1} which are in good agreement with the values adopted (10). These small differences are probably due to matrix shifts. The bond lengths and angle were calculated from the normal coordinate analyses by Shirk and Pimentel (16). These values are a better fit than those calculated by Johns, Priddle and Ramsay (12) who assumed a normal CH bond length of 1.08 Å.

Enthalpy of Formation

Using the photoionization technique, Matthews and Warneck (1) measured the appearance potentials of HCO^+(g) from formaldehyde, formic acid and acetaldehyde as 11.95, 12.79 and 11.79 eV, respectively, whose average yields $\Delta_f H°(CHCO^+, g, 0\ K)$ = 197.7±1.5 kcal mol^{-1}, based on the following $\Delta_f H°(0\ K)$ data (in units of kcal mol^{-1}): 51.63 for H(g), 9.35 for OH(g), 35.62 for CH_3(g), -26.78 for H_2CO(g) (2), -88.74 for HCOOH(g) (3) and -37.14 for CH_3CHO (4). The appearance potentials obtained from photoionization are several tenths to 1 eV lower than the recent electron impact data (5, 6, 7, 8, 9). The appearance potentials determined by the electron impact method tend to be high because the fundamental nature of the process does not lead to a sharp onset in contrast to the step-function behavior of photoionization onset.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear based on two reasons: (1) the molecule HCO^+(g) is isoelectronic with HCN(g) which is linear; (2) A. D. Walsh (10) predicted that "HAB" molecules with 10 or less valence electrons will be linear in their ground state. HCO^+(g) has 10 valence electrons.

The bond distances HC and CO were estimated to be the same as those in HCN and HCO molecules, respectively. The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants which were obtained from HCN(g).

Spectroscopic constants used in calculating corrections to the rigid-rotator harmonic oscillator model (cm^{-1}):

$\alpha_1 = 3.4 \times 10^{-3}$ $\quad -x_{11} = [3.7]$ $\quad -x_{12} = [1.9]$
$\alpha_2 = -3.4 \times 10^{-4}$ $\quad -x_{22} = [2.4]$ $\quad -x_{23} = [18.0]$
$\alpha_3 = 3.1 \times 10^{-3}$ $\quad -x_{23} = [51.0]$ $\quad -x_{13} = [8.0]$

Point Group: $C_{\infty v}$ $\quad \sigma = 1$
Bond Distances: C-H = 1.0667 Å C-P = 1.5421 Å
Bond Angle: H-C-P = 180°
Rotational Constant: $B_0 = 0.667545\ cm^{-1}$

Enthalpy of Formation

The bonding in HCP and HCN is very similar, as evidenced by the bond lengths and vibrational frequencies. We assume that the C-H bond strength is thus the same in these two molecules. For the reactions HCN → H + CN we derive $\Delta_r H°$ = 123.8 kcal from $\Delta_f H°$(HCN, 298.15 K) = 32.3, $\Delta_f H°$(H, 298.15 K) = 52.1 and $\Delta_f H°$(CN, 298.15 K) = 104 kcal mol^{-1}. Applying this to the reaction HCP → H + CP, we obtain $\Delta_f H°$(HCP, g, 298.15 K) = 40±15 kcal mol^{-1}, from $\Delta_f H°$(CP, 298.15 K) = 111.7 kcal mol^{-1}.

Heat Capacity and Entropy

The molecular configuration was first reported by Gier (1), and later the bond lengths were determined by Tyler (2) using microwave spectroscopy. The vibrational frequencies and electronic levels were obtained from an analysis of the ultraviolet spectrum by Johns et al. (3). Since the first excited state is above 24000 cm^{-1} and the first nonlinear state at 34000 cm^{-1}, there is negligible error introduced by assuming ground state molecular constants for all excited states. The anharmonic constants were estimated from those of HCN by Gordon (4) and the adopted table includes these corrections and the electronic contributions.

Enthalpy of Formation

The electron impact data of Langer et al. (1) was reanalyzed by Prophet (2) to give $\Delta_f H°(CH_2, g, 298.15\ K)$ = 95±5 kcal mol^{-1}. Dibeler and Liston (3) reported the photoionization threshold for the process $CH_3CN + CH_2^+ + HCN$ as 14.94 eV (344.55 kcal mol^{-1}). *Using auxiliary data from (4) and (5)*, we obtain $\Delta_f H°(CH_2, g, 0\ K)$ = 95 kcal mol^{-1}, which is a maximum value as the process is likely to occur with excess energy. $\Delta_f H°(CH_2, g, 0\ K)$ values of 95.5 kcal mol^{-1} (a maximum) and 86.8±6.0 kcal mol^{-1} have been obtained by Chupka et al. from the appearance threshold of CH_2^+ from $C_2H_4(g)$ by photoionization (6), and from chemical equilibria measured in a mass spectrometer (7), respectively. Chupka (8) and Dibeler et al. (9) have determined the photoionization threshold for the production of CH_2^+ from CH_4. If the latter value is corrected for rotational energy effects as suggested by Chupka (8), then both studies yield $\Delta_f H°(CH_2, g, 0\ K)$ = 94.6 kcal mol^{-1}. Chupka (8) indicates that this is a maximum value since the process of H_2 elimation is likely to occur with excess energy in the products at the threshold.

Chupka and Lifshitz (10) have obtained the photoionization threshold for CH_2^+ from CH_3 as 15.09±0.03 eV. Combining this with the spectroscopic IP (4), they report $\Delta_{at}H°(CH_2\text{-}H)$ = 4.694±0.033 eV (108.25±0.77 kcal mol^{-1}). Using $\Delta_f H°(CH_3, g, 0\ K)$ = 35.64 kcal mol^{-1} and $\Delta_f H°(H, g, 0\ K)$ = 51.63 kcal mol^{-1} from these tables yields $\Delta_f H°(CH_2, g, 0\ K)$ = 92.24±1.0 kcal mol^{-1}.

Heat Capacity and Entropy

Bernheim et al. (11), in examining the EPR spectra of CH_2 which was produced by the photolysis of diazirine and trapped in xenon at 4 K, concluded that the ground state of CH_2 is a triplet state and it is bent. In similar followup work, they deduced a bond angle of 137.7±0.6 for CD_2 from a measurement of the isotropic component of the ^{13}C hyperfine interaction. Wasserman et al. (12), observing the EPR spectra on photolysis of diazomethane and diazirine at 4K, concluded that CH_2 has a triplet ground state with a probable bond angle of 136±8. Waserman et al. (13) also reported that their investigation of the EPR spectra of CD_2 and CHD supported their earlier conclusions (12). In these latter two works (12, 13), the bond angle was determined from the zero-field parameter. In more recent work by Wasserman et al. (14), the ^{13}C hyperfine structure was observed in the EPR spectrum of ground state $^{13}CD_2$ at 4 K. *The authors conclude* that ground state CH_2, by analogy, has an angle of 137-143°.

Herzberg and Johns (15) state that the electronic spectra of CH_2 and its isotopic derivatives is not only compatible with a linear ground state but it is also consistent with a bond angle of 136° if an ad hoc assumption of a heterogeneous predissociation of the excited state is made. Recent theoretical calculations indicate a bent ground state (16, 17). We adopt the triplet ground state, X $^3B_1$, as bent with an angle of 136±5° on the basis of the previously mentioned experimental work and weighted by the remarks of Herzberg and Johns (15). The bond length is 1.029 Å as reported by Herzberg (4). The bond lengths and angles for the a $^1A_1$ and b $^1B_1$ states are also from Herzberg and Johns (18).

The singlet electronic levels are firmly established (19). The unobserved singlet-triplet separation is likely to be less then 8000 cm^{-1}, as suggested by Herzberg (19). Many theoretical arguments yield energy separations within 10% of this value (16, 17, 20). *Goldberg and Riter (24) estimate* a value of 2600±2000 cm^{-1} by calculations which allow for correlation energy effects in different states, all assumed to be linear, however. Foner and Hudson (21) suggest a "small" separation due to the absence of resolved structure in the CH_2 ionization curve. Carr, Eder, and Topor (22) via ketone photolysis deduced an energy gap of roughly 350-700 cm^{-1}. Halberstadt and McNesby (23) suggest 880 cm^{-1} based on ketone photolysis in the presence of methane and propane. The value chosen for the singlet-triplet energy separation is 2600±2000 cm^{-1}. This value is intermediate between the experimental and theoretical suggestions.

The vibrational frequencies for the three lower lying states were calculated via the valence force field method using the force constants calculated by O'Neil, Schaeffer, and Bender (17). The geometry and vibrational levels for the c $^1A_1$ state were estimated. The uncertainty in the entropy mainly reflects the uncertain position of the low lying electronic levels.

Enthalpy of Formation

The change in enthalpy of atomization by successive replacement of F by Cl, in the CF_4 to CCl_4 series and CHF_3 to $CHCl_3$ series, follows a regular pattern (see CCl_2F_2 and $CHCl_2F$ tables). We make the assumption that this same regular variation occurs also in the CH_2F_2 to CH_2Cl_2 series. Thus, the difference between the atomization energies of CH_2F_2 and CH_2Cl_2 is divided into two unequal parts which fall into the pattern established in the CF_4 and CHF_3 sequences. We adopt an enthalpy of atomization of 385.5 kcal which corresponds to a $\Delta_f H°(CH_2ClF, g, 298.15\ K) = -62.6$ kcal mol^{-1}. The changes in kcal, in the enthalpy of atomization by successive replacement of F by Cl are tabulated, below for all three series.

CF_4		
43.8		
CF_3Cl	CHF_3	
41.6	41.4	
CF_2Cl_2	CHF_2Cl	CH_2F_2

$CFCl_3$	$CHFCl_2$	CH_2FCl
36.0	33.0	29.7
CCl_4	$CHCl_3$	CH_2Cl_2

Heat Capacity and Entropy

Plyler and Benedict (1) assigned the vibrational frequencies from the infrared and Raman data for the liquid. The molecular structure was obtained from the microwave measurements of Muller (2). The principal moments of inertia are: $I_A = 2.0097 \times 10^{-39}$, $I_B = 14.7640 \times 10^{-39}$, and $I_C = 16.2396 \times 10^{-39}$ g cm^2.

1467 (1)	1153 (1)	1268 (1)
717 (1)	3040 (1)	758 (1)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distances: C-H = 1.068 Å C-Cl = 1.7724 Å

Bond Angles: H-C-H = 112° Cl-C-Cl = 111.8°

Product of the Moments of Inertia: $I_A I_B I_C = 1.869359 \times 10^{114}\ g^3\ cm^6$

10-114

Enthalpy of Formation

Hu and Sinke (1) have measured the enthalpy of combustion of $CH_2Cl_2(l)$ in the rotating bomb calorimeter, using As_2O_3 solution as the reducing agent. They reported $\Delta_c H°(298.15\ K) = -144.00\ kcal\ mol^{-1}$ for $CH_2Cl_2(l) + O_2(g) + CO_2(g) + 2\ HCl(aq, 600\ H_2O)$ which leads to $\Delta_f H°(CH_2Cl_2, l, 298.15\ K) = -29.70\ kcal\ mol^{-1}$, using $\Delta_f H°(298.15\ K) = -94.051$ and $-39.823\ kcal\ mol^{-1}$ for $CO_2(g)$ and $HCl(aq, 600\ H_2O)$, respectively (2). The standard deviation of five combustion runs was 0.12 $kcal\ mol^{-1}$. Employing the heat of vaporization of $CH_2Cl_2(l)$ at 298.15 K as 6.87 $kcal\ mol^{-1}$ (3), we obtain $\Delta_f H°(CH_2Cl_2, g, 298.15\ K) = -22.83\ kcal\ mol^{-1}$ ($-95.521 \pm 1.3\ kJ\ mol^{-1}$) which is adopted in the tabulation.

L. Smith et al. (4), based on the combustion data of E. Eftring (5), re-evaluated the enthalpy of combustion of dichloromethane at 18.7°C as $\Delta_c E°/M = -1701.4\ cal/g$ for $CH_2Cl_2(l) + O_2(g) + CO_2(g) + 2\ HCl(aq, 600\ H_2O)$. This value needs to be further corrected for a change in the enthalpy of oxidation of As_2O_3 (6) and calculated to 25°C to give $\Delta_c E°(298.15\ K) = \Delta_c H°(298.15\ K) = -144.89\ kcal\ mol^{-1}$, $\Delta_f H°(CH_2Cl_2, l, 298.15\ K) = -28.80\ kcal\ mol^{-1}$ and $\Delta_f H°(CH_2Cl_2, g, 298.15\ K) = -21.93\ kcal\ mol^{-1}$.

J. Lacher et al. (7) have measured the enthalpy of hydrogenation of dichloromethane to methane and hydrogen chloride at 250°C as $-40.07\ kcal\ mol^{-1}$. Correction to 298.15 K gives $\Delta_f H°(CH_2Cl_2, g\ 298.15\ K) = -23.05\ kcal\ mol^{-1}$ which is in good agreement with the value adopted.

Heat Capacity and Entropy

The bond distances and angles have been determined from the microwave spectra by Meyers and Gwinn (8). The principal moments of inertia are: $I_A = 2.6307 \times 10^{-39}$, $I_B = 25.6246 \times 10^{-39}$ and $I_C = 27.7305 \times 10^{-39}\ g\ cm^2$.

The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (9), based on infrared and Raman spectra by Shimanouchi and Syzuki (10), Welsh et al. (11), and Palma et al. (12).

Bond Angles: F-C-F = 108° 17' ± 6' H-C-H = 111° 52' ± 25'

Product of the Moments of Inertia: $I_A I_B I_C = 1.22816 \times 10^{-115}\ g^3\ cm^6$

Enthalpy of Formation

Neugebauer and Margrave (1) measured the enthalpy of combustion of CH_2F_2. Their result for the combustion reaction

$$CH_2F_2(g) + O_2(g) + CO_2(g) + 2HF \cdot 21.5\ H_2O$$

was $\Delta_f H(298.15\ K) = -139.84 \pm 0.22$ kcal mol^{-1}. Using $\Delta_f H°(HF \cdot 21.5\ H_2O, 298.15\ K) = -76.75 \pm 0.1$ kcal mol^{-1} (2), obtained with dilution data compiled by Parker (3), we derive, $\Delta_f H°(CH_2F_2, g, 298.15\ K) = -107.7 \pm 0.4$ kcal mol^{-1} (-450.659 ± 1.7 kJ mol^{-1}) from Margrave's data.

Heat Capacity and Entropy

The vibrational frequencies are average values from the infrared studies of Stewart and Nielsen (4) and Plyler and Benedict (5). Principal moments of inertia are calculated from the rotational constants reported by Lide (6) with the result $I_A = 1.7088 \times 10^{-39}$, $I_B = 7.9171 \times 10^{-39}$, and $I_C = 9.0781 \times 10^{-39}\ g\ cm^2$. The molecular structure data are from the microwave studies of Lide (6) and are in excellent agreement with electron-diffraction studies of Brockway, Thornton, and Bartell whose results are reported in the Annual Review of Physical Chemistry (7).

Product of the Moments of Inertia: $I_A I_B I_C = 1.6597 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

Delepine and Badoche (1) measured the enthalpy of combustion of a formaldehyde polymer. Their value is revised to $\Delta_f H°(298.15\ K) = -25.0\ kcal\ mol^{-1}$ based on the following thermochemical cycle:

I	$C(cr) + 1/2O_2(g) + H_2(g) = \frac{1}{n}(CH_2O)_n(cr)$	-42.3 kcal
II	$[1/n]\ (CH_2O)_n(cr) + H_2O = CH_2O(aq)$	2.4
III	$CH_2O(g) = CH_2O(aq)$	14.9

Equation I and II are based upon data listed by Delepine and Badoche (1). For reaction III, Delepine and Badoche obtained 15 kcal mol^{-1}. Whereas, Walker (2) obtained 14.8 kcal mol^{-1}. A value of -27.7 kcal mol^{-1} is obtained from the combustion experiments of Wartenberg and Lerner-Steinberg (3). Corrections of -0.6 and 0.1 kcal mol^{-1} were applied to obtain a enthalpy of reaction at constant pressure and at 298.15 K.

Equilibrium constant determinations of reaction (IV) by Newton and Dodge (4) lead to a $\Delta_f H°(298.15\ K) = -29.0\ kcal\ mol^{-1}$.

IV $H_2(g) + CO(g) = H_2CO(g)$

The value obtained from the measurements of Wartenberg and Lerner-Steinberg (3) is believed to be the most reliable.

Heat Capacity and Entropy

Frequencies were measured by Blau and Nielson (5) in the I. R. Microwave determinations of Lawrence and Strandberg (6), and those of Erlandson (7) are in essential agreement. The principal moments of inertia are: $I_A = 0.3085 \times 10^{-39}$, $I_B = 2.1701 \times 10^{-39}$, and $I_C = 2.4786 \times 10^{-39}$ g cm^2.

Point Group: D_{3h} $\sigma = 6$
Bond Distance: C-H = 1.079 Å
Bond Angle: H-C-H = 120°
Product of the Moments of Inertia: $I_A I_B I_C = 4.99 \times 10^{-119}\ g^3\ cm^6$

Enthalpy of Formation

W. A. Chupka (1) measured the photoionization spectrum of methane and from the onset of CH_3^+ production has reported $\Delta_{at}H°(CH_3\text{-}H) = 103.244 \pm 0.12$ kcal. This value was corrected for the thermal rotation energy of the fragment ions and is the value adopted here.

V. H. Dibeler et al. (2) had earlier reported $\Delta_{at}H°(CH_3\text{-}H) = 101.7 \pm 0.5$ kcal but they did not apply the rotational energy correction, which would bring them closer to Chupka.

The photoionization values are in good agreement with earlier electron impact determinations as summarized by Stevenson (3) who gives $\Delta_{at}H°(CH_3\text{-}H) = 101.9 \pm 1$ kcal. Kinetic determinations have been recently reviewed by Kerr (4) and yield $\Delta_{at}H°(CH_3\text{-}H) = 102.5 \pm 1$ kcal again in excellent agreement.

Heat Capacity and Entropy

The structure, bond length, angles and electronic levels are those reported by Herzberg (5). A set of vibrational frequencies have been reported by Andrews and Pimentel (6) in an argon matrix, of which only two were observed. Milligan and Jacox (7) observed ν_2 = 611 cm^{-1} in an argon matrix and disagreed with Andrews and Pimentel who reported 730 cm^{-1}. Later Tan and Pimentel (8) agreed that the earlier values were for a methyl radical interacting with an alkali halide molecule. This would affect the ν_2 mode strongest, thus, we adopt the remaining in plane frequencies which appear to be of the correct magnitudes. The ν_2 mode is taken from the analysis of Herzberg (5) since this represents the gas phase molecule and is in reasonable agreement with the matrix value of Milligan and Jacox. The uncertainty in the entropy reflects the uncertainties in the vibrational frequencies.

The principal moments of inertia are: $I_A = I_B = 0.2923 \times 10^{-39}$, $I_C = 0.5846 \times 10^{-39}$ g cm^2.

Bond Angles: H-C-H = 108° H-C-Cl = 110°55'

Product of the Moments of Inertia: $I_A I_B I_C = 2.14799 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation has been determined by hydrogenation of methyl chloride to give methane and hydrogen chloride by Lacher, et al. (1), and by Lacher, et al. (2). They reported an average enthalpy of hydrogenation at 248°C to be -19,665±45 cal K^{-1} mol^{-1}. Using this value, together with JANAF data (5) for $H_2(g)$, $CH_4(g)$ and HCl(g), the enthalpy of formation of methyl chloride is calculated to be $\Delta_f H°(298.15\ K) = -20.69$ kcal mol^{-1}. Fowell, et al. [3], using a similar hydrogenation technique almost ten years later, report a value $\Delta_f H°(CH_3Cl, g, 298.15\ K) = -20.741$ kcal mol^{-1}.

Fletcher and Pilcher (4) derived the enthalpy of formation by measuring the enthalpy of combustion of methyl chloride by flame calorimetry. They reported a value $\Delta_f H°(CH_3Cl, g, 298.15\ K) = -19.59 \pm 0.16$ kcal mol^{-1} where the error, according to the authors, is twice the standard deviation of the mean including the uncertainty in calibration, measurement, determination of ignition energy, and values of auxiliary data used.

In support of their results, Fletcher and Pilcher (4) have compared the enthalpies of formation of $C_2H_5Cl(g)$ and i-$C_3H_7Cl(g)$ as determined by equilibrium studies (2nd and 3rd law) with their work via flame calorimetry. The agreement is excellent (<0.2 kcal mol^{-1} difference) but in both cases results for hydrogenation studies are at least 1 kcal mol^{-1} less negative. In the case of $CH_3Cl(g)$ no equilibrium results are currently available and the results of $\Delta_f H°(298.15\ K)$ from hydrogenation studies are approximately 1 kcal mol^{-1} more negative than the results from flame calorimetry.

The value chosen as the enthalpy of formation is $\Delta_f H°(CH_3Cl, g, 298.15\ K) = -20.0 \pm 0.5$ kcal mol^{-1}. This value is close to the median value and is arbitrarily chosen as it is uncertain whether the flame calorimetry or hydrogenation studies are the more accurate. Slightly more weight was given to the flame calorimetry work due to favorable comparisons with equilibrium studies in related compounds. An error of ± 0.5 kcal mol^{-1} is chosen so as to encompass the current $\Delta_f H°(298.15\ K)$ *experimental values even though the actual experimental error is considerably less.*

Heat Capacity and Entropy

The vibrational frequencies are essentially typical values which were taken from the experimental work of Plyler and Benedict (6), Reichman and Overend (7), Morino and Nakamura (8), Jones, et al. (9), Flether (10), and King, et al. (11). The value of ω_1 as given by Plyler and Benedict (6) appears too low and was not included. Costain (12) has calculated the bond distances and angles based on a isotopic substitution method. From this latter data, the moments of inertia are calculated to be: $I_A = 0.5263 \times 10^{-39}$ and $I_B = I_C = 6.3887 \times 10^{-39}\ g\ cm^2$.

Point Group: C_{3v}

Bond Distances: C-F = 1.391 ± 0.005 Å C-H = 1.095 ± 0.010 Å

Bond Angle: H-C-H = 109.5° ± 2°

Product of the Moments of Inertia: $I_A I_B I_C = 5.8630 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

Appearance potentials for CH_3^+ from CH_4 and CH_3F reported by Lossing, Ingold, and Henderson (1), the enthalpies of dissociation of hydrogen (104.20 kcal) and fluorine (37.72 kcal), and the enthalpy of formation of methane (-17.90 kcal) were used to calculate the enthalpy of formation of gaseous CH_3F. These authors measured an appearance potential for CH_3^+ from CH_3F of 14.6 ± 0.6 eV, which would give an uncertainty of about ±15 kcal mol^{-1} in the enthalpy of formation of methyl fluoride. However, a correlation of the enthalpy of formation from the atoms of the methyl fluorides and methyl chlorides indicates that the uncertainty can be reduced to ± 7 kcal mol^{-1}.

Heat Capacity and Entropy

Fundamental vibrational frequencies were taken from the summary reported by Smith and Mills (2). Moments of inertia from the microwave results of Gilliam, Edwards, and Gordy (3) are: $I_A = 0.5354 \times 10^{-39}$, $I_B = I_C = 3.3093 \times 10^{-39}$ g, cm^2. Bond parameters are the vlaues of Brockway, Thornton, and Bartell (4) from electron diffraction results. These values are in close agreement with the microwave parameters reported by Gilliam, Edwards, and Gordy (3).

Ground State Quantum Weight: 1 $\sigma = 12$
Point Group: T_d
Bond Distance: C-H = 1.091 ± 0.002 Å
Bond Angle: H-C-H = 109.4712°
Product of the Moments of Inertia: $I_A I_B I_C = 1.499 \times 10^{-118}\ g^3\ cm^6$.

Enthalpy of Formation

Rossini (1) measured the enthalpy of combustion of methane gas. His value at 298.15 K was corrected to the presently accepted molecular weight of water. The enthalpy of formation was calculated using -68.3174 and -94.0540 kcal mol^{-1} for the enthalpy of formation of $H_2O(\ell)$ and $CO_2(g)$, respectively.

Heat Capacity and Entropy

Stevenson and Ibers (2), calculated the bond distance from an analysis of available spectroscopic data. Vibrational frequencies listed by Jones and McDowell (3), are consistent with their results of a force constant calculation. The principal moments of inertia are: $I_A = I_B = I_C = 0.5313 \times 10^{-39}\ g\ cm^2$.

CYANOGEN IODIDE (ICN) IDEAL GAS M_r = 152.9222

$S°(298.15\ K) = 257.34 \pm 0.04\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 226.5 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 225.9 \pm 6.3\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
485.8 (1)
304.5 (2)
2188 (1)

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: $C_{\infty V}$

Bond Distances: C-I = 1.994 Å C-N = 1.159 Å

Bond Angle: I-C-N = 180°

Rotational Constant: $B_0 = 0.107604\ cm^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from $\Delta_f H°$(ICN, cr, 298.15 K) = 39.71 kcal mol^{-1} (1) and $\Delta_{sub} H°(298.15\ K) = 14.29 \pm 0.15$ kcal mol^{-1}. This latter value is obtained from a 2nd and 3rd law analysis of the vapor pressure data of Yost and Stone (2) and Ketelaar and Kruyer (3), which are in good agreement after dropping the lowest point in the first set and the lowest 3 points in the second set.

The enthalpy of formation of the crystal is calculated from $\Delta_r H°(298.15\ K) = -46.3 \pm 0.08$ kcal obtained by Lord and Woolf (4) for the reaction ICN(cr) + 2 NaOH(56 H_2O) = NaCNO(2800 H_2O) + NaI(2800 H_2O) + H_2O(ℓ). The auxiliary data used were $\Delta_f H°$(NaOH·56 H_2O, 298.15 K) = -112.26 kcal mol^{-1} (1, 5); $\Delta_f H°$(NaCNO·2800 H_2O, 298.15 K) = -92.25 kcal mol^{-1} (1, 5) and $\Delta_f H°$(NaI·2800 H_2O, 298.15 K) = -70.54 kcal mol^{-1} (1, 5). The uncertainty in the final value reflects the uncertainty in $\Delta_f H°$(NaCNO·2800 H_2O, 298.15 K) which was determined by Lord and Woolf to be -93.6 kcal mol^{-1} in excess NaOH·56 H_2O.

Enthalpy Reference Temperature = T_r = 298.15 K Standard State Pressure = p° = 0.1 MPa

PREVIOUS: June 1969 (1 atm) CURRENT: June 1969 (1 bar)

POTASSIUM CYANIDE (KCN) CRYSTAL M_r = 65.1160

$S°(298.15\ K) = 127.780 \pm 1.05\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 168.3 \pm 0.1\ K$
$T_{fus} = 895 \pm 2\ K$

$\Delta_f H°(0\ K) = -118.34 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -113.47 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 1.167\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 14.644\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy change, $\Delta_r H°(298.15\ K) = 2.80 \pm 0.10\ kcal\ mol^{-1}$, for the reaction KCN(cr) + KCN(aq, ∞) was reported by Parker (1). Incorporating these data with the enthalpy of formation for K^+(aq, ∞) and CN^-(aq, ∞), reported by Wagman et al. (2), the value of $\Delta_f H°$(KCN, cr, 298.15 K) was evaluated to be $-27.12 \pm 0.2\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The heat capacity for KCN(cr) has been measured with a heat conduction method by Messer and Ziegler (3), 101.6-345.8 K, and adiabatically by Suga et al. (4), 14.23-308.5 K. The data of Suga (4) were adopted after correction for curvature. The anomaleous region between 50-105 K has been treated as second order by inclusion of the enthalpy in the heat capacity. The $C°_p$ values above 310 K were estimated by graphical extrapolation. The value of S°(298.15 K) was evaluated based on S°(15 K) = $0.193\ cal\ K^{-1}\ mol^{-1}$. This extrapolated value appears more reasonable than the value, S°(15 K) = $0.307\ cal\ K^{-1}\ mol^{-1}$ reported by Suga et al (4).

Transition Data

T_{trs} was taken from Suga et al (4). $\Delta_{trs} H°$ was calculated as the difference between the total enthalpy change, H°(173.80 K) - H°(159.02 K) = $0.533\ kcal\ mol^{-1}$ obtained from $C°_p$ values measured by Messer and Ziegler (3), and the enthalpy change, $0.254\ kcal\ mol^{-1}$, calculated from the arbitrarily smoothed $C°_p$ curve. Suga et al (4) reported $\Delta_{trs} H° = 0.339\ kcal\ mol^{-1}$; however, their $C°_p$ data do not adequately define the total enthalpy change through the transition region. The values of T_{trs} and $\Delta_{trs} H°$ reported by Messer and Ziegler (3) were 168.3±0.4 K and $0.30\ kcal\ mol^{-1}$, respectively. The lower transition, $T_{trs} = 82.9 \pm 0.2$ K and $\Delta_f H° = 0.095 \pm 0.001\ kcal\ mol^{-1}$ reported by Suga et al. (4) was treatment as second order by inclusion of the enthalpy in the heat capacity.

Fusion Data

See the liquid table for details.

Sublimation Data

The difference between $\Delta_f H°(298.15\ K)$ for $(KCN)_2$(g) and 2 KCN(cr) is $\Delta_{sub} H°$(cr → dimer, 298.15 K) and for KCN(g) and KCN(cr) is $\Delta_{sub} H°$(cr → monomer, 298.15 K).

PREVIOUS: June 1962 CURRENT: March 1966

POTASSIUM CYANIDE (KCN) LIQUID M_r = 65.1160

$S°(298.15\ K) = [134.321]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 895 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-104.148]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 14.644\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(895\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Heat capacity is *estimated* and assumed constant in the temperature range 298.15-3000 K. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting temperature was reported by Truthe (1). The value of $\Delta_{fus} H°$ was taken from Kelly (2) on phase diagrams of the systems KCN-AgCN, KCN-$Cu_2(CN)_2$, KCN-KCl, KCN-NaCN, and KCN-$Zn(CN)_2$ reported by Truthe (1).

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change for the reaction KCN(ℓ) = KCN(g) *becomes zero*. The difference between $\Delta_f H°$ for KCN(g) and KCN(ℓ) at T_{vap} is $\Delta_{vap} H°$.

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: $C_{\infty v}$

Bond Distances: C-N = 1.16 ± 0.01 Å K-C = [2.294] Å

Bond Angle: K-C-C = 180°

Rotational Constant: B_o = [0.118914] cm^{-1}

Enthalpy of Formation

The vapor pressure of KCN(g) at 870°C was estimated to be 1-10 mm Hg by Villars (1). Assuming the vapor pressure at this temperature to be 1 mm Hg, the enthalpy of vaporization, $\Delta_{vap}H°(298.15\ K)$, for KCN(ℓ) was evaluated as 44 kcal mol^{-1}. Based on $\Delta_f H°(298.15\ K) = -24.89$ kcal mol^{-1} for KCN(ℓ), the value of $\Delta_f H°$(KCN, g, 298.15 K) is calculated to be 19 ± 5 kcal mol^{-1}.

Heat Capacity and Entropy

The molecular structure of KCN(g) has not been determined. It was assumed to be linear by comparison with that for HCN(g). The C-N bond distance was determined by Elliott and Hastings (2) by use of neutron diffraction measurements. The K-C bond distance was taken from Leroi (3), which was estimated. The vibrational frequencies, ν_2 and ν_3, were obtained from Leroi and Klemperer (4). The value of ν_1 was calculated by valence force method described by Herzberg (5) using appropriate force constants.

POTASSIUM CARBONATE (K_2CO_3) CRYSTAL M_r = 138.2058

$S°(298.15\ K) = 155.519 \pm 0.4\ J\ K^{-1}mol^{-1}$

$T_{fus} = 1174 \pm 1\ K$

$\Delta_f H°(0\ K) = -1144.61 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1150.18 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 27.614 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was obtained from the enthalpy of solution $\Delta_\infty H° = -7.6 \pm 0.5$ kcal mol^{-1} and the enthalpies of formation for $K^+(aq)$ and $CO_3^{--}(aq)$, -60.32 and -161.84 kcal mol^{-1}, respectively. The standard enthalpy solution, $\Delta_\infty H° = -7.6 \pm 0.5$ kcal mol^{-1}, was calculated by extrapolation to infinite dilution of the calorimetric data of Benjamin (1), using the methods suggested by Rupert et al. (2). The equilibrium constant for the hydrolysis $CO_3^{--}(aq, \infty) + H_2O(\ell) + HCO_3^-(aq, \infty) + OH^-(\infty H_2O)$ was taken as K -2.1 x 10^{-4} based on the selected values of Wagman et al. (3). The resulting extrapolations were not so consistent as those of Rupert et al. (2) for Na_2CO_3. The ionic enthalpies of formation were taken from Wagman et al. (3). This procedure was adopted even though it may involve an inconsistency between the extrapolations for $\Delta_\infty H°$ and $CO_3^{--}(\infty H_2O)$. The alternative evaluation of $\Delta_f H°(298.15\ K)$ for $K_2CO_3(\sim 1900\ H_2O)$ from the enthalpies of mixing given by Muller (4) and Berthelot (5) may be subject to significant error if dissolved CO_2 was not excluded from the solutions. Presumably, this path was used by Wagman (6) in the selection of $\Delta_f H°(298.15\ K) = -274.3$ kcal mol^{-1}. This value is 0.6 kcal mol^{-1} less negative than the value adopted here.

Heat Capacity and Entropy

The low temperature heat capacity, 14.0-315 K was measured by Oetting (7). Janz et al. (8) measured the heat content by drop calorimetry in the temperature range 630-1250 K, and gave enthalpy and heat capacity equations based on their measurements. The above information was used in a Shomate analysis in order to smooth the enthalpy and calculate heat capacity above 298.15 K. The values from the low and high temperature sources join smoothly at 298.15 K. The heat capacity was graphically extrapolated above the melting point. The entropy at 14.0 K was calculated from the extrapolated low temperature C_p° data, using the cubic law. The value of $S°(14\ K) = 0.109$ cal $K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} was obtained from Reisman (9) and $\Delta_{fus} H°$ was taken from Janz (8).

PREVIOUS: December 1961 CURRENT: March 1966

POTASSIUM CARBONATE (K_2CO_3) LIQUID M_r = 138.2058

$S°(298.15\ K) = [170.373]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1174 \pm 1\ K$

$\Delta_f H°(298.15\ K) = [-1130.609]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 27.614 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1174\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 800 K. The heat capacity below 800 K is obtained from the heat capacity of the crystal. Above 800 K the heat capacity is adopted as 50.0 cal K^{-1} mol^{-1}, based on the enthalpy measurements in the range 1169-1250 K reported by Janz et al. (1). The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

PREVIOUS: CURRENT: March 1966

$S°(298.15\ K) = 90.171 \pm 0.21\ J\ K^{-1}\ mol^{-1}$
$T_{trs1} = 623\ K$
$T_{trs2} = 683 \pm 3\ K$
$T_{fus} = 993 \pm 1\ K$

$\Delta_f H°(0\ K) = -1207.891 \pm 0.17\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1216.038 \pm 0.17\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = [0.561]\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = [2.238]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 44.769 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was derived from the enthalpy change of the following reactions:

	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	References
$2\ Li^+(aq, \infty) + CO_3^{--}(aq, \infty) = Li_2CO_3(cr)$	4.20	[1]
$2\ Li(cr) + 2\ H_2O(l) = 2\ Li^+(aq, \infty) + 2\ OH^-(aq, \infty) + H_2(g)$	-106.310	[2][3][4][5]

Summation of these two reactions gives

$2\ Li(cr) + 2\ H_2O(l) + CO_3^{--}(aq, \infty) = Li_2CO_3(cr) + 2\ OH^-(aq, \infty) + H_2(g)$ -102.110

Using $\Delta_f H°$ (6) of $H_2O(l)$, $CO_3^{--}(aq, \infty)$ and $OH^-(aq, \infty)$ yields $\Delta_f H°$ (Li_2CO_3, cr, 298.15 K) = -290.64 kcal mol^{-1}.

Heat Capacity and Entropy

The low temperature heat capacity, 16.68-300.20 K, was measured by Brown and Latimer (1). Janz et al. (7) measured the heat content by drop calorimetry in the temperature range 560-1150 K and gave enthalpy and heat capacity equations based on their measurement. The above information was used in a Shomate analysis in order to smooth the enthalpy and calculate heat capacity. The values from the low and high temperature sources join smoothly at 298 K. The heat capacity was graphically extrapolated above the melting point. The entropy at 16.68 K was calculated from the extrapolated low temperature $C_p°$ data, using the cubic law. The value of S°(16.68 K) = 0.053 cal K^{-1} mol^{-1}.

Transition Data

T_{trs} were taken from Reisman (8). The enthalpies of transition were estimated from the relative areas of the transitions and the heat of fusion of the differential analysis curve reported by Reisman (8).

Fusion Data

T_{fus} was obtained from Reisman (8) and $\Delta_{fus} H°$ was taken from Janz et al. (7).

PREVIOUS: CURRENT: March 1966

LITHIUM CARBONATE (Li_2CO_3) LIQUID M_r = 73.8912

$S°(298.15\ K)$ = [130.567] J K^{-1} mol^{-1}

T_{fus} = 993.15 ± 1 K

$\Delta_f H°(298.15\ K)$ = [-1175.083] kJ mol^{-1}

$\Delta_{fus} H°$ = 44.769 ± 0.4 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(993.15\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 683.15 K. The heat capacity below 683.15 K is obtained from the heat capacity of the crystal. Above 683.15 K the heat capacity is adopted as 44.32 cal deg^{-1} mol^{-1}, based on the enthalpy measurements in the range 996-1150 K reported by Janz et al. (1). The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Lithium Carbonate (Li_2CO_3) $C_1Li_2O_3$(cr,1)

$S°(298.15\ K) = 65.854\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -1104.3 \pm 8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1111.7 \pm 8\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -265.7 \pm 2\ kcal\ mol^{-1}$ ($-1111.689 \pm 8\ kJ\ mol^{-1}$) is the average value derived from the dissociation pressures of $MgCO_3(cr)$ in the temperature range 671-782 K measured by Marc (1) and from the $\Delta_r H°(923\ K) = 25.9 \pm 0.6\ kcal\ mol^{-1}$ determined by Thomasson and Cunningham (2) using a high temperature differential calorimeter. The decomposition of $MgCO_3$ has been studied in a bomb calorimeter by Roth (3); this yields $\Delta_r H°(293\ K) = 23.8\ kcal\ mol^{-1}$ when corrected to constant pressure. The value is derived from the small difference between two large heats of combustion, so the uncertainty is probably large. Roth also reported $\Delta_r H°(363\ K) = 26.15\ kcal\ mol^{-1}$ from calorimetric data on the heat of solution in HCl. Berthelot (4) measured the heat of solution of $MgSO_4(aq)$ with $K_2CO_3(aq)$. Analyzing his data we find $\Delta_f H°(298.15\ K) = -268.6\ kcal\ mol^{-1}$.

Discrepancies are apparent in the wide range of the calorimetric results and in the 3rd law drift of the equilibrium data. Possible sources for the drift include lack of true equilibrium (e.g., excess surface energy for MgO) and uncertainty in the high temperature entropy of $MgCO_3$(see entropy write-up). Non-standard state behavior of the crystal phases may also be a problem in the calorimetric studies. The data of Thomasson and Cunningham (2), based on a high temperature differential thermal analysis technique, are probably the most reliable of the calorimetric values; however, there are uncertainties in the absolute energy calibration. The first result of Roth (3) may be dismissed as too discrepant and the remaining two calorimetric values are within ±3 kcal of the selected enthalpy of formation.

Source	Method	Reaction	T/K	$\Delta_r H°(298.15\ K)$ kcal mol		Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Marc (1)	Kp	$MgCO_3(cr) = MgO(cr) + CO_2(g)$	671-782	-	28.3	4.8 ± 0.9	-266.04
Thomasson	Calorimetric	$MgCO_3(cr) = MgO(cr) + CO_2(g)$	923	25.9	27.7		-265.45
Roth (3)	Calorimetric	$MgCO_3(cr) = MgO(cr) + CO_2(g)$	293	23.8	23.8		-260.35
Roth (3)	Calorimetric	$MgCO_3(cr) = MgO(cr) + CO_2(g)$	363	26.15	26.10		-263.95
Berthelot (4)	Calorimetric	$K_2CO_3(\sim.5m) + MgSO_4(\sim.5m) = MgCO_3(cr) + K_2SO_4(\sim.5m)$	288	1.05	1.35		-268.6

Heat Capacity and Entropy

Low temperature heat capacities (56.3 - 291.6 K) were measured by Anderson (5). The high temperature heat capacities are derived by a Shomate analysis of smoothed enthalpies reported by Kelley (6). Kelley obtained the smoothed values from unpublished high temperature (400-743 K) enthalpy measurements by Shomate (7). The data were joined smoothly at 298.15 K and extrapolated graphically above 743 K. The entropy was obtained from the heat capacities using $S°(56.2) = 0.57\ cal\ K^{-1}\ mol^{-1}$.

Because of the drift in the decomposition pressure data, it is pertinent to assess the uncertainty in the functions. The greatest potential source for error is in the values above room temperature where the increment of entropy is about 20 cal K^{-1} mol^{-1} between 298.15 and 700 K. Unfortunately, no evaluation of the unpublished enthalpies is possible, but an increase of 10% in the entropy increment would reduce the drift to a tolerable level.

Decomposition Data

T_{dcm} is calculated as the temperature at which $\Delta_r G°$ equals zero for $MgCO_3(cr) = MgO(cr) + CO_2(g)$.

Enthalpy of Formation

The enthalpy of formation of CN has been the subject of considerable uncertainty for many years. Berkowitz (1) has reviewed the earlier work and he concludes that $\Delta_f H°(CN, g, 0\ K) = 109\ kcal\ mol^{-1}$. Since this review a considerable body of work has emerged which supports a value near 100 kcal mol^{-1}.

Tsang et al. (2) obtained $\Delta_f H°(CN, g, 298.15\ K) = 100 \pm 4\ kcal\ mol^{-1}$ from shock tube studies of the decomposition of cyanogen.

Dibeler and Liston (3, 4) have studied a series of cyanogen compounds and obtained their enthaplies of dissociation from photoionization threshold measurements. The values below are obtained from the halogen ion threshold measurements, except for HCN which is from the CN^+ threshold measurements. The value below is calculated using the IP from CNCl measurements (3).

Davis and Okabe (5) employed a direct photodissociation technique to obtain dissociation energies for many of the same molecules. The method determines the disappearance threshold for fluorescence due to decay of excited CN $B^2\Sigma^+ - X^2\Sigma^+$. This corresponds to the energy needed to just break the bond and form excited cyanogen in the $B^2\Sigma^+$ state, whose energy above ground is well known.

Setser and Steadman (6) used metastable excited argon atoms with a maximum electronic energy of 270 kcal mol^{-1} to break the bonds in HCN and $(CN)_2$. From the emission spectra of the excited $B^2\Sigma^+$ CN they were able to calculate the highest populated vibrational level and thus a maximum limit to the dissociation energy.

Berkowitz et al. (7) have recently examined the photoionization spectrum of HCN using the H^+ ion threshold. They also determined the threshold for the CN^+ ion which agrees exactly with that of Diebeler and Liston (4) when the latter is corrected for rotational energy contributions (0.7 kcal). Berkowitz et al. (7) suggest that the HCN limit of Setser and Steadman (6) should be ≤105 due to neglect of the significant vibrational population of the first harmonic of the bending mode. However, if the same allowance is made for the C_2N_2 data the limit is only ≤104 and this presumes significant occupation of the third harmonic of the bending mode of C_2N_2.

It is apparent from the data that considerable scatter still exists and several sources of error are probable. HCN and the cyanogen halides all have significant uncertainties in their enthalpy of formation, and the effects of rotational and vibrational contributions at 300 K are uncertain, but could be eliminated by using refrigerated gases. We choose to adopt a median value within the range of almost all determinations of $\Delta_f H°(CN, g, 0\ K) = 103.2 \pm 2.5\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The therodynamic functions are taken from Johnston et al. (8) calculated based on the direct summation of the energy levels. All the electronic levels and molecular constants listed above are from Carroll (9). Johnston et al. used only the first two excited electronic states but the contribution of the higher levels is negligible.

CYANOGEN, ION (CN^+) IDEAL GAS M_r = 26.01715

$S°(298.15\ K) = 213.44 \pm 6.3\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1793.26 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 1802.76 \pm 12.6\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	[6]
[1500]	[1]
[6000]	[2]
[8000]	[3]
[15000]	[2]

ω_e = [1580] cm^{-1} $\omega_e x_e$ = [12.5] cm^{-1} σ = 1

B_e = [1.566] cm^{-1} α_e = [0.017] cm^{-1} r_e = [1.29] Å

Enthalpy of Formation

Dibeler and Liston (1) have measured the photoionization thresholds for the processes:

$ClCN + h\nu \rightarrow Cl^+ + CN + e^-$ $\Delta_r H°(0\ K) = 399.44 \pm 0.5$ kcal

$ClCN + h\nu \rightarrow Cl + CN^+ + e^-$ $\Delta_r H°(0\ K) = 426.65 \pm 0.5$ kcal

By subtraction we obtain

$Cl + CN^+ \rightarrow Cl^+ + CN$ $\Delta_r H°(0\ K) = -27.21 \pm 0.7$ kcal

Using JANAF vlaues for Cl, Cl^+ and CN we obtain $\Delta_f H°(CN^+, 0\ K) = 430.6 \pm 3.0$ kcal mol^{-1} and IP(CN) = 327.42 ± 0.7 kcal mol^{-1}.

Berkowitz et al. (2) have measured the photoionization thresholds for the processes:

$HCN + h\nu \rightarrow H^+ + CN + e^-$ $\Delta_r H°(0\ K) = 438.18 \pm 0.3$ kcal

$HCN + h\nu \rightarrow H + CN^+$ $\Delta_r H°(0\ K) = 448.09 \pm 0.3$ kcal

By subtraction we obtain

$H + CN^+ \rightarrow H^+ + CN$ $\Delta_r H°(0\ K) = -9.91 \pm 0.4$ kcal

Using JANAF values for H, H^+ and CN we obtain $\Delta_f H°(CN^+, 0\ K) = 426.7 \pm 3.0$ kcal mol^{-1}, and IP(CN) = 323.51 ± 0.4 kcal mol^{-1}.

We adopt a median value for $\Delta_f H°(CN^+, 0\ K) = 428.6 \pm 3.0$ kcal mol^{-1} and 325.4 ± 2 kcal mol^{-1} for IP(CN).

Heat Capacity and Entropy

The molecule has eight valence electrons and thus we expect that its molecular constants should fall between those for C_2 and BN. The ground electronic state is either $^1\Sigma$ or $^3\Pi$ and the two levels are likely to be very close. As a consequence the thermodynamic functions are dominated by the $^3\Pi$ contribution and so we choose this to be the ground state. The other levels are estimated based on the values of Fougere and Nesbet (3) for C_2 and of Verhaegen et al. (4) for BN. The vibrational constants and bond length are estimated between those for the $^3\Pi$ states of BN and C_2. The rotational constants B_e is obtained from the estimated bond length and α_e is calculated from the other constants assuming a Morse potential function.

State	ϵ_i, cm^{-1}	g_i
[$^1\Sigma^+$]	0	[1]
	[67000]	[2]

ω_e = [2250] cm^{-1} $\omega_e x_e$ = [13.8] cm^{-1} σ = 1
B_e = [2.116] cm^{-1} α_e = [0.0177] cm^{-1} r_e = [1.11] Å

Enthalpy of Formation

Berkowitz et al. (1) reported 88 ± 0.5 kcal mol^{-1} for the electron affinity of CN from the photoionization thresholds of the reactions $HCN \rightarrow N^+ + CN^-$ and $HCN \rightarrow H^+ = CN + e^-$.

Other values have been reported by Page (2), who reinterpreted his earlier data (3), to yield 73 ± 1 kcal mol^{-1}; Bakulina and Ionov (4) in conjunction with the data of Branscomb and Smith (5) reported 78 ± 5 kcal mol^{-1} and Inoue (6) who obtained 83 ± 7 kcal mol^{-1}.

We adopt the value given by Berkowitz et al. (1) as being the most well defined in terms of both the precision of measurements and the reactions being studied. This leads to $\Delta_f H°(CN^-, g, 0\ K)$ = 15.2 ± 3 kcal mol^{-1} or $\Delta_f H°(CN^-, g, 298.15\ K)$ = 14.5 ± 3 kcal mol^{-1}.

Heat Capacity and Entropy

The electronic structure and molecular constants are estimated by analogy with the isoelectronic species CO and N_2. The uncertainties in the constants are generally small since N_2 and CO are quite similar, thus the entropy has an uncertainty of only 0.5 cal K^{-1} mol^{-1}.

PREVIOUS: December 1970 (1 atm) CURRENT: December 1970 (1 bar)

SODIUM CYANIDE (NaCN) CRYSTAL M_r = 49.00747

$S°(298.15\ K) = [118.47 \pm 2.1]\ J\ K^{-1}mol^{-1}$

T_{fus} = 835 K

$\Delta_f H°(0\ K) = -98.3 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -90.7 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [8.786]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy change for the reaction NaCN(cr) + NaCN(aq, ∞) was reported to be 0.29 ± 0.20 kcal mol^{-1} by Parker (1). Incorporating this data with the heats of formation for Na^+(aq, ∞), -57.39, and CN^-(aq, ∞), 36.0 kcal mol^{-1}, reported by Wagman et al. (2), the value of $\Delta_f H°(298.15\ K)$ for NaCN(cr) was derived and adopted.

Lord and Woolf (3) determined the value, $\Delta_f H°$(NaCN, cr, 298.15 K) = -21.4 kcal mol^{-1}, by solution calorimetry. This value is in agreement with the adopted one.

Heat Capacity and Entropy

The low temperature heat capacities, 101.6-345.8 K, were reported by Messer and Ziegler (4). The $C_p°$ values above 345.8 K were estimated by graphical extrapolation. S°(298.15 K) was derived from low temperature heat capacities, based on S°(100 K) = 8.4 cal deg^{-1} mol^{-1} which was estimated by comparison with the S°(298.15 K) values for NaCl, KCl, and KCN crystals.

Transition Data

The transition temperatures, T_{trs_2} and T_{trs_1}, were determined by Messer and Ziegler (4). The corresponding enthalpies of transition were reported to be 0.15 and 0.70 kcal mol^{-1}, respectively. However, these quantities were incorporated with $C_p°$ values used to evaluate H°(0 K) - H°(298.15 K). Therefore $\Delta_{trs}H°$ values are not listed.

Fusion Data

See the liquid table for details.

Sublimation Data

The difference between $\Delta_f H°(298.15\ K)$ for $(NaCN)_2$(g) and 2 NaCN(cr) is $\Delta_{sub}H°$(cr → dimer, 298.15 K); for NaCN(g) and NaCN(cr) is $\Delta_{sub}H°$(cr→ monomer, 298.15 K).

PREVIOUS: December 1960 CURRENT: March 1966

SODIUM CYANIDE (NaCN) LIQUID M_r = 49.00747

$S°(298.15\ K)$ = [125.507] J K^{-1} mol^{-1}

T_{fus} = 835 K

$\Delta_f H°(298.15\ K)$ = [-84.398] kJ mol^{-1}

$\Delta_{fus} H°$ = [8.7] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ was obtained from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(835 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for NaCN(cr), KCN(cr) and KCN(ℓ). A glass transition temperature is assumed at 600 K. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting temperature was reported by Truthe (1). $\Delta_{fus} H°$ is estimated such that the derived third law value for $\Delta_{vap} H°(NaCN, \ell)$ agrees with the 2nd law value. See the ideal gas table for details.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change for the reaction NaCN(ℓ) = NaCN(g) becomes zero. The difference between $\Delta_f H°$ for NaCN(g) and NACN(ℓ) at T_{vap} is $\Delta_{vap} H°$.

Bond Angle: Na-C-N = [180]°

Rotational Constant: B_o = [0.182724] cm^{-1}

Enthalpy of Formation

The vapor pressures of NaCN(ℓ) at temperatures 805-1353 K were measured by Ingold (1). According to the investigation reported by Porter (2), the vapor consists of NaCN and $(NaCN)_2$. Based on his data the dimer/monomer ratios at temperatures 805-1353°C(1078.2-1626.2 K) were calculated to be 0.29-0.09. Hence the respective partial pressures for NaCN(g) and $(NaCN)_2$)(g) were derived. By the 2nd and 3rd law methods, the values of $\Delta_{vap}H°$(ℓ → monomer, 298.15 K) were evaluated to be 43.43 and 42.69 kcal mol^{-1}, respectively. The enthalpy of formation for NaCN(g) is calculated from $\Delta_f H°$(NaCN, cr, 298.15 K) and the 3rd law value for $\Delta_{vap}H°$.

Heat Capacity and Entropy

The molecular structure of NaCN(g) has not been determined. It was assumed to be linear by comparison with that for HCN(g). The C-N bond distance was assumed to be the same as that in KCN(g) and the Na-C bond distance was taken from Leroi (3), which was calculated. The vibrational frequencies, ν_2 and ν_3, were measured by Leroi and Klemperer (4) from infrared absorption spectra. The value of ν_1 was calculated by valence force method described by Herzberg (5), using appropriate force constants.

Enthalpy of Formation

Okabe (1) has measured the onset of photodissociation for the process HNCO(g) + H(g) + NCO($A^2\Sigma$) as 7.73 ± 0.01 eV (178.25 ± 0.25 kcal). This result in combination with JANAF auxiliary data (2) results in $\Delta_f H°(NCO, g, 0\ K) = 38 \pm 2.5$ kcal mol^{-1}.

Dixon (3) has discussed the diffusencess in the $^2\Pi$-$^2\Pi$ bands of NCO above 33700 cm^{-1} and concludes this is due to either predissociation or unresolved groups of lines due to a perturbing state. Assuming the dissociation is to N(^{2}D) + CO($^1\Sigma$) yields D_0^0(N-CO) ≤ 41 kcal, or $\Delta_f H°(NCO, 0\ K) \geq 44$ kcal mol^{-1}; assuming the products CN($^2\Sigma$) + O(^{3}P) then D_0^0(NC-O) ≤ 97 kcal, or $\Delta_f H°(NCO, 0\ K) \geq 65$ kcal mol^{-1}. Milligan and Jacox (4) confirm the diffuseness and observe increased amounts of CO. Thus, they prefer the first dissociation mechanism which favors $\Delta_f H°(NCO, 0\ K) \geq 44$ kcal mol^{-1}. An upper limit to the enthalpy formation can be obtained from HNCO(g) (2) by assuming a maximum D_0^0(H-NCO) ≤ 122 kcal, equal to D_0^0(H-CN), which yields $\Delta_f H°(NCO, 0\ K) \leq 45$ kcal mol^{-1}. Another estimate may be obtained by making the reasonable assumption that the sum of the atomization energies of NCN + NNO equal those of NNN + NCO, where the central atoms are simply interchanged. Using respective atomization values (2) of 282, 264 and 242 kcal yields 304 kcal for NCO, or $\Delta_f H°(NCO, 0\ K) = 38$ kcal mol^{-1}. It appears that the diffuseness in the spectrum is not due to predissociation, since all the estimates and measurements fall below the vlaues calculated on that basis. We adopt $\Delta_f H°(NCO, g, 0\ K) = 38 \pm 2.5$ kcal mol^{-1}.

Heat Capacity and Entropy

The electronic levels, structure, and ν_2 are from Dixon (3). The ν_1 and ν_3 vibrational frequencies are from the matrix isolation data of Milligan and Jacox (4). The individual bond lengths are those selected by Milligan and Jacox (4) to fit the overall length determined by Dixon (3).

Enthalpy of Formation

The enthalpy of formation is calculated from the estimated enthalpy of reaction $\Delta_r H°(0\ K) = 255 \pm 30$ kcal mol^{-1} for CNN(g) + C(g) + 2 N(g). Since CNN radical can dissociate to give C + N_2 or CN + N, the molecule must have more energy than either CN or N_2. It is assumed that the extra bond will be quite weak, for this we estimate 30±30 kcal mol^{-1} which gives $\Delta_r H°(0\ K) = 255 \pm 30$ kcal mol^{-1} (583.856±126 kJ mol^{-1}) for the first path and $\Delta_r H° = 204 \pm 30$ kcal mol^{-1} for the second. We adopt the former value.

Heat Capacity and Entropy

Milligan and Jacox (1) have measured three fundamental vibrational frequencies for CNN radical (g) in the infrared and ultraviolet spectra by matrix-isolation, and proposed a linear molecular configuration with a $^3\Sigma$ ground state which has been confirmed by Wasserman et al. (2) in the electron paramagnetic resonance observations. Also Milligan and Jacox (1) suggested a "C≡N=N" bond structure, based on the agreement between the C-N and N-N stretching force constants (calculated from observed vibrational frequencies in the CNN radical) and the typical C≡N and N=N stretching force constants. In addition, they estimated the bond distances r(C-N) = 1.15 Å and r(N-N) = 1.25 Å from the proposed structure.

Point Group: $D_{\infty h}$ $\sigma = 2$

Bond Distance: C-N = 1.232 Å

Bond Angle: N-C-N = 180°

Rotational Constant: $B_0 = 0.396469\ cm^{-1}$

Enthalpy of Formation

Okabe and Mele (1) have measured the photodissociation onset of the process

$$CN{\cdot}N_3(g) + NCN(g) + N_2(A^3\Sigma) \qquad \Delta_r H°(0\ K) = 149.3 \pm 2.5\ kcal$$

Using $\Delta_f H°(N_2, A^3\Sigma, 298.15\ K) = 143.5\ kcal\ mol^{-1}$ (2) and $\Delta_f H°(CN{\cdot}N_3, g, 298.15\ K) = 107 \pm 3\ kcal\ mol^{-1}$ (3), we obtain $\Delta_f H°(NCN, g, 298.15\ K) = 113 \pm 5\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The X and A electronic levels, ground state structure, and rotational constants are from Herzberg and Travis (4), the $a^1\Delta$ level is estimated from the work of Schoen (5). The vibrational frequencies have been observed in the matrix-isolated species by Milligan and Jacox (6, 7). Wasserman et al. (8) have confirmed the ground state is linear and triplet by electron paramagnetic resonance.

Enthalpy of Formation

The enthalpy of formation was obtained from the enthalpy of solution $\Delta_{sol}H = -6.36$ kcal mol^{-1} and the enthalpies of formation for $Na^+(aq, \infty)$ and $CO_2^{--}(aq, \infty)$, -57.39 and -161.84 kcal mol^{-1}, respectively. The enthalpy of solution was taken from Rupert et al. (1). The ionic enthalpies of formation were taken from Wagman et al. (2).

A value of $\Delta_f H°(298.15\ K) = -270.9$ kcal mol^{-1} has been selected by Wagman (3).

Heat Capacity and Entropy

The low temperature heat capacities, 54.6-292.1 K, were measured by Anderson (4). In the temperature range 473.15-873.15 K, Popov and Galchenko (5) measured the heat capacities (by heat conduction calorimetry) and observed two transformations, one at about 623 K and the other at about 750 K. Popov and Ginzburg (6) measured enthalpies in the temperature range 480-1350 K and tabulated their data only in the range 476-872 K. Ginzburg (7) has given heat capacity equations based on the data from (5, 6) and has tabulated thermodynamic functions in the range 500-1500 K. There appear to be inconsistencies among the data, equations and functions. Rolin and Recapet (8) also measured the enthalpy in the temperature range 645-1322 K. Janz et al. (9) have given an enthalpy equation based on their heat content measured data in the range 707-1127 K. May (10) has tabulated smoothed measured enthalpy values in the range 400-1500 K. All the above information was used in a Shomate analysis in order to smooth the enthalpies and calculate heat capacities. The values from the low and high temperature sources join smoothly at 298 K. The heat capacity was graphically extrapolated above the melting point.

The entropy was calculated at 54.60 using the Debye and Einstein function D(138/T) + 2E(266/T) + 2D(737/T) given by Anderson (4). The value of S°(54.6 K) = 3.943 cal deg^{-1} $mole^{-1}$.

Transition Data

T_{trs} was taken from Ginzburg [7] and $\Delta_{trs}H°$ was obtained from the above reported enthalpy measurements by means of Shomate function analysis. The heat of transition at 593.15 K has been incorporated in the heat capacity.

Fusion Data

T_{fus} was taken from Ginzburg [7] and $\Delta_{fus}H°$ was obtained from the above reported enthalpy measurements by means of Shomate function analysis.

PREVIOUS: December 1960 CURRENT: March 1966

SODIUM CARBONATE (Na_2CO_3) LIQUID M_r = 105.98874

$S°(298.15\ K)$ = [156.423] J K^{-1} mol^{-1}

T_{fus} = 1123.15 K

$\Delta_f H°(298.15\ K)$ = [-1108.515] kJ mol^{-1}

$\Delta_{fus} H°$ = 29.665 kJ mol^{-1}

Enthalpy of Formation

The $\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1123.15\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 723.15 K. The heat capacity below 723.15 K is obtained from the heat capacity of the crystal. Above 723.15 K the heat capacity is adopted as 45.30 cal K^{-1} mol^{-1}, *based on the* enthalpy measurements in the range 1127-1210 K reported by Janz, et al. [1]. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

$S°(298.15\ K) = 197.65 \pm 0.04\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -113.81 \pm 0.17\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -110.53 \pm 0.17\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i cm^{-1}	g_i
$^1\Sigma$	0	1

$\omega_e = 2169.52\ cm^{-1}$ $\omega_e x_e = 13.453\ cm^{-1}$ $\sigma = 1$

$B_e = 1.9302\ cm^{-1}$ $\alpha_e = 0.01746\ cm^{-1}$ $r_e = 1.1281$ Å

Enthalpy of Formation

The enthalpy change $\Delta_r H°(298.15\ K)$ for the reaction: $CO(g) + 1/2\ O_2(g) = CO_2(g)$ was reported to be -67.636 ± 0.029 kcal mol^{-1}, based on molecular weight of CO_2 = 44.010, by Rossini (1). It was recalculated to be -67.638 ± 0.03 kcal mol^{-1}, using molecular weight of CO_2 = 44.011, for internal consistency. From the value of $\Delta_r H°(298.15\ K)$, the enthalpy of formation $\Delta_f H°(298.15\ K)$ for CO(g) was derived to be -26.417 ± 0.04 kcal mol^{-1}, which yields $D_0^0(CO) = 11.09$ eV.

The $D_0^0(CO)$ value has been proposed to be 6.92 to 11.11 eV in the past few decades in order to explain data collected from spectroscopic, flame, shock-wave, detonation, and electron-impact studies. Recent evaluations by Brewer and Searcy (2), Fineman and Petrocelli (3), and Giese and Maier (4) favored the value 11.11 eV, reported by Gaydon (5).

The enthaply of combustion of CO(g) was also determined by Awbery and Griffiths (6), Fenning and Cotton (7), and Roth and Banse (8).

Heat Capacity and Entropy

The functions adopted here were obtained from Belzer et al. (9), assuming the thermodynamic functions for the naturally occurring isotopic mixture to be the same as those for $C^{12}O^{16}(g)$. The spectroscopic constants employed for calculation were reported by Herzberg (10). The tabulated functions include the second order corrections to the rigid-rotator and harmonic-oscillator molecular model for vibrational anharmonicity, rotational stretching and rotational-vibrational interaction.

The spectroscopic constants listed above are for the naturally occurring isotopic composition given by Strominger et al. (11).

Thermodynamic properties for CO from 70 to 300 K, with pressures to 300 atmospheres were reported by Hust et al. (12). Calculations of the vapor pressure and enthalpies of vaporization and sublimation of CO and CO_2 below one atmosphere were reported by Mullins et al. (13).

Ground State Quantum Weight: 1 $\sigma = 1$
Point Group: $C_{\infty v}$
Rotational Constant: $B_{000} = 0.20287\ cm^{-1}$

Spectroscopic constants used in calculating corrections to rigid rotator-harmonic oscillator approximation (cm^{-1}):

$\alpha_1 = 0.0006044$	$X_{11} = -4.0$	$X_{12} = -6.8$	$A_{000} = 0$	$g_{22} = 3.2$
$\alpha_2 = 0.0003539$	$X_{22} = -0.4$	$X_{23} = -11.5$	$C_{000} = 0$	
$\alpha_3 = 0.001838$	$X_{33} = -7.0$	$X_{13} = -4.5$	$D_{000} = 4.37 \times 10^{-8}$	

Enthalpy of Formation

Terres and Wesemann (1), report equilibrium constants from 623 to 873 K for the reaction $CO_2(g) + H_2S(g) \rightleftharpoons COS(g) + H_2O(g)$. These yield $\Delta_r H°(700\ K) = 8.19 \pm 0.23$ kcal, whence $\Delta_f H°(298.15\ K)$ for COS is -33.08 ± 0.25 kcal mol^{-1}. The same authors report equilibrium constants for the reaction $COS(g) + H_2S(g) \rightleftharpoons CS_2(g) + H_2O(g)$, but regard these as less reliable than the others. The resulting value of -26.39 kcal mol^{-1} for $\Delta_f H°(298.15\ K)$ of COS has been disregarded.

Heat Capacity

Gordon (2) has used the constants listed above to calculate $C_p°$ from 298.15 to 6000 K by the method of Pennington and Kobe (3), which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants have been taken from (4, 5, 6, 7, 8). The thermodynamic functions below 298.15 K have been calculated for the rigidly rotating harmonic oscillator.

Bond Angle: O-C-O = 108°

Rotational Constant: $B_0 = 0.391514\ cm^{-1}$

Enthalpy of Formation

The enthalpy change of the reaction C(c, graphite) + O_2(g) = CO_2(g) has been measured by Dewey and Harper (1). Jessup (2), and Prosen and Rossini (3). Based on these data, the enthalpy of formation for CO_2(g) was reported to be -94.0518 ± 0.0108 cal mol^{-1}, using molecular weight of CO_2 = 44.010, by Prosen, Jessup anad Rossini (4). This value was recalculated to be -94.054 ± 0.011 kca mol^{-1}, based on molecular weight of CO_2 = 44.011, for internal consistency.

Heat Capacity and Entropy

The functions adopted here were obtained from Woolley (5), who calculated the thermodynamic functions by means of a direct summation for the naturally occurring isotopic composition. The spectroscopic constants used are essentially those selected by Wentnik (6). Slightly different sets of spectroscopic constants were obtained by Courtoy (7) and Stull, Wyatt and Plass (8). The high-resolution infrared spectrum of O^{18} - enriched CO_2 was examined in the region 5400-1620 cm^{-1}, using an Ebert grating Spectrometer with spectral slit widths ranging from 0.4 to 0.2 cm^{-1} by Berney (9).

The molecular structure was reported by Herzberg (10). The rotational constant, B_0, was obtained from Woolley (5). The value of bond distance, r_e, was calculated from B_e which was derived from B_0, using $B_e - B_0 = 0.0011\ cm^{-1}$ given in Herzberg (10).

Heat capacities of CO_2(g) at high pressures were reported by Vukalovich, Altunin and Gureev (11), Krueger (12) and Vukalovich and Gureev (13).

Bond Distances: C-O = [1.25] Å

Bond Angle: O-C-O = 127° ± 8°

Product of the Moments of Inertia: $I_A I_B I_C = [2.13011 \times 10^{-116}]$

Enthalpy of Formation

$\Delta_f H°(CO_2^-, g, 298.15\ K) = -105.5 \pm 27\ kcal\ mol^{-1}$ is estimated from $\Delta_r H°(298.15\ K) = 88.6 \pm 10\ kcal\ mol^{-1}$ for $HCO_2^-(g) + H(g) + CO_2^-(g)$, using the $\Delta_f H°(HCO_2^-, g, 298.15\ K) = 142 \pm 17\ kcal\ mol^{-1}$ and $\Delta_f H°(H, g, 298.15\ K) = 52.1\ kcal\ mol^{-1}$. The value of $\Delta_r H°(298.15\ K)$ is assumed to be the same as that for HCOOH(g) + H(G) + COOH(g). The values of $\Delta_f H°(HCOOH, g, 298.15\ K)$ and $\Delta_f H°(H, g, 298.15\ K)$, - 90.5 and 52.1 kcal mol^{-1}, respectively, are from NBS (1), and the value of $\Delta_f H°(COOH, g, 298.15\ K) = -54 \pm 3\ kcal\ mol^{-1}$ is from Benson (2). The value of $\Delta_f H°(HCO_2^-, g, 298.15\ K)$ is estimated from an approximate lattice energy calculation for sodium formate. The derived electron affinity of $CO_2(g)$ is 11.5 kcal mol^{-1} (0.5 eV) with an estimated uncertainty range of 0-40 kcal mol^{-1}.

Heat Capacity and Entropy

The correlations of Walsh (3) predict a bent molecular structure of CO_2^- based on its 17 valence electrons. Hartman and Hisatsune (4) measured the asymmetric C-O stretching frequency and derived the bond angle of 127° ± 8° from the infrared spectrum of matrix isolated CO_2^-. They also estimated the bond distance C-O and the symmetric stretching and the bending vibrational frequencies by the valence force method. These molecular constants are adopted in the tabulation. The principal moments of inertia are: $I_A = 0.4511 \times 10^{-39}$, $I_B = 6.6497 \times 10^{-39}$ and $I_C = 7.1008 \times 10^{-39}\ g\ cm^2$.

Ovenall and Whiffen (5) have derived a bond angle of 134° which is in good agreement with the value selected. This result was obtained from electron spin resonance for the CO_2^- radical trapped in sodium formate.

Enthalpy of Formation

We adopt the value which Huber and Herzberg (1) recommended, $D^0_0(CP, g) = 5.28$ eV (509.4 kJ mol^{-1}), based on the mass-spectrometric studies of Gingerich (2), Smoes et al. (3), and Kordis and Gingerich (4). Smoes et al. (3) studied the equilibrium between graphite and mono- and di-atomic phosphorus vapor when gadolinium phosphide was heated in a graphite Knudsen cell in the absence of excess graphite powder (2120-2500 K). Kordis and Gingerich (4) studied the effusate from a graphite-lined tantalum Knudsen cell containing a mixture of graphite(excess)-TiP-Rh.

Heat Capacity and Entropy

The molecular constants for the three electronic states are taken from Huber and Herzberg (1) based on their review in 1976 of the data of Barwald et al. (5), Thakur and Singh (6), Chaudhry and Upadhya (7), and Wentink and Spindler (8).

Enthalpy of Formation

Several values have been proposed for the enthalpy of formation or the dissociation energy of CS(g) (1 - 17). Many of these have been summarized by Hubin-Franksin et al. (16) although distinction was not made between $\Delta_f H°(0\ K)$ and $\Delta_f H°(298.15\ K)$. The values proposed or derivable for $\Delta_f H°(298.15\ K)$ vary from <32 kcal mol^{-1} (electron impact of COS)] to 77±4 kcal mol^{-1} (*photodissociation of COS*, 15) . *We give more weight to the equilibrium measurements* -- $\Delta_f H(298.15\ K) = 69$ kcal mol^{-1} *derived* from (3), 58±5 and 60±6 kcal mol^{-1} (5), 55±1 kcal mol^{-1} (7), and 70±2 kcal mol^{-1} (11) (lack of data prohibits a complete re-analysis of these values) -- and adopt $\Delta_f H°(CS, g, 298.15\ K) = 67 \pm 6$ kcal mol^{-1} (280.328±25 kJ mol^{-1}). This leads to $\Delta_f H°(0\ K) = 66.2 \pm 6$ kcal mol^{-1} and to $D^o_o = 169.1 \pm 6$ kcal mol^{-1} for the process CS(g) = C(g) + S(g), using JANAF values for the heats of formation of C(g) and S(g) (18).

Heat Capacity and Entropy

The molecular constants and electronic levels are those compiled by Rosen (19) except that the value of $\omega_e x_e = 8.46\ cm^{-1}$ given by Rosen (19) and by Suchard (20) appears to be a transcription error for the original $\omega_e x_e = 6.46\ cm^{-1}$ by Lagerqvist, et al. (4).

The microwave spectra of carbon monosulfide have been critically reviewed by Lovas and Krupenie (21). Their derived rotational constants are in agreement with those adopted.

Enthalpy of Formation

Good et al. (1) have determined $\Delta_f H°(CS_2, \ell, 298.15\ K)$ = 21.37±0.17 kcal mol^{-1} by rotating bomb combustion calorimetry. They combined this with an unpublished measurement of $\Delta_{vap}H°(298.15\ K)$ = 6.61±0.02 kcal mol^{-1} to obtain $\Delta_f H°(CS_2, g, 298.15\ K)$ = 27.98±0.19 kcal mol^{-1}. We adopt $\Delta_{vap}H°(298.15\ K)$ = 6.578±0.003 kcal mol^{-1} determined by Weddington et al. (2) by vapor flow calorimetry and obtain the adopted $\Delta_f H°(CS_2, g, 298.15\ K)$ = 27.95±0.20 kcal mol^{-1}.

The resulting $\Delta_f H°(CS_2, g, 0\ K)$ = 27.75±0.20 kcal mol^{-1} leads to $\Delta_a H°(0\ K)$ = 273.33±0.66 kcal mol^{-1} for the process $CS_2(g) = C(g) + 2\ S(g)$. Auxiliary data are from the JANAF Tables (12).

Heat Capacity and Entropy

The fundamental ground state vibrational frequencies are those from a re-analysis of infra-red and Raman spectra by Guenther and Stoicheff, referenced by Kleman (3) as a private communication. Several sets of anharmonicity constants and/or rotational constants have been published (2, 4-9). Some are corrected for Fermi resonance to some degree in some manner (6, 7, 9), others are not (2, 4). We adopt the x_{ii}, x_{ij}, α_i, and g_{22} terms determined from the least-square estimates of the force *constants in the general quartic force field* by Giguere et al. (9). The rotational constants B_e and D_o are from McBride and Gordon (7). The bond distance, r_e, is a rounded average of 1.5529±0.0005 Å (4) and 1.5523±0.0005 Å (5) and is consistent with the adopted B_e. The bond angle of 180° is from Cross and Brockway (10).

Waddington et al. (2) have measured $C°_p$ of carbon disulfide gas in the 325.65-502.25 K range. At 325.65 K, the value calculated by Waddington et al. (2), where Fermi resonance was not considered explicitly, is approximately 0.03% lower than the observed value; at 300 K, the present table is higher than the table calculated by Waddington et al. (2) by about 0.3%. At 502.25 K, the present table is approximately 0.6% higher (0.074 cal K^{-1} mol^{-1}) than the measured value of 12.484 cal K^{-1} mol^{-1}. The value calculated by Waddington et al. (2) is 0.2% higher (0.025 cal K^{-1} mol^{-1}) than the observed value. At 6000 K, the value of $C°_p$ in the present table is approximately 1.1% higher (0.17 cal K^{-1} mol^{-1}) than the value calculated with the anharmonicity constants used by Waddington et al. (2).

The tabulated functions have been generated by the NASA-Lewis computer program (11). We adopted these functions directly for 0 to 298.15 K and reproduce the functions at higher temperatures by integration of $C°_p$.

The allowed error of ±0.02 cal K^{-1} mol^{-1} for S°(298.15 K) includes the values calculated using other anharmonicity correction constants (2, 6, 7).

PREVIOUS: December 1976 (1 atm) CURRENT: December 1976 (1 bar)

SILICON CARBIDE, ALPHA (SiC) CRYSTAL M_r = 40.0965

$S°(298.15\ K) = 16.485 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -70.530 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -71.546 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from $\Delta_r H°(298.15\ K) = -591.9$ kcal mol^{-1} for $SiC(\alpha) + 4F_2(g) \rightarrow SiF_4(g) + CF_4(g)$ based on the tentative value of $\Delta_f H°(298.15\ K) = -223 \pm 1$ kcal mol^{-1} for $CF_4(g)$. Greenberg (1) determined the enthalpy of reaction by fluorine bomb calorimetry. Data of Humphrey (2) obtained by oxygen bomb calorimetry yield a $\Delta_f H°$ which is over 2 kcal more negative; however, this difference is probably within the uncertainties due to use of large amounts of Ti as a kindling agent and to corrections for incomplete combustion. Decomposition pressure data obtained mass spectrometrically by Drowart (3) are in close agreement with the selected $\Delta_f H°$, but Knudsen weight loss data of Grieveson (4) and solubility-activity data of Kirkwood (5) yield values less negative by 2 and 3 kcal, respectively. The results are summarized below.

The data of Drowart (3) show a significant drift while those of Grieveson (4) do not, but the latter should be corrected for $C_2Si(g)$ and $CSi_2(g)$ which are present in amounts of about 4 and 3%, respectively, at 2000 K. Silicon carbide may have a small vaporization coefficient, since rates of free evaporation reported by Voronin (6) and Ghoshtagore (7) yield apparent pressures which are smaller by factors of 1/30 to 1/10000.

Source	Method	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Greenberg (1)	F_2 Calorimetry	A	298	-	-591.9		-	-17.1
Humphrey (2)	O_2Calorimetry	B	303	-	-292.0		-	-19.6
Drowart (3)	Mass Spec.	C	2149-2316	7	136.9±0.7	124.61	-5.6±0.3	-16.9(-17.6)*
Grieveson (4)	Knudsen Wt. Loss	C	1785-2004	10	122.9±0.7	122.66	-0.2±0.4	-15.0
Kirkwood (5)	Soly. in Pb	D	1693	1	-	25.66	-	-14.1

A) $SiC(\alpha) + 4F_2(g) \rightarrow SiF_4(g) + CF_4(g)$ C) $SiC(\alpha) \rightarrow C(graph) + Si(g)$

B) $SiC(\alpha) + 2O_2(g) \rightarrow SiO_2(low\text{-}quartz) + CO_2(g)$ D) $SiC(\alpha) \rightarrow C(graph) + Si(\ell)$

*Value in parentheses is based on authors' data for $Si(\ell) \rightarrow Si(g)$ rather than JANAF value.

Heat Capacity and Entropy

Low temperature heat capacities are from data (54-296 K) of Humphrey (2) and are in good agreement with earlier data (54-295 K) of Kelley (8). The entropy is obtained from $C_p°$ using $S°(50\ K) = 0.038$ cal K^{-1} mol^{-1}. $C_p°$ above room temperature is based on enthalpy data of Humphrey (2) [389-1789 K], Walker (9) [373-1073 K] and Magnus (10) [372-1172 K]. Maximum deviations of the data from the selected values are 1.4, 2 and -1.7%, respectively; these occur in the range 370-621 K. Kirillin (11) obtained enthalpy data (1114-2843 K) for SiC mixed with 12% free carbon. When corrected for free carbon but not for 0.73% iron impurity, these data deviate by -1±1.5% from the selected values. Enthalpies (793-1790 K) of Fieldhouse (12) are high by 1-8% while those of Maksimenko (13) were not available for analysis.

Transition Data

SiC(α), also called hexagonal II or 6H, is one of the more common of many hexagonal forms which arise from various possible stacking sequences of the hexagonal SiC layers (14). The properties of these phases are so similar that they have not been adequately differentiated thermodynamically. It has frequently been assumed that cubic SiC(β) transforms to alpha at about 2300 K, but this seems unlikely since both phases have been prepared over temperature ranges of 1700-3000 K (14). Heat of formation and equilibrium data indicate that alpha is less stable up to 2000 K. The adopted functions suggest that this is the case at all temperatures; however, the stability difference is small.

Decomposition Data

The decomposition temperature, T_{dcm} = ~ 3245 K, is calculated as the value at which the total pressure reaches one atm for vapor consisting of C_2Si(44.3 mol %), Si(32.0%), CSi_2(21.2%), Si_2(1.9%), CSi(0.27%), and Si_3(0.25%). The tables predict decomposition to graphite and pure liquid silicon at about 3280 K; however, Scace (15) observed peritectic decomposition to graphite and solution containing 19 atom percent of carbon at 3103±40 K. In contrast, Dolloff (16) reported the peritectic at 2813±40 K and 27 percent carbon. Badami (17) has shown that decomposition in vacuum at lower temperatures (2400 K) leads to graphite.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

SILICON CARBIDE, BETA (SiC) CRYSTAL M_r = 40.0965

$S°(298.15\ K) = 16.610 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -72.221 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -73.220 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from $\Delta_r H°(298.15\ K) = -591.5\ kcal\ mol^{-1}$ for $SiC(\beta)+4F_2(g)+SiF_4(g)+CF_4(g)$, based on the tentative value of $\Delta_f H°(CF_4, g, 298.15\ K) = -223\pm1\ kcal\ mol^{-1}$. Greenberg (1) determined the enthalpy of reaction by fluorine bomb calorimetry. Data of Humphrey (2) obtained by oxygen bomb calorimetry yield a $\Delta_f H°$ which is over 3 kcal more negative; however, this difference is probably within the uncertainties due to use of large amounts of Ti as a kindling agent and to corrections for incomplete combustion. Decomposition pressure data obtained with the Knudsen weight loss method by Davis (3) are in good agreement with the selected $\Delta_f H°$, but similar data of Grieveson (4) and solubility-activity data of Rein (5) and d'Entremont (6) yield values less negative by 1.6 to 2.5 kcal. The results ar summarized below. Other equilibrium data (5) relating SiC and SiO_2 are not included, pending the revision of tables for SiO_2.

The data of Davis show a serious drift, while those of Grieveson do not; but the latter should be corrrected for $C_2Si(g)$ *and* $CSi_2(g)$ *which are present in amounts of about 4 and 3%, respectively, at 2000 K. Silicon carbide may have a small* vaporization coefficient, since rates of free evaporation reported by Voronin (7) and Ghoshtagore (8) yield apparent pressures which are smaller by factors of 1/30 to 1/10000.

A) $SiC(\beta) + 4F_2(g) \rightarrow SiF_4(g) + CF_4(g)$
B) $SiC(\beta) + 2O_2(g) \rightarrow SiO_2(\text{low quartz}) + CO_2(g)$
C) $SiC(\beta) \rightarrow C(\text{graph}) + Si(g)$
D) $SiC(\beta) \rightarrow C(\text{graph}) + Si(\ell)$

*Value in parentheses is based on author's data for $Si(\ell) \rightarrow Si(g)$ rather than JANAF value.

Heat Capacity and Entropy

Low temperature heat capacities are from data (54-296 K) of Humphrey (2). The entropy is obtained from $C_p°$ *using* $S°(50\ K) = 0.041\ cal\ K^{-1}\ mol^{-1}$. $C_p°$ above room temperature is based on Humphrey's enthalpy data (389-1693 K), which show a maximum deviation of ±1.2% from the selected functions. Humphrey's sample contained about 1% of α-SiC and about 0.6% of other impurities. Kirillin (9) obtained enthalpy data (1114-2843 K) for SiC mixed with 12% free carbon. When corrected for free carbon but not for 0.73% iron impurity, these data deviate by -1±2% from the selected values.

Transition Data

SiC(β), also called cubic or 3C, has a structure of the diamond or zinc blend type (10). The cubic phase differs from the many hexagonal forms only in the order of the stacking sequence of the hexagonal SiC layers. It has frequently been assumed that β transforms into α at about 2300 K, but this seems unlikely, since both phases have been prepared over temperature ranges of 1700-3000 K (10). Heat of formation and equilibrium data indicate that β is more stable up to 2000 K. The adopted functions suggest that this is the case at all temperatures; however, the stability difference is small.

Decomposition Data

The decomposition temperature, T_{dcm} = ~ 3259 K, is calculated as the value at which the total pressure reaches one atm for vapor consisting of C_2Si(45.4 mol %), Si(32.1%), CSi_2(20.1%), Si_2(1.8%), CSi(0.28%) and Si_3(0.23%). The tables predict decomposition to graphite and pure liquid silicon at about 3337 K; however, Scace (11) observed peritectic decomposition to graphite and solution containing 19 atom percent of carbon at 3103±40 K. In contrast, Dolloff (12) reported the peritectic at 2813±40 K and 27 percent carbon.

Enthalpy of Formation

Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibrium over the systems SiC-graphite (1) and boron-silicon-graphite (2). 3rd law analysis of the partial pressures of Si and SiC yields the results summarized below. The adopted value, $\Delta_f H°(298.15\ K) = 172 \pm 8$ is the mean of the two results and the uncertainty reflects the possible effect of an error of up to 4 cal K^{-1} mol^{-1} in the functions. The corresponding dissociation energy is $D^o_o = 106.5 \pm 8$ kcal mol^{-1}.

*Reaction: (A) C(graphite) + Si(g) = SiC(g)

Heat Capacity and Entropy

The ground state is assumed to be $^1\Sigma$, as suggested by Weltner and McLeod (3). By analogy with C_2, there should be a low-lying $^3\Pi$ excited state; this would dominate the thermodynamic functions at temperatures above 2000 K if the level lies below 5000 cm^{-1}. The $^3\Pi$ level is assumed to lie at 1000 cm^{-1}, intermediate between the value (4) observed for C_2 and that estimated for Si_2 (see JANAF table). Additional excited states, $^3\Sigma$, $^1\Pi$, $^1\Delta$ and $^1\Sigma$, are estimated by comparison with those observed or predicted (5) for C_2. The estimates for the electronic levels are relatively uncertain and probably yield an upper limit for the entropy at temperatures where SiC(g) is significant. A probable lower limit for the electronic contribution may be obtained by increasing the $^3\Pi$ level to 7000 cm^{-1} and omitting the other excited states. This would reduce the entropy by 3.5 and 2.0 cal K^{-1} mol^{-1} at 2000 and 4000 K.

The vibrational frequency is that estimated by Weltner (3) from a valence bond calculation using $k = 7.44 \times 10^5$ dyn/cm obtained from C_2Si. The constants $\omega_e x_e$, α_e, and r_e are estimated by interpolation between those (4, 6) for the $^3\Pi_u$ states of Si_2 and C_2. Use of constants based on the $^3\Pi$ state is consistent with the assumption that this state dominates the electronic partition function at high temperatures. B_e is calculated from r_e.

Ground State Quantum Weight: $1\ \sigma = [2]$
Point Group: $[D_{\infty h}]$
Bond Distance: C-Si = [1.75] Å
Bond Angle: C-Si-Si = [180]°
Rotational Constant: B_0 = [0.097996] cm^{-1}

Enthalpy of Formation

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the SiC-graphite (1), SiC-silicon (2) and boron-carbon-silicon (3) systems. 3rd law analysis of the aprtial pressures of CSi_2 and Si yields the concordant values 127.4, 127.9 and 128.6 kcal mol^{-1}. Two of the drifts are rather large, but they are opposite in sign so that no consistent entropy difference is apparent between the data and the tabulated functions. The drifts may be related to the low condensation coefficient for CSi_2 suggested by Drowart (2). Rates of free evaporation reported by Voronin (4) yield apparent pressures which are lower by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of $\Delta_f H°(298.15\ K)$ = 128±6 kcal mol^{-1} (535.552 ± 25 k J mol^{-1} includes allowance for an error in the entropy of up to 3 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

Weltner and McLeod (5) observed a band system in absorption at 5300 Å in matrix isolation and assigned this tentatively to the transition $^1\Pi_u \leftarrow X^1\Sigma_g^+$ of CSi_2. This assignment is adopted, although the evidence is not at all conclusive. A $^3\Pi_u$ excited state is assumed to lie at 12000 cm^{-1}, presumably arising from the same molecular orbital configuration as the $^1\Pi_u$ state. A linear, symmetric structure is assumed, as suggested by Weltner. The bond distance is estimated by comparison with Si_2, C_2 and C_3. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 7.46 \times 10$ (5) and $k\delta/l^2 = 0.11 \times 10^5$ dyn/cm. The stretching force constant is taken from C_2Si (5), while the bending force constant is from C_2Si and the $^1\Pi_u$ excited state of C_3 (5).

PREVIOUS: March 1967 (1 atm) CURRENT: March 1967 (1 bar)

TANTALUM CARBIDE (TaC) CRYSTAL M_r = 192.9589

$S°(298.15\ K) = 42.373 \pm 0.84\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 4273 \pm 200\ K$

$\Delta_f H°(0\ K) = -143.9 \pm 3.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -144.1 \pm 3.8\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [104.6 \pm 20.9]\ kJ\ mol^{-1}$

Enthalpy of Formation

There are eight oxygen bomb calorimetric studies on TaC reported in the literature (1-8) and one CO(g) equilibrium study (9). The adopted $\Delta_f H°(298.15\ K)$ value is derived from the calorimetric study of Huber et al. (6). These authors studied the combustion of ten TaC_x samples where x covers the range 0.724 to 0.998. For each composition seven or eight combustions were performed. Huber et al. (6) reported that the combustions varied from 94.83% to 100% completion but were usually greater than 99%. Corrections of the order 0.4% or less were made to the heat of combustion value to account for impurities. The calculated heats of formation for the ten compositions were fitted to both a quadratic and linear equation by the least squares method by Huber et al. (6). Each value was weighted inversely proportional to the square of its uncertainty. Using the linear equation for $\Delta_f H°(298.15\ K)$ and correcting for the JANAF value of $\Delta_f H°(Ta_2O_5, cr, 298.15\ K)$ (10), we extrapolate to x = 1.0, calculate, and adopt $\Delta_f H°(298.15\ K) = -34.44 \pm 0.9\ kcal\ mol^{-1}$ for TaC. The quadratic equation leads to a value of $-33.94 \pm 1.2\ kcal\ mol^{-1}$ which is consistent with our adopted value.

Huber et al. (6) and Storms (11) have reanalyzed the calorimetric and equilibrium data (1-9) for TaC_x (x=0.724 to 0.998). A graphical comparison of the results (i.e., $\Delta_f H°(298.15\ K)$ values vs. x) indicated that the linear or quadratic equation suggested by Huber et al. (6) is a satisfactory representation of all the $\Delta_f H°(298.15\ K)$ results for TaC_x. The shortcomings of the various studies have been discussed by Huber et al. (6) and Storms (11). *For comparison, the oxygen combustion study by* Mah (8) led to a reported value of $\Delta_f H°(298.15\ K) = -35.4 \pm 0.5\ kcal\ mol^{-1}$ for $TaC_{0.996}$ based on six combustions.

Heat Capacity and Entropy

Kelley (12) measured the heat capacity of TaC in the region 54-294 K (32 points). The reported data refer to stoichiometric TaC with corrections for 0.03% free carbon having been made by Kelley (12, 13). The sample contained less than 0.02% impurities other than free carbon. *Using the Debye function suggested by Kelley (12), we calculate and adopt* $S°(50\ K) = 0.831\ cal\ K^{-1}\ mol^{-1}$ and $H°(50;0) = 30.10\ cal\ mol^{-1}$.

Of the numerous enthalpy and heat capacity studies on TaC (14-24), the adopted $C_p°$ values for T > 298 K are derived primarily from the studies of Pankratz et al. (21), Chang (23), Levinson (17), *and Bolgar et al. (22). The heat capacity data* for 200 ≤ T ≤ 298 K are used to derive enthalpy values which in turn are used to constrain the high temperature enthalpy data. A polynomial curve fitting technique is used for the Pankratz et al. (21) and Levinson (17) data, with the above mentioned constraints, to obtain a smooth joining of the results near 298 K and to provide an equation suitable for extrapolation to T_{fus}. Pankratz et al. (21) determined the enthalpy of $TaC_{1.008}$ in the region 405-1700 K (14 data points) while Levinson (17) studied $TaC_{1.007}$ in the range 1289-2778 K (15 data points). Both sets of data are corrected to the stoichiometric composition (TaC) assuming excess free carbon. These corrections are roughly 20 cal mol^{-1} at 1000 K and 90 cal mol^{-1} at 2500 K (10). Chang (23) determined the enthalpy of a reported stoichiometric TaC sample for 324-985 K (11 data points). Bolgar et al. (22) reported an equation for $C_p°$ values as a function of T and x for the 1200-2400 K range. This equation was based on a study of four TaC_x compositions. We use this equation to extrapolate to the TaC composition.

The adopted tabulation yields enthalpy values for T < 1200 K which are very similar to those suggested by Pankratz et al. (21), the difference being no more than ±20 cal mol^{-1}. Above 1200 K, the data of Pankratz et al. (21) lies low approaching roughly 1% in the 1700-1800 K region. The Chang data (23) lies below the tabulated enthalpy values for T < 600 K. The average deviation is 0.94% with the maximum of -2.5% occurring at 324.4 K. The Levinson data (17) has an average deviation of 0.5% with considerable scatter. The $C_p°$ values of Bolgar et al. (24) has considerable scatter and deviates from our tabulated values by an average deviation of 6%.

Phase Data

See the liquid table for details.

Fusion Data

See the liquid table for details.

PREVIOUS: CURRENT: December 1973

TANTALUM CARBIDE (TaC) LIQUID M_r = 192.9589

$S°(298.15\ K) = [68.279]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 4273 \pm 200\ K$

$\Delta_f H°(298.15\ K) = [-33.955]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [104.6 \pm 20.9]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of TaC(ℓ) at 298.15 K is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(4273 K) - H°(298.15 K), between TaC(cr) and TaC(ℓ).

Heat Capacity and Entropy

The heat capacity for TaC(ℓ) is assumed to be 16.0 cal K^{-1} mol^{-1} for the entire liquid phase. A glass transition is assumed at 2800 K, below which the heat capacity values of the crystal are used. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Phase Data

TaC has a cubic structure of the NaCl type (11) and has a wide homogeneity range. From the phase diagram for the Ta-C system given by Storms (11), the temperature dependent homogeneity range extends from x=0.58 at 3603±100 K to x=0.998 or possibly x=1.00. The phase boundary at a eutectic temperature of 3673±50 K is $TaC_{0.98}$. A discussion of the phase diagram for TaC_x (x=0.00 to 1.6) is given by Storms (11).

Fusion Data

The phase diagram given by Storms (1) indicated a eutectic melting at 3673±50 K. A congruent melting point was estimated by Storms (1) at roughly 4273 K for $TaC_{0.88}$. As an approximation due to the uncertainties in this area of the phase diagram, we adopt T_{fus} = 4273±200 K and assign this melting point to TaC. We assume a heat of melting $\Delta_{fus}H°$ = 25.0±5.0 kcal mol^{-1} ($\Delta_{fus}S°$ = 5.85 cal K^{-1} mol^{-1}).

Decomposition Data

Using JANAF auxiliary data (2), we calculate T_{dcm} = ~ 5580 K, as that temperature at which $\Delta_r G°$ is zero for the reaction TaC(ℓ) = Ta(ℓ) + C(g).

PREVIOUS: CURRENT: December 1973

$S°(298.15\ K) = 24.229 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3290 \pm 15\ K$

$\Delta_f H°(0\ K) = -182.8 \pm 4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -184.1 \pm 4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [71.128]\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -44.0\ kcal\ mol^{-1}$ ($-184.096\ kJ\ mol^{-1}$) is derived from $\Delta_r H°(298.15\ K) = -275.72\ kcal\ mol^{-1}$ for reaction (a) determined by Humphrey (1) who burned TiC(cr) in an oxygen bomb calorimeter. The author reported that the combustion product TiO_2 was >95 per cent rutile and <5 per cent anatase, the heat of formation is calculated assuming the above distribution. The uncertainty adopted is due mainly to the uncertainty in TiO_2(rutile).

Using atomic absorbtion spectroscopy Vidale (2) determined that the pressure ($\log P_{Ti} = -7.269$) of Ti(g) at 1666 K was equal to the pressure of TiC(cr) at 2220 K. Using this data for reaction (b) we obtain a $\Delta_f H°(298.15\ K) = -43.02\ kcal\ mol^{-1}$. Lowell and Williams (3) measured the $\Delta_f H°(2028\ K) = -43.3 \pm 4\ kcal\ mol^{-1}$ of TiC(cr) directly using a high temperature calorimeter, which reduces to $\Delta_f H°(298.15\ K) = -37.7 \pm 4\ kcal\ mol^{-1}$.

Fujishiro and Gokcen (4) determined the equilibrium pressure of Ti(g) in reaction (d) in the temperature range 2383-2593 K. 3rd law analysis of the data yields a $\Delta_f H°(298.15\ K) = -31.6\ kcal\ mol^{-1}$. Brantley and Beckman (5) measured equilibirum pressures of CO for reaction (e) in the temperature range 1278 - 1428 K. 3rd law analysis of the data yields a $\Delta_f H°(298.15\ K) = -61.9\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

Low temperature heat capacities (55 - 295 K) have been taken from Kelley (6). Naylor (7) measured heat contents from 360 to 1738 K and Levinson (8) from 1274 to 2799 K. High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 2799 K the heat capacity is graphically extrapolated. The entropy is based on $S°(50;0) = 0.065\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

See the liquid table for details.

TITANIUM CARBIDE (TiC) LIQUID M_r = 59.891

$S°(298.15\ K) = [47.401]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3290 \pm 15\ K$

$\Delta_f H°(298.15\ K) = [-108.334]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [71.128]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from $\Delta_f H°$(cr, 298.15 K) by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(3290 K) - H°(198.15 K), between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200 K below which the heat capacity is obtained from that of the crystal; above 2200 K it is assumed constant and estimated as 15 cal K^{-1} mol^{-1}. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The adopted T_{fus} *is taken from* the phase diagram of the system Ti-C, at the composition 50% Ti and 50% C, reported by Rudy and Harmon (1). Earlier reports by Friederich and Sittig (2) and Moers (3) gave a T_{fus} of 3430±100 K and 3410±90 K, respectively. $\Delta_{fus} H°$ *is derived from an estimated* $\Delta_{fus} S°$ = 2.5 cal K^{-1} g-atom^{-1}, as suggested by Kubaschewski et al (3).

PREVIOUS: CURRENT: June 1968

$S°(298.15\ K) = 33.321\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3805 \pm 125\ K$

$\Delta_f H°(0\ K) = -196.0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -196.6 \pm 13\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [79.496]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K) = -47.16 \pm 1.5\ kcal\ mol^{-1}$ was calculated from the standard Gibbs energy of formation of $-38.9 \pm 1.5\ kcal\ mol^{-1}$ at 2675 K reported by Pollock (1). Using spectrophotometric data reported by Vidale (2), we calculated $\Delta_f H°(298.15\ K) = -46.9 \pm 1\ kcal\ mol^{-1}$. These values were averaged with $\Delta_f H°(298.15\ K) = 47.0 \pm 0.6\ kcal\ mol^{-1}$ reported by Mah (3). The equilibria data reported by Prescott (4) and Kutsev (5) were considered but not used.

Heat Capacity and Entropy

Enthalpy data over the range 470.8 to 1,174.4 K were taken from a preliminary report by Mezaki et al. (6). These data were smoothed by means of the Shomate plot into low temperature data reported by Westrum and Feick (7). High temperature data reported by Neel et al. (8) and McDonald et al. (9) were then used to obtain the heat capacity above 1174 K.

Fusion Data

Melting points were measured by Agte and Alterthum (10) and Fredrich and Sittig (12). The value of 3805±125 K by Agte and Alterthum was chosen. Frederich and Sittig (11) obtained a measurement of 3300 K but estimated 3500 K because of the clouding formation of ZrO_2. Worrell (12) quoted a value of 3480°C taken from Storms (13). The enthalpy of melting is derived from an estimated $\Delta_{fus} S° = 2.5\ cal\ K^{-1}\ g\text{-}atom^{-1}$.

PREVIOUS: June 1964 CURRENT: December 1964

ZIRCONIUM CARBIDE (ZrC) LIQUID M_r = 103.231

$S°(298.15\ K)$ = [53.577] J K^{-1} mol^{-1}

T_{fus} = 3805 ± 125 K

$\Delta_f H°(298.15\ K)$ = [-118.877] kJ mol^{-1}

$\Delta_{fus} H°$ = [79.496] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(ZrC, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(ZrC, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(3805\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

$C_p°(\ell)$ at and below 2500 K is assumed to be equal to that of ZrC(cr). Above 2500 K the heat capacity is estimated to be constant. $S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Enthalpy of Formation

Messerle and Krauss (1) have reported the dissociation energy as 49300 ± 300 cm^{-1} from the variation of the rotational structure cut-off with vibrational level in the $c\,^1\Pi_g$ state. This state dissociates into $C(^3P) + C^3(P)$, due to an avoided crossing (2), these dissociation products are those of the ground state. The uncertainty in the determination is generous and thus we adopt $D_0^0 = 140.95 \pm 0.9$ kcal or $\Delta_f H°(C_2, g, 0\ K) = 198.2 \pm 0.9$ kcal mol^{-1}, using $\Delta_f H°(C, g, 0\ K) = 169.576$ kcal mol^{-1} (3).

Brewer et al. (4) have reviewed several other earlier determinations which confirm $\Delta_f H°(0\ K) = 195 \pm 5$ kcal mol^{-1}. The extensive mass spectrometric data of Drowart et al. (5) yield a 3rd law $\Delta_f H°(0\ K) = 199.2 \pm 1.4$ kcal mol^{-1} in excellent agreement with the adopted value.

Heat Capacity and Entropy

The observed molecular constants and electronic levels were taken from Ballik and Ramsay (2). The estimated parameters are from the correlation calculations of Fougere and Nesbet (6) and Clementi (7), the electronic levels are T_o values. Not all predicted states were included since the contribution of levels above 40000 cm^{-1} is neligible. The functions were calculated from the partition function $Q = Q_t \Sigma Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$, the values for Q_r^i and Q_v^i were calculated with first order anharmonic corrections. The functions are similar to those reported by Altman (8) and Clementi (7) but include several additional states.

Enthalpy of Formation

The electron affinity of C_2 has been obtained by Honig (1) as 4 ± 0.8 eV from the difference in enthalpies of sublimation of neutral C_2 and C_2^- and the work function of graphite. Thus, we have the reaction

$$C_2(g) + e^- \rightarrow C_2^-(g) \qquad \Delta H(0\ K) = -92.2 \pm 20\ kcal.$$

Using $\Delta_f H°(C_2, g, 0\ K) = 198.2\ kcal\ mol^{-1}$ (2), we obtain $\Delta_f H°(C_2^-, g, 0\ K) = 106 \pm 20\ kcal\ mol^{-1}$, which is adopted.

A value for the enthalpy of formation may be obtained from a linear Birge-Sponer extrapolation of the ground state vibrational levels, which gives 195.8 kcal for the reaction.

$$C_2^-(g) \rightarrow C(g) + C^-(g).$$

With auxiliary data (2) this yields $\Delta_f H°(C_2^-, g, 0\ K) = 114.5\ kcal\ mol^{-1}$, in good agreement with the adopted value.

Heat Capacity and Entropy

The molecular constants and electronic levels are from Herzberg and Lagerqvist (3). The values are not definitely ascribed to C_2^- by Herzberg and Lagerqvist, but there is a good deal of evidence to support this assignment. Recently Milligan and Jacox (4) have shown that matrix isolated bands previously attributed to $C_2(g)$ are enhanced in the presence of a photoelectron source. The matrix spectra correspond to the gas system reported by Harzberg and Lagerqvist (3) and leave little doubt that the species is C_2^-.

The estimated electronic level is assumed to be a $^2\Pi$ state and is obtained from the isoelectronic CN(g) (2).

BERYLLIUM CARBIDE (BeC_2) IDEAL GAS M_r = 33.03418

$S°(298.15\ K)$ = [218.643] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [558.678] kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [564.840] kJ mol^{-1}

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[1580](1)
[423](2)
[1947](1)

Ground State Quantum Weight: 1 σ = 1
Point Group: [$C_{\infty v}$]
Bond Distances: Be-C = [1.407] Å C≡C = [1.2] Å
Bond Angle: Be-C-C = [180]°
Rotational Constant: B_0 = [0.481016] cm^{-1}

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was estimated as a lower positive limit by U. S. Nat. Bur. Stand (1).

Heat Capacity and Entropy

The vibrational frequencies, bond angle, and configuration were estimated by Chupka, et al (2). Bond distances were calculated assuming the C-C bond distance was the same as in acetylene.

Bond Angle: Cl-C-C = 180°
Rotational Constant: B_0 = 0.046368 cm^{-1}

Enthalpy of Formation

The enthalpy of formation of dichloroacetylene is calculated from the estimated $\Delta_r H°(298.15\ K) = -53 \pm 10$ kcal mol^{-1} for $ClC{\equiv}CCl(g) + Cl_2(g) \rightarrow Cl_2C{=}CCl_2(g)$, using $\Delta_f H°(C_2Cl_4, g, 298.15\ K) = -2.9$ kcal mol^{-1} (1). The value of $\Delta_r H°(298.15\ K)$ is assumed to be the same as that for the reaction $HC{\equiv}CH(g) + Cl_2(g) \rightarrow CHCl{=}CHCl(g)$, using $\Delta_f H°(CHCl{=}CHCl, g, 298.15\ K) = 1.2$ kcal mol^{-1} (2).

Heat Capacity and Entropy

The linear molecular structure and bond distances were determined from electron diffraction studies by Hassel and Viervoll (3).

All five fundamental vibrational frequencies are calculated by the modified valence force method (4) from estimated force constants which are interpolated from those of C_2I_2 (5), CH≡CF (6), CH≡CCl (6), CH≡CBr (6), and C_2D_2 (4).

Point Group: D_{2h} $\sigma = 4$
Bond Distances: Cl-C = 1.724 Å C-C = 1.327 Å
Bond Angle: Cl-C-Cl = 113.3°
Product of the Moments of Inertia: $I_A I_B I_C = 3.431926 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of combustion $\Delta E(Cl_2Cl_4, \ell, 293\ K)$ has been determined by the "Quartz Wool" method by Smith et al. (1). The free chlorine produced from combustion was reduced to hydrogen chloride by a quartz spiral moistened with a solution of arsenious acid in the combustion bomb. Based on the reported results, the enthalpy change at 298.15 K for the reaction $C_2Cl_4(\ell) + O_2(g) + 2H_2O(\ell) = 2CO_2(g) + 4HCl(aq, 600H_2O)$ is evaluated as -198.40 kcal mol^{-1}, using recent auxiliary data from (2) and Parker (3) and $C_p°$ for $C_2Cl_4(\ell)$ from Kurbatov [4]. Employing $\Delta_f H°(298.15\ K)$ = -94.054, -39.823 and -68.315 kcal mol^{-1} for $CO_2(g)$, $HCl(aq, 600H_2O)$ and $H_2O(\ell)$, respectively, we calculate the enthalpy of formation for $C_2Cl_4(\ell)$ as -12.367 kcal mol^{-1}. Incorporating this value with the value $\Delta_{vap}H°(298.15\ K) = 9.4$ kcal mol^{-1} obtained from Eftring (5), we derive $\Delta_f H°(298.15\ K) = -2.97 \pm 0.7$ kcal mol^{-1} for $C_2Cl_4(g)$.

Heat Capacity and Entropy

The molecular structure of $C_2Cl_4(g)$ was investigated by the sector-visual method of electron diffraction by Ramachandra and Livingston (6). The reported bond distances and angle are in agreement with those measured by Karle and Karle (7), using the sector-microphotometer method, and Lipscomb (8). The molecular structure has also been determined by Brockway et al. (9) Laszlo (10), and Dornte (11) by use of electron diffraction. The values reported by Ramachandra and Livingston (6), are adopted.

The vibrational spectra of tetrachloroethylene have been studied by numerous investigators. The vibrational frequencies assigned by Mann et al. (12), are adopted here. These authors also reviewed the results of earlier investigations in detail.

The electronic levels and quantum weights are obtained from Herzberg (13).

The principal moments of inertia are: $I_A = 48.8379 \times 10^{-39}$, $I_B = 62.8935 \times 10^{-39}$ and $I_C = 111.7314 \times 10^{-39}$ g cm^2.

Point Group: D_{3d}

Bond Distances: Cl-C = 1.74 Å C-C = 1.55 Å σ = 6

Bond Angles: Cl-C-Cl = 110° Cl-C-C = 109°

Product of the Moments of Inertia: $I_A I_B I_C = 9.144710 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

Smith et al. (1) determined the heat of combustion of C_2Cl_6(cr) to be $\Delta E(293\ K) = -718.7 \pm 2$ cal/g (uncorrected) by use of the 'Quartz Wool' method. The free chlorine produced was reduced to HCl by employing the quartz spiral moistened iwth a solution of arsenious acid in the combustion bomb. Adopting the reported results and recent auxiliary data (2, 3, 4), we evaluate the values $\Delta_c H°(298.15\ K) = -173.525$ and $\Delta_f H°(298.15\ K) = -48.58$ kcal mol^{-1} for C_2Cl_6(cr). Kirkbride (5) measured the enthalpy changes as -32.0 and 4.7 kcal mol^{-1} for the following two reactions by solution calorimetry: $C_2Cl_4(\ell)+Cl_2(g) = C_2Cl_6(aq)$ and $C_2Cl_6(cr) = C_2Cl_6(aq)$. Hence we obtain $\Delta_f H°(298.15\ K) = -49.07$ kcal mol^{-1} for C_2Cl_6(cr), using $\Delta_f H°(C_2Cl_4, \ell, 298.15\ K) = -12.37$ kcal mol^{-1}. This value is in reasonable agreement with the adopted value -48.58 kcal mol^{-1}.

Hexachloroethane (cr) has three modifications, namely triclinic, monoclinic and cubic, with transition temperatures of 318 and 345 K (4). The sublimiation pressures over the different phases have been measured by Ivin (8), Lee (7), and Nitta (26). Based oin these data, values for $\Delta_{sub}H°$(triclinic, 298.15 K) are derived by a modified second and third law mthod to be 16.5, 17.1 and 14.8 kcal mol^{-1}, respectively. The analysis depends on the $C_p°$ and $\Delta_{trs}H°$ data determined by (4). The order of magnitude of the two $\Delta_{trs}H°$ values is confirmed by R. A. McDonald, private communication, Thermal Research Laboratory, The Dow Chemical Company, Midland, Michigan. Pressures reported by Nelson (6) are systematically lower than the above data by about 10 per cent; therefore, his data are not used. Third law analysis is not applicable to the pressure data due to lack of S°(triclinic, 298.15 K). Adopting $\Delta_{sub}H°(298.15\ K) = 16.5$ and $\Delta_f H°(298.15\ K) = -48.58$ kcal mol^{-1} for C_2Cl_6 (triclinic), we obtain $\Delta_f H°(298.15\ K) = -32.08$ kcal mol^{-1} for C_2Cl_6(g).

The equilibrium constant at 776 K for the reaction $C_2Cl_6(g) = C_2Cl_4(g) + Cl_2(g)$ was reported as 0.8±0.1 (atm) by Puyo et al. (9). The corresponding enthalpy change at 298.15 K is evaluated to be 30.8 kcal mol^{-1} by the third law method, yielding $\Delta_f H°(C_2Cl_6, g, 298.15\ K) = -33.77$ kcal mol^{-1} which is in fair agreement with the adopted one.

Heat Capacity and Entropy

The molecular structure of C_2Cl_6 has been studied previously by means of infrared and Raman spectroscopy (10), X-ray (11), and electron diffraction (12-18). The molecule was found to be in the staggered position in the vapor and solid states. The bond distances and angles adopted here are those reported by Swick et al. (16).

Incomplete assignments of vibrational frequencies for C_2Cl_6(g) were reported by many investigators (21-24). The adopted frequencies, except the torsional mode ν_4, are obtained from Carney et al. (19). The torsional mode is treated as a hindered internal rotation, and thermodynamic properties are calculated (25) from the barrier height of V_0 = 12.8 kcal mol^{-1} which was evaluated by Karle (20) from electron diffraction data. The value of S°(298.15 K) is calculated based on S°(400 K) = 105.355 cal K^{-1} mol^{-1} which is derived from the free rotor value S°(400 K) = 108.121 cal K^{-1} mol^{-1} by subtraction of the entropy difference between a free rotor and hindered rotor at 400 K. Internal rotation contributions to $C_p°$ at temperatures below 350 K could not be calculated since they are beyond the range of the values above 350 K and the corresponding harmonic oscillator values (ν_4 = 67 cm^{-1}) below 150 K. This calculation presumes that the internal rotation approaches harmonic oscillation as V/RT >>1.

The principal moments of inertia are: $I_A = 79.9217 \times 10^{-39}$, $I_B = 92.8302 \times 10^{-39}$ and $I_C = 123.2582 \times 10^{-39}$ g cm^2.

$S°(298.15\ K) = 85.434 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -86.21 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -85.35 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

Mah (1) determined the enthalpy of combustion of Cr_3C_2(cr) using oxygen bomb calorimetry. She reported $\Delta_c H°(298.15\ K)$ = -574.5±0.4 kcal mol^{-1} based on the reaction $Cr_3C_2(cr) + 17/4\ O_2(g) = 3/2\ Cr_2O_3(cr) + 2\ CO_2(g)$. Using auxiliary JANAF data (2), we calculate $\Delta_f H°(298.15\ K)$ = -20.4 kcal mol^{-1} for Cr_3C_2(cr). Mah [1] reported that of the *six combustion runs four were* complete combustions whereas the other two were 99.17% and 98.57% complete. Corrections were made by Mah (1) for incomplete combustion, formation of small amounts of CO(g), and impurities. These corrections amount to less than 1.95% of the $\Delta_c E°_v$

There are many equilibrium studies involving Cr_3C_2(cr) (3-13). Our analysis of a portion of these studies is tabulated Reference

Reactions: (A) $3\ Cr_2O_3(cr) + 13\ C(cr) = 2\ Cr_3C_2(cr) + 9\ CO(g)$. (B) $3\ Cr(cr) + 2\ C(cr) = Cr_3C_2(cr)$.
**1374 K point rejected due to statistical test.

The CO(g) equilibrium pressures measured by Heusler (3) in the range 1159-1369 K are higher than those of Kelley et al. (4) by a factor varying from 2.0 to 1.4 with increasing temperature. Three studies measured the chromium pressure in equilibrium with C(cr) and Cr_3C_2(cr) (5, 7, 9). Reported heats of formation for Cr_3C_2 from these studies are -23.1 kcal mol^{-1} (5), -14.2 kcal mol $^{-1}$ (7), and -22 kcal mol^{-1} (9). Alekseev and Shvartsman (6) studied the decarburization of the chromium carbides. Mah (1) analyzed their data and reported $\Delta_f H°(298.15\ K)$ = -16.6 kcal mol^{-1} for Cr_3C_2(cr).

The $\Delta_f H°$ results are quite scattered with the emf results being roughly 5 kcal mol^{-1} more positive than the combustion and pressure equilibrium studies. Possible explanations for these discrepancies are discussed by Kulkarni and Worrell (16). We adopt $\Delta_f H°(298.15\ K)$ = -20.4±3.0 kcal mol^{-1} (-85.354±12.6 kJ mol^{-1}) for Cr_3C_2(cr) based on the combustion study by Mah (1).

Heat Capacity and Entropy

The heat capacity of Cr_3C_2(cr) has been measured by Kelley et al. (4) [53-296 K, 29 pts.) and DeSorbo (14) (12-301 K, 65 pts.). As reported by DeSorbo (14), the results of these two studies differ by no more than 0.1%. Using the Debye function 3D (300/T) as suggested by DeSorbo (14), we calculate and adopt S°(12 K) = 0.0297 cal K^{-1} mol^{-1} and H°(12;0) = 0.268 cal mol^{-1}. The enthalpy has been measured by Kelley et al. (4) [481-1576 K, 17 pts.] and Oriani and Murphy (15) [297-1188 K, 11 pts.]. As stated by Oriani and Murphy (15), *their results are somewhat lower than those of Kelley et al. (4); the maximum* difference is 1.2% at 970 K. For T > 298.15 K, we base our adopted values on the enthalpy data of Kelley et al. (4). The enthalpy data is subjected to a curve fit procedure with the constraint that it join smoothly in the 298 K region with the enthalpy derived from the heat capacity data of Kelley et al. (4). The deviations between the tabulated and observed enthalpy average 0.26% with a maximum of 0.78% at the lowest observed temperature, 480.7 K.

Phase Data

Storms (17) has summarized the phase information for the Cr-Cr_3C_2 system and reported that Cr_3C_2 has an orthorhombic structure. The range of homogeneity is unknown (17).

Decomposition Data

The tentative phase diagram for the Cr-Cr_3C_2 system proposed by Storms (17) indicated that Cr_3C_2 has an incongruent melting point at 2168 K.

Enthalpy of Formation

Farber et al. (1), have obtained equilibrium-weight change data over the C-CF_4 system. Our reanalysis of these data assumes that the equilibrium constants for CF_4, CF_3 and CF_2 are those in the JANAF Tables, and that C_2F_2 was the only other C-F species present at equilibrium. This gives maximum possible concentrations of C_2F_2 and places a lower limit on the heat of formation. The $\Delta_f H°(C_2F_2, g, 298.15\ K)$ values so obtained range from +10 kcal mol^{-1} from data at 2023 K to -10 kcal mol^{-1} from data at 2373 K; we adopt a weighted mean of +5±5 kcal mol^{-1} (20.920 ± 21 kJ mol^{-1}). This value still predicts complete dimerization of CF at 1 atmosphere pressure below about 2200 K, but only CF would exist under experimental conditions such as the study by Farber.

Farber et al. (1) also investigated the mass spectrum of the vapor over the C-CF_4 system and did not detect any ion ascribable to C_2F_2. This is additional support for the value adopted.

The C-C bond dissociation energy in C_2F_2 is 113 kcal mol^{-1}, using JANAF CF(g) table (Dec. 31, 1967). This value is 115 kcal weaker than the bond dissociation energy of acetylene. In order to explain such a large decrease, a crossing of the repulsive approach of two $^2\Pi$ CF molecules with an attractive approach of two $^4\Sigma$ CF molecules may be postulated. This follows the reasoning used by Simons (2) to explain the bond dissociation energy of C_2F_4.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that for $C_2H_2(g)$. The C-F and C-C bond distances are estimated from those in HC ≡ CF reported by Tyler and Sheridan (3). The assymmetric stretching frequency, ν_3 = 1149 cm^{-1}, was observed by Heicklen and Knight (4). The other vibrational frequencies were estimated by comparison with those for $C_2H_2(g)$ and $C_2HF(g)$ reported by Herzberg (5), Hunt and Wilson (6), and Brown and Tyler (7).

521(1)	192(2)

Ground State Quantum Weight: [1] $\sigma = 3$

Point Group: C_{3v}

Bond Distances: C-F = 1.335 Å C-C = 1.461 Å CN = 1.153 Å

Bond Angles: F-C-F = 107.5° F-C-C = 111.38°

Product of the Moments of Inertia: $I_A I_B I_C = 1.186732 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the enthalpies of formation of CF_3, C_2F_4, and CF_3X(X = H, Cl, Br, I, CN). Details of the input data and adjustment are given in (1). Input included a calorimetric link to $NF_3(g)$ and $CF_4(g)$ plus an equilibrium link to $C_2F_6(g)$ and $C_2N_2(g)$. The calorimetric study (2) gave $\Delta_r H° = -824.4 \pm 0.6$ kcal mol^{-1} at 298.15 K for the reaction $3CF_3CN(g) + 5NF_3(g) + 6CF_4(g) + 4N_2(g)$. Equilibrium data (3) in the range 865-925 K give $\Delta_r H°$ (3rd law) = 10.59 and $\Delta_r H°$ (2nd law) = 10.59±0.20 kcal mol^{-1} at 298.15 K for the reaction $C_2F_6(g) + C_2N_2(g) + 2CF_3CN(g)$. The entropy difference, $\Delta_r S°$ (2nd law) - $\Delta_r S°$ (3rd law), is 0.0±1.5 cal $K^{-1}\ mol^{-1}$. Deviations between the selected $\Delta_f H°$ and the two observations are 1.37 and 0.15 kcal mol^{-1}, respectively, both considerably less than the overall uncertainties including those in auxiliary values of $\Delta_f H°$. Subsequent to the adjustment, Curnutt and Sinke (4) reported $\Delta_r H° = -197.6 \pm 0.9$ kcal mol^{-1} from a calorimetric study of $CF_3CN(g) + 1.25\ O_2(g) + 1.5\ H_2O(\ell) + 2\ CO_2(g) + 0.5\ N_2(g) + 3HF(aq, 120\ H_2O)$. Their *result of* $\Delta_f H° = -118.4 \pm 1.2$ kcal mol^{-1} *is confirmation of the selected value.*

Heat Capacity and Entropy

The *molecular structure has been derived from electron-diffraction data* by Danford and Livingston [5] and from microwave data by Sheridan and Gordy (6) and Thomas et al. (7). These studies are in substantial agreement except for a difference of about 0.04 Å in the C-C bond distance. We adopt the results of Thomas et al. (7) since they are based on data for several isotopic species. Principal moments of inertia are: $I_A = 14.6267 \times 10^{-39}$ and $I_B = I_C = 28.4842 \times 10^{-39}\ g\ cm^2$. Vibrational frequencies are taken from the assignments of Edgell and Potter (8). All values except ν_8 are from infrared spectra of the vapor phase. Raman spectra of the liquid provide ν_8 and confirm the infrared data. Similar assignments have been given by Janz and Wait (9) based on spectra of Wait and Janz (10).

Pace and Bobka (11) used low temperature calorimetric data to derive the entropy of the ideal gas at the normal boiling point of 205.47 K. The experimental value of 65.01±0.2 cal $K^{-1}\ mol^{-1}$ is in good agreement with 65.03 cal $K^{-1}\ mol^{-1}$ obtained from this table. The largest uncertainty in $C_p°$ and S° probably arises from neglect of anharmonicity and rotational distortion. Uncertainty in the entropy is estimated to vary from 0.1 to 0.5 cal $K^{-1}mol^{-1}$ over the range 300 to 1000 K. Discussions of the neglect of anharmonicity are given on the tables for $CClF_3(g)$ and $CF_4(g)$.

394(1)	406(1)	1186(1)
190(1)	508(1)	558(1)

Ground State Quantum Weight: 1 $\sigma = 4$
Point Group: D_{2h}
Bond Distances: C-F = 1.313 Å C-C = 1.313 Å
Bond Angle: F-C-F = 114°
Product of the Moments of Inertia: $I_A I_B I_C = 1.588028 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). In this case, the selected $\Delta_f H°$ corresponds to the weighted average of three calorimetric studies (2, 3) which may be reduced to the following:

Source	Reaction	$\Delta_r H°(298.15\ K)$ kcal mo^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(2)	$C_2F_4(g) + CF_4(g) + C(graphite)$	-65.4±0.5	-157.6±0.6
(2)	$C_2F_4(g) + 2H_2(g) + 4HF(50\ H_2O) + 2C(graphite)$	-150.9±1.2	-156.2±1.3
(3)	$C_2F_4(g) + 4Na(cr) + 4NaF(cr) + 2C(graphite)$	-392.9±1.3	-157.2±1.4

Amorphous carbon was formed in all three calorimetric reactions and separate combustions were made to refer the observed product to the standard state of graphite. Other calorimetric studies (4, 5, 6) are omitted because of apparent uncertainties in the reductions to the standard-state reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Karle (7), Broun (8) and Young (9). The resulting structures differ in minor respects, particularly in the exact location of the two carbons. Values from Karle (7) are adopted since they are intermediate between the others. Values from Young (9) and Broun (8) correspond to changes of ±2.2% in the product of the moments of inertia. Principal moments of inertia for the adopted structure are: $I_A = 15.3019 \times 10^{-39}$, $I_B = 25.4600 \times 10^{-39}$ and $I_C = 40.7619 \times 10^{-39}\ g\ cm^2$. Vibrational fundamentals are those selected by Shimanouchi (10) from the data of Mann (11), Monfils (12) and Nielsen (13).

Furukawa (14) reported low-temperature calorimetric data from which the ideal gas entropy may be derived as 64.54±0.09 cal $K^{-1}\ mol^{-1}$ at 197.53 K. The calculated entropy from this table is also 64.54 cal $K^{-1}\ mol^{-1}$. The range in values of $I_A I_B I_C$ corresponds to an entropy change of ±0.022 cal $K^{-1}\ mol^{-1}$.

PREVIOUS: June 1969 (1 atm) CURRENT: June 1969 (1 bar)

HEXAFLUOROETHANE (C_2F_6) IDEAL GAS M_r = 138.012418

$S°(298.15\ K) = 332.185 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -1335.6 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1343.9 \pm 5.0\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}	ν, cm^{-1}
1228(1)	1117(1)	376(2)
807(1)	714(1)	1251(2)
348(1)	1243(2)	523(2)
Torsion	619(2)	220(2)

Ground State Quantum Weight: 1 $\sigma = 6$
Point Group: D_{3d}
Bond Distance: C-F = 1.32 Å C-C = 1.56 Å
Bond Angle: C-C-F = 109.5 ± 1.5°
Product of the Moments of Inertia: $I_A I_B I_C = 6.005449 \times 10^{-113}\ g^3\ cm^6$
Reduced Moment of Inertia: $I_{red} = 7.32 \times 10^{-39}\ g\ cm^2$
Barrier to Internal Rotation: $V = 3.96\ kcal\ mol^{-1}$

Enthalpy of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Data pertinent to C_2F_6 are summarized below. Calorimetric data (7) for the reaction of C_2F_6 with potassium were omitted from the adjustment due to insufficient characterization of the products.

Source	Method	Reaction	$\Delta_r H°(298.15\ K)$ $kcal^{-1}mol^{-1}$	$\Delta_f H°(298.15\ K)$ $kcal^{-1}mol^{-1}$
(2)	Calorimetric	$3\ C_2F_6(g) + 2\ NF_3(g) + 6\ CF_4(g) + N_2(g)$	-311.6 ± 3.0	-321.3 ± 1.2
(3)	Calorimetric	$3\ CF_3CN(g) + 5\ NF_3(g) + 6\ CF_4(g) + 4\ N_2(g)$	-824.4 ± 0.6	---
(4)	Equilibrium	$2\ CF_3CN(g) + C_2F_6(g) + C_2N_2(g)$	-10.59± 0.5	-322.2 ± 1.8
(5)	Equilibrium	$C_2F_6(g) + Br_2(g) + 2\ CBrF_3(g)$	3.30± 0.7	-320.9 ± 1.6
(6, 5)	Kinetic	$C_2F_6(g) + 2\ CF_3(g)$	97.6 ± 6	-322.4 ± 6

Heat Capacity and Entropy

The adopted molecular structure was derived from electron-diffraction data by Swick and Karle (8). The vibrational frequencies are from the assignment of Carney et al. (9), who reviewed the extensive spectral data. Shimanouchi (10) has selected the same frequencies. Low-temperature calorimetric data were used by Pace and Aston (11) to derive a value for the entropy of the ideal gas of 69.88 ± 0.20 cal $K^{-1}\ mol^{-1}$ at 194.87 K. This value is used to fix the barrier to internal rotation at 3960 cal/mol. Thermodynamic functions are calculated from these parameters, using hindered internal rotation in place of a torsional vibration. Principal moments of inertia are: $I_A = 29.3165 \times 10^{-39}$, and $I_B = I_C = 45.2602 \times 10^{-39}\ g\ cm^2$.

An uncertainty of ±0.2 cal $K^{-1}\ mol^{-1}$ in the 3rd law entropy corresponds to a variation in the barrier to internal rotation of about ±700 cal/mol. This range easily includes the barrier of 4300 cal/mol derived by Karle (12) from analysis of the electron-diffraction data (8). Uncertainty in the entropy of this table should not exceed 0.5 cal $K^{-1}\ mol^{-1}$ at 1000 K.

Enthalpy of Formation

The enthalpy of formation of $C_2H(g)$ is not well established; however, we can place reliable upper and lower limits on the value.

Cottrell (1), gives an upper limit for the C-H bond dissociation energy in acetylene, $\Delta_{at}H°$(HCC-H) <121 kcal. This was obtained from the fact that ultra violet light of 121 kcal mol^{-1} energy causes acetylene to from diacetylene and hydrogen; assuming that this process occurs through the CCH radical, the light energy is equated with $\Delta_{at}H°$(HCC-H). This value of $\Delta_{at}H°$(HCC-H) gives an upper limit for $\Delta_f H°$(CCH, g, 298.15 K) <123 kcal mol^{-1}.

A lower limit for $\Delta_{at}H°$(HCC-H) is obtained from a consideration of the C-H bond dissociation energies in ethylene and ethane, $\Delta_{at}H°(C_2H_3\text{-}H)$ = 103 kcal and $\Delta_{at}H°(C_2H_5\text{-}H)$ = 98 kcal. The heats of formation of the C_2H_3 and C_2H_5 radicals and their parent compounds are taken from Benson (2). The vibrational frequency of the C-H stretch increases steadily form ethane to ethylene and acetylene. Similarly we expect the bond strength to increase, and so $\Delta_{at}H°$(HCC-H) >103 kcal; this yields $\Delta_f H°$(CCH, g, 298.15 K) >105 kcal mol^{-1}.

Coats and Anderson (3), obtained several values for $\Delta_f H°$(CCH, g, 298.15 K) from mass-spectroscopic measurements; their values range from 110 kcal mol^{-1} to 153 kcal mol^{-1}, but they chose to adopt 112± 3 kcal mol^{-1}.

Our adopted value of $\Delta_f H°$(CCH, g, 298.15 K), 114±7 kcal mol^{-1}, (476.976±29 kJ mol^{-1}), is 2 kcal smaller than that estimated by Tsang et al (4).

Heat Capacity and Entropy

The molecule is assumed to be linear; the bond lengths are assumed to be the same as in acetylene and were taken from Sutton (5).

The vibrational frequencies are those estimated by Plooster and Reed (6). It should be noted that the values of the free energy function given by Plooster and Reed (6) are incorrect due to the neglect of the electronic contributions.

The electronic levels, $X^2\Sigma$ and $A^2\Pi$, were estimated by analogy with those of CN(g) which is isoelectronic; this assumption holds very well in the parent molecules HCCH and HCN (7). The molecule $C_2H_2^+$, which is also isoelectronic with CCH, is predicted to have a $^2\Pi$ ground state by Herzberg (7).

Bond Distances: C-C = 1.204 Å C-H = 1.055 Å C-Cl = 1.637 Å
Bond Angles: Cl-C-C = 180° C-C-H = 180°
Rotational Constant: $B_0 = 0.188645\ cm^{-1}$

Enthalpy of Formation

The value of $\Delta_f H°(298.15\ K) = 51.1\ kcal\ mol^{-1}$ is calculated from the estimated $\Delta_r H°(298.15\ K) = -53 \pm 10\ kcal\ mol^{-1}$ for $HC{\equiv}CCl(g) + Cl_2(g) \rightarrow CHCl{=}CCl_2(g)$, using $\Delta_f H°(CHCl{=}CCl_2, g, 298.15\ K) = -1.86\ kcal\ mol^{-1}$ (1). The value of $\Delta_r H°(298.15\ K)$ is assumed to be the same as that for the reaction $HC{\equiv}CH(g) + Cl_2(g) \rightarrow CHCl{=}CHCl(g)$, using $\Delta_f H°(C_2H_2, g, 298.15\ K) = 54.19\ kcal\ mol^{-1}$ (1) and $\Delta_f H°(CHCl{=}CHCl, g, 298.15\ K) = 1.2\ kcal\ mol^{-1}$ (2).

Heat Capacity and Entropy

The linear molecular structure and bond distances were determined from the microwave spectrometrical studies by Tyler and Sheridan (3). Their results are in good agreement with those of Westenberg et al.(4).

The vibrational frequencies were observed in the infrared spectra by Hunt and Wilson (5), and Richardson and Goldstein (6).

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: $C_{\infty v}$

Bond Distances: C-F = 1.279 Å C-C = 1.198 Å C-H = 1.053 Å

Bond Angles: F-C-C = 180° C-C-H = 180°

Rotational Constant: $B_0 = 0.323577\ cm^{-1}$

Enthalpy of Formation

The enthalpy of formation is estimated by assuming that the C-C bond strength is the average of those in C_2F_2(113 kcal) and C_2H_2(229 kcal). Combining the average value (171 kcal) with the enthalpies of formation of CF and CH from the JANAF Tables, yields $\Delta_f H°(C_2HF, g, 298.15\ K) = 30 \pm 15\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

Hunt and Wilson (1) and Brown and Tyler (2), have reported the infrared spectrum and have assigned the fundamental frequencies. The frequencies used in the present table are median values of the two sets and are generally within 5 cm^{-1} of each set.

The molecule has been shown to be linear by Tyler and Sheridan (3), who reported the rotational constant B_0.

The electronic ground is assumed to be $^1\Sigma$ by analogy with C_2H_2.

Values of α_1 not available.

Enthalpy of Formation

Taken from Wagman et al. (1).

Heat Capacity and Entropy

Gordon (2) has used the constants listed above to calculate $C_p°$ from 298.15 K to 6000 K by the method of Pennington and Kobe (3). The constants are from Bell and Nielsen (4) and Allen et al. (5). Heat capacities below 298.15 K have been calculated for a rigidly rotating harmonic oscillator.

Enthalpy of Formation

The enthalpy of combustion of ethylene was measured by Rossini and Knowlton (1). From the value, $\Delta_r H°(298.15\ K) = -337.28 \pm 0.07$ kcal mol^{-1} for the reaction $C_2H_4(g) + 3\ O_2(g) = 2\ CO_2(g) + 2\ H_2O(\ell)$, the enthalpy of formation, $\Delta_f H°(298.15\ K)$, for $C_2H_4(g)$ was derived to be 12.54 ± 0.07 kcal mol^{-1}. The values of $\Delta_f H°(298.15\ K)$ for $CO_2(g)$ and $H_2O(\ell)$ used for calculation were obtained from Rossini et al. (2).

Heat Capacity and Entropy

The molecular structure, bond distances and angles were obtained from Allen and Plyler (3). The vibrational frequencies were taken from Smith and Mills (4). Eight of the twelve frequencies were reported by Arnett and Crawford (5); Crawford et al. (6); Stoicheff (7); Feldman et al. (8); and Allen and Plyler (3). Herzberg (9) also reported the vibrational frequencies for ethylene as 3019.3 (1), 1623.3 (1), 1342.4 (1), 825.0 (1), 3272.3 (1), 1050 (1), 949.2 (1), 943 (1), 3105.5 (1), 995 (1), 298 .5 (1) and 1443.5 (1) which are very close to the values adopted. The infrared and Raman spectra of ethylene before 1945 have been summarized by Herzberg (9). The molecular structure of ethylene was also determined by Bartell and Bonham (10). Their results, r(C-H) = 1.085 Å, r(C-C) = 1.334 Å and H-C-H = 116 are in excellent agreement with the values adopted. The principal moments of inertia are $I_A = 0.5763 \times 10^{-39}$, $I_B = 2.8004 \times 10^{-39}$ and $I_C = 3.3767 \times 10^{-39}$ g cm^2.

Ground State Quantum Weight: 1 σ = 2

Point Group: C_{2v}

Bond Distances: C-H = 1.0802 Å C-O = 1.4363 Å C-C = 1.4728 Å

Bond Angles: H-C-H = 116° 51' H_2-C-C = 158° 5' H_2-C-O = 142° 45.6'

Product of the Moments of Inertia: $I_A I_B I_C = 7.42728 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of combustion of ethylene oxide (g) was determined by Pell and Pilcher (1) and Crog and Hunt (2) as -312.15±0.14 and -312.55±0.20 kcal mol^{-1}, respectively. The corresponding value of $\Delta_f H°(C_2H_4O, g, 298.15\ K)$ was evaluated to be -12.58±0.15 and -12.19±0.22 kcal mol^{-1}. The former value is adopted.

Heat Capacity and Entropy

The vibrational frequencies were taken from Lord and Nolin (3). The infrared and Raman spectra of ethylene oxide have also been examined by Linnett (4) and Thompson and Cave (5). The vibrational frequencies assigned were slightly different from the ones reported by Lord and Nolin (3). As a result of analogies between ethylene oxide and ethylene imine, small changes of Lord and Nolin's assignment have been made by Potts (6). The bond distances and angles were obtained from Cunningham et al. (7). The investigation of the structure of ethylene oxide by electron diffraction was reported by Ackermann and Mayer (8) and Igarashi (9). The principal moments of inertia are: $I_A = 3.2793 \times 10^{-39}$, $I_B = 3.8059 \times 10^{-39}$ and $I_C = 5.9511 \times 10^{-39}$ g cm^2.

The calculated heat capacities (307.2-371.2 K) are in good agreement with the experimentally measured ones reported by Kistiakowsky and Rice (10).

Ground State Quantum Weight: [1] $\sigma = 4$

Point Group: [D_{2h}]

Bond Distances: K-C = [2.75] Å C-N = [1.16] Å

Bond Angles: N-C-K = [140]° C-K-C = [100]° K-C-K = [80]°

Product of the Moments of Inertia: $I_A I_B I_C = [2.948540 \times 10^{-112}]\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°((KCN)_2, g, 298.15\ K)$ was calculated based on an estimated enthalpy of dissociation, 40 kcal mol^{-1} for the reaction $(KCN)_2(g) \rightarrow 2\ KCN(g)$, which was obtained by comparison with that for $(NaCN)_2(g)$.

Heat Capacity and Entropy

The molecular structure and bond angles were assumed to be the same as those for KCN(cr) reported by Bijvoet and Lely [1]. The C-N bond distance was assumed to be the same as that for KCN(g), and the K-C bond distance was assumed to be 10% longer than that in KCN(g). The vibrational frequencies were estimated by comparison with those for $K_2F_2(g)$. The last six frequencies were adopted from the bending and asymmetric stretching frequencies for KCN(g). The three principal moments of inertia are: $I_A = 40.5737 \times 10^{-39}$, $I_B = 67.3413 \times 10^{-39}$ and $I_C = 107.9149 \times 10^{-39}$ g cm^2.

Bond Angle: C-N-C = 180°

Rotational Constant: B_0 = 0.452740 cm^{-1}

Enthalpy of Formation

Merer and Travis (1) state that the observed bond length in CNC(g) indicates double-bonded CN links. The value of the C = N dissociation energy is derived as 147 kcal from the enthalpy of combustion of n-butyl-isobutylidine amine determined by Coates and Sutton (2). However, due to possible extra binding energy from the unpaired electron, we assume here a slightly higher value of 160 kcal. This yields a $\Delta_f H°$(CNC, g, 298.15 K) = 133 kcal mol^{-1}. It is also possible to calculate another value by assuming that the ratio of the enthalpy of atomization of Si_2N to that of C_2N(g) is equal to the ratio of the dissociation energies of SiN(g) and CN(g); by this method $\Delta_f H°$(CNC, g, 298.15 K) = 144 kcal mol^{-1}.

Heat Capacity and Entropy

Merer and Travis (1) have observed the ultraviolet absorption sectrum of the CNC radical. They ave assigned the configuration, bond distance, and the electronic levels. In addition, they have derived ν_2; the remaining frequencies are estimated by comparison with the $^1\Pi$ state of C_3(g), which has been assigned by Weltner and McLeod (3).

240 (2)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distances: C-N = 1.157 Å C-C = 1.380 Å

Bond Angles: C-N-N-C = 180°

Rotational Constant: $B_0 = 0.157545 \pm 0.00015\ cm^{-1}$

Enthalpy of Formation

Knowlton and Prosen (1) report $\Delta_f H°(298.15\ K) = -261.94 \pm 0.43$ kcal for the reaction $C_2N_2(g) + 2\ O_2(g) \rightarrow 2\ CO_2(g) + N_2(g)$. When corrected for a change in the atomic weight of carbon, this becomes $\Delta_f H°(298.15\ K) = -261.95 \pm 0.43$ kcal, whence $\Delta_f H°(298.15\ K)$ for $C_2N_2(g)$ is found to be 73.87 ± 0.43 kcal mol^{-1}.

Heat Capacity and Entropy

Langseth and Moller (2) determined the vibrational frequencies by Raman spectroscopy. Moller and Stoicheff (3) determined B_0 by Raman spectroscopy and calculated the bond lengths listed above. These agree with lengths found from electron-diffraction measurements by Langseth and Moller (2) (CN distance = 1.15 Å, CC distance = 1.38 Å) and Pauling et al. (4) (CN distance = 1.16±0.02 A, CC distance = 1.37±0.02 Å). From measurements reported by Ruehrwein and Giauque (5), S°(298.15 K) is calculated by the 3rd law to be 57.63 cal K^{-1} mol^{-1}, in satisfactory agreement with the value calculated here.

Enthalpy of Formation

The mass spectra of vapors from samples of NaCN have been observed by Porter (1) at temperatures around 1000 K. The results indicate that the compound evaporates as NaCN(g) and $Na_2(CN)_2$(g). A comparison of relative ion currents produced by electron bombardment of NaCN vapors effusing from single-and double-oven-type Knudsen cells, yielded information on the partial pressures of monomer and dimer. Based on the partial pressures for NaCN(g) and $(NaCN)_2$(g) reported at temperatures, 903-1049 K, the vapor pressures of $(NaCN)_2$(g) over NaCN(ℓ), 1078.2-1626.2 K, were calculated from the total vapor pressure measurements reported by Ingold (2). By the 2nd and 3rd law methods, the values of $\Delta_{vap}H°(298.15\ K)$ (ℓ → dimer) were evaluated to be 38.89 and 38.21 kcal mol^{-1}, respectively. Using the 3rd law value, the enthalpy of formation for $(NaCN)_2$(g) was evaluated.

Heat Capacity and Entropy

The molecular structure, bond distances and C-Na-C bond angle were estimated by Porter (1). The vibrational frequencies were *estimated by comparison with those for* NaCl(g). The last six frequencies were the bending and asymmetric stretching frequencies for NaCN(g). The principal moments of inertia are: I_A = 13.5707 x 10^{-39}, I_B = 51.0944 x 10^{-39} and I_C = 64.6652 x 10^{-39} g cm^2.

Rotational Constant: B_0 = [0.408483] cm^{-1}

Enthalpy of Formation

The adopted enthalpy of formation, $\Delta_f H°(C_2O, g, 298.15\ K) = 68.5\ kcal\ mol^{-1}$, was calculated from the enthalpy of reaction $\Delta_r H°(298.15\ K) = 65.5\ kcal\ mol^{-1}$ for $C_3O_2(g) = C_2O(g) + CO(g)$ using all JANAF functions (dated Sept. 30, 1965). The value of $\Delta_r H°$ was obtained from the 3rd law calculation of the equilibrium constant (Kp = 3.3 x 10^{-6} atm at 1060 K) which was determined in the studies of decomposition rate of $C_3O_2(g)$ by Palmer and Cross (1).

Jacox, Milligan, Moll, and Thompson (2) have observed the photodissociation of C_2O near 5000 Å which corresponds to a minimum of 57 kcal mol^{-1} for $C_2O(g) + C(g) + CO(g)$. This yields $\Delta_f H°(C_2O, g, 298.15\ K) \leq 87\ kcal\ mol^{-1}$ which was not adopted because the irradiation was not monochromatic and thus possibly contained all wavelengths below 5000 Å.

Heat Capacity and Entropy

Jacox et al. (2) have observed three vibrational fundamentals in the infrared spectrum by matrix isolation, and suggested a linear structure with $^3\Sigma$ ground state for the CCO radical (g). They also estimated the bond distances C-C = 1.160 Å and C-O = 1.279 Å based on the structural analogy between the carbon suboxide and the CCO radical. Bayes (3) has predicted that the ^1Z and $^1\Sigma$ states lie respectively 0.5 and 0.8 eV above the ground state. These two elctronic states have been included in the tabulation.

Enthalpy of Formation

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite (1), SiC-silison (2) and boron-carbon-silicon (3). 3rd law analysis of the partial pressures of C_2Si and Si lead to the concordant values 146.7, 149.0 and 146.0 kcal mol^{-1}. Although the drifts all suggest that the entropy of C_2Si may be about 3.5 less than tabulated, this is of doubtful significance because the uncertainty bands are so large. The low condensation coefficient suggested by Drowart (2) may also be involved. Rates of free evaporation reported by Voronin (4) lead to apparent pressures which are smaller by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of $\Delta_f H°(298.15\ K)$ = 147±7 kcal mol^{-1} includes allowance for the unlikely possibility that the entropy may be in error by up to 3.5 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

The known molecular constants are from the assignments of Weltner and McLeod (5). These authors observed the infrared spectrum, emission spectrum and visible absorption spectrum of C_2Si in matrix isolation. The matrix data allowed more certain assignment of the A-X band system of the gas as observed by Kleman (6) and McKellar (7). Weltner concluded that this system probably involves transitions between a $^1\Sigma^+$ ground state and a $^1\Pi$ excited state. The two stretching frequencies were observed in the matrix infrared spectrum, whereas the bending mode, 300 cm^{-1}, was derived solely from the analysis of the A-X band system. The analysis presumed a linear unsymmetrical structure for the molecule.

A $^3\Pi$ excited state is assumed to lie 7000 cm^{-1} below the $^1\Pi$ state, which presumably arises from the same molecular orbital configuration. The effect of the estimated level is to increase the entropy by about 0.2 and 1.8 cal K^{-1} mol^{-1} at 3000 and 6000 K. Bond distances are estimated by comparison with those in Si_2, C_2 and C_3.

Point Group: $D_{\infty h}$
Bond Distances: C-C = 1.277 Å
Bond Angle: C-C-C = 180°
Rotational Constant: $B_0 = 0.430334\ cm^{-1}$

Enthalpy of Formation

Drowart et al. (1) have measured mass spectrometrically the ion intensity ratio C_3^+/C^+ as a function of temperature from 1800 to 2700 K. We derive from a 2nd law analysis of their data $\Delta_f H°(2200\ K) = 185.2 \pm 3.3$ kcal, and $S°(2200\ K) = 74.9 \pm 2.8$ cal $K^{-1}\ mol^{-1}$ by calculation of the absolute pressure from the vapor pressure of monatomic carbon and a relative ionization cross-section ratio of 2.3. The entropy uncertainty includes 1.3 cal $K^{-1}\ mol^{-1}$ for uncertainty in the absolute pressure. Several earlier mass-spectrometric determinations (2, 3, 4) are in reasonable agreement. The absolute magnitude of the pressure is also confirmed by the work of Thorn and Winslow (5) who measured the total pressure of all species over graphite as 1.2 to 4.8 x 10^{-7} atm at 2400 K. Subtracting the JANAF values for C and C_2 we obtain C_3 = 5.4 x 10^{-8} to 2.2 x 10^{-7} atm, which compares with Drowart's value of 3.3 x 10^{-8} to 1.3 x 10^{-7} atm. The 2nd law enthalpy of formation is reported (5) to be $\Delta_f H°(2400\ K) = 184.4$ but the range is only 80 K. It does, however, confirm the magnitude of the mass-spectrometric values for both enthalpy and entropy. We have adopted a enthalpy of formation within the uncertainty limits of Dowart's measurements which with the adopted functions yields pressures in the 2000-3000 K range consistent with the measurements. We were not able to generate functions which agree exactly with the 2nd law entropies, since even direct summation over only the observed levels of the bending frequency gives an entropy which is already too large.

Heat Capacity and Entropy

The stretching frequencies are from Merer (6), Weltner et al. (7) and Weltner and McLeod (8). The bending frequency and its harmonics are from Gausset et al. (9) and Merer (6). The rotational constant and bond distance are from Gausset et al. (9).

As indicated briefly above, the calculated entropy of C_3 gas is higher than the experimental value even when a summation is performed only over the observed first six levels of the bending frequency. Treatment of the vibration as a harmonic oscillator or as a anharmonic oscillator gives values considerably higher. Strauss and Thiele (10) have also calculated functions based on a quartic potential function which still yields values several units higher than the experiments. In order to reduce the entropy to the approximate range of the measurements we have made the assumption that the potential function is of an unusual form above the sixth vibrational level. We assume that the large amplitude of the bending vibration causes a drastic change in the function, possibly due to the increasing repulsion between end carbons, as the amplitude increases. Thus, we assume a very steeply rising potential above the sixth vibrational level. We have chosen to represent this part of the potential by a harmonic oscillator of 650 cm^{-1}. The choice of 650 cm^{-1} is arbitrary, but is not unreasonable for a bending vibration, and yields functions which approximate the experimental data.

In order to explain the observed spectrum of C_3O_2, a molecule with a bending frequency of 63 cm^{-1}, Smith and Barrett (11) have proposed that potential maxima occur in the bending potential away from linearity. Thus, the adoption of an unusual potential function for C_3 bending may be justifiable. We do not claim that our functions are necessarily correct but only that they include all known facts and satisfy the experimental equilibrium observations. Further investigation of the carbon vapor pressure and of the higher vibrational levels of C_3 is desirable.

$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The $\Delta_f H°(298.15\ K) = -51.55 \pm 1.6$ kcal mol^{-1} is the average value of $\Delta_f H°(298.15\ K) = -49.7 \pm 1.2$ kcal mol^{-1} by King and Armstrong (1) and that of $\Delta_f H°(298.15\ K) = -53.4 \pm 2.0$ kcal mol^{-1} by Mah (2). Both measured the enthalpy of reaction $Al_4C_3(cr) + 6O_2(g) + 2Al_2O_3(cr, \alpha) + 3CO_2(g)$ and used their $\Delta_r H°(298.15\ K)$ and the $\Delta_f H°(298.15\ K)$ of $Al_2O_3(cr)$ and $CO_2(g)$ to calculate the $\Delta_r H°(298.15\ K)$ of $Al_4C_3(cr)$. The $\Delta_r H°(298.15\ K)$ measured by King and Armstrong was -1033.3 ± 1.1 kcal mol^{-1}, the $\Delta_r H°(298.15\ K)$ measured by Mah (2) was -1029.6 ± 1.9 kcal mol^{-1}.

Heat Capacity and Entropy

The low temperature heat capacities, 18-390 K, were measured by Saba and Furukawa (3). The high temperature heat capacities, 273-1173 K, were measured by Victor et al. (4). These two sets of heat capacity data were joined smoothly and extrapolated to 2000 K by Saba and Furukawa (3). The values of $C_p°$ above 2000 K were estimated by extrapolation graphically. $S°(298.15\ K)$ was reported by Saba and Furukawa (3), using $S°(extrap.\ 20\ K) = 0.013$ cal $K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} was estimated by Ruff and Jellinek (5).

Aluminum Carbide (Al_4C_3) C_3Al_4(cr)

$S°(298.15\ K) = 200.983 \pm 1.26\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -163.51 \pm 16.7\ kJ\ mol^{-1}$ 1
$\Delta_f H°(298.15\ K) = -160.67 \pm 16.7\ kJ\ mol^{-1}$

Enthalpy of Formation

Mah (1) determined the heat of combustion of Cr_7C_3(cr) using oxygen bomb calorimetry. She reported $\Delta_c H°(298.15\ K)$ = -1193.0±0.9 kcal mol^{-1} based on the reaction $Cr_7C_3(cr) + 33/4\ O_2(g) = 7/2\ Cr_2O_3(cr) + 3\ CO_2(g)$. Using JANAF auxiliary data (2), we calculate $\Delta_f H°(298.15\ K)$ = -38.4 kcal mol^{-1} for Cr_7C_3(cr). Mah (1) reported that the six combustion runs gave 99.90 to 99.84% completion of combustion. Corrections for incomplete combustion, formation of small amounts of CO(g), and impurities were made by Mah (1). These corrections amount to no more than 1.04% of the $\Delta_c E$ value.

The pressures of CO(g) in equilibrium with a Cr_2O_3-Cr_7C_3-$Cr_{23}C_6$ mixture have been measured by Kelley et al. (3) and Kulkarni and Worrell (4). Kelley et al. (3) also examined the Cr_2O_3-Cr_3C_2-Cr_7C_3 system. Kulkarni and Worrell (4) measured the CO pressure using a torsion effusion technique while Kelley et al. (3) measured the pressure manometrically. The results of our analyses are tabulated in the following table. In all cases we have assumed unit activity for the condensed species.

Source	T/K	Data Points	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°298.15\ K)$ kcal mol^{-1}
(3)	1307-1497	9	A	994.44	970.74	-16.9±4.3	-41.53
(4)	1111-1250	11[b]	B	220.48	218.99	- 1.3±0.6	-35.18
(3)	1505-1723	15[c]	B	211.34	220.89	5.8±2.0	-35.81

[a]Reactions: (A) $5\ Cr_2O_3(cr) + 27\ Cr_3C_2(cr) = 13\ Cr_7C_3(cr) + 15\ CO(g)$ (B) $Cr_2O_3(cr) + 3\ Cr_7C_3(cr) = Cr_{23}C_6(cr) + 3\ CO(g)$.
[b]1234.6, 1250.0 K points deleted due to statistical test; effective range is now 1111-1220 K.
[c]1524 K point deleted due to statistical test.

We adopt $\Delta_f H°(298.15\ K)$ = -38.4±4.0 kcal mol^{-1} for Cr_7C_3(cr) based on the combustion data of Mah (1). The equilibrium studies by Kulkarni and Worrell (4) and Kelley et al. (3) are in reasonable agreement with the adopted value. Equilibrium studies involving Cr_7C_3(cr) by Hancock and Pidgeon (5), Alekseev and Shvartsman (6), and Bolgar et al. (7) are not considered (2).

Heat Capacity and Entropy

The heat capacity (54-295 K, 29 pts.) and enthalpy (480-1580 K, 15 pts.) have been measured by Kelley et al. (3). Using the Debye function suggested (3), we calculate S°(50 K) = 1.679 cal K^{-1} mol^{-1} and H°(50;0) = 62.66 cal K^{-1} mol^{-1}. The adopted heat capacity curve is based solely on the above mentioned study with the constraint that the heat capacity values derived from the enthalpy data join smoothly with the low temperature heat capacity values near 298.15 K. The observed $C°_p$ values deviate from the adopted values within ±0.2% for T < 298.15 K. The enthalpy data agrees within ±0.35% with the tabulated values except for the 1263.4 K data (1.66% or ~1.0 kcal mol^{-1} too low) and the two points at 1545.1 and 1578.1 K which were not included in the polynomial curve fit (3). The polynomial is used to extrapolate $C°_p$ values above 1500 K.

Phase Data

Storms (8) has summarized much of the phase data for the chromium carbides and reported a hexagonal structure for Cr_7C_3. The homogeneity range for Cr_7C_3 is not known (8).

Decomposition Data

The tentative phase diagram for the Cr-Cr_3C_2 system as proposed by Storms (8) indicated an incongruent melting at 2053 K.

830(1)	1573(1)	63(2)
	577(2)	

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: $D_{\infty h}$
Bond Distances: C-C = 1.28 Å C-O = 1.16 Å
Bond Angles: C-C-C = 180° O-C-C = 180°
Rotational Constant: $B_0 = 0.073337\ cm^{-1}$

Enthalpy of Formation

Kybett et al. (1) have determined the enthalpy of combustion of the liquid form under its own pressure using the sample from the heat capacity determinations (2).

The average of four determinations gave $\Delta_f H°(\ell, 298.15\ K) = -28.03 \pm 0.24$ kcal mol^{-1}; the authors report -29.03 due to an arithmetic error. The sample was 99.98 mole percent pure. McDougall et al. (2) measured $\Delta_{vap} H°(230\ K) = 6.421 \pm 0.012$ kcal mol^{-1} from which we calculate $\Delta_{vap} H°(298.15\ K) = 5.65 \pm 0.2$ kcal mol^{-1}. Thus the enthalpy of formation of the gas is found to be 22.38 ± 0.44 kcal mol^{-1}.

Heat Capacity and Entropy

There has been considerable controversy as to the configuration of this molecule and the assignment of its vibrational frequencies. However, the evidence seems fairly conclusive for the linearity of the molecule from the work of Lafferty et al. (3) and Miller et al. (4). The rotational constant adopted here is that found by Lafferty et al. (3) and the vibrational frequencies are those reported by Miller et al. (4), except for ν_7 which is taken from Miller et al. (5) and Borgers (7). The low frequency Π_u mode is confirmed by the work of McDougall et al. (2), who measured the low temperature entropy of C_3O_2(cr) and (ℓ) and also the enthalpy of vaporization. From a comparison of the entropy calculated statistically and that measured, they conclude $\nu_7 = 63.2\ cm^{-1}$. The values adopted are confirmed by 3rd law analysis of the vapor pressure data of McDougall et al. (5) which indicates a enthalpy of vaporization in fair agreement with their calorimetric value. The drift in the 3rd law analysis indicates that the entropy of the solid is too low or that of the gas is too high by 1 cal $K^{-1}\ mol^{-1}$. Alternatively as systematic error in the pressure measurements could have caused this deviation.

The bond distances are taken from the electron diffraction experiments of Livingston et al. (6) and are in good accord with the adopted rotational constant.

Enthalpy of Formation

The enthalpy of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained $\Delta_f H°(2400\ K) = 226 \pm 7$ kcal mol^{-1}. This was obtained from a 2nd law analysis of the ion intensity ratio C_4^+/C^+ over a temperature range of 2200-2700 K. the absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 4.96, yields a 2nd law entropy at 2400 K of 90.5 ± 3 cal K^{-1} mol^{-1}. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of ± 4.5 cal K^{-1} mol^{-1}. The enthalpy of formation at temperatures other than 2400 K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C_4 are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C_4 were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C_3, C_3O_2 and CO_2, but the discovery of very low bending frequencies in C_3 and C_3O_2 complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C_4 and C_5. These vibrational frequencies yield high entropies outside the limits of the 2nd law determination. Since these frequencies are estimates based on a basically triatomic correlation we have chosen to adopt two bending frequencies of 550 cm^{-1} rather than the 200 cm^{-1} and 440 cm^{-1} estimated by Sandborn. In addition we have assumed that the ground state arising from a π^2 term is $^1\Sigma$ and not $^3\Sigma$ as assumed by Pitzer and Clementi. The basis for both these changes is to make the functions conform to the only available measured data. Use of the present table will yield values for the vapor pressure of C_4 in excellent agreement with the measurements in the 2000-3000 K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The strectching frequencies are from Sandborn (3) and the bond length is estimated from C_3.

TETRAMETHYLSILANE ($Si(CH_3)_4$) IDEAL GAS M_r = 88.22478

$S°(298.15\ K) = 361.189\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-286.604]\ kJ\ mol^{-1}$

Enthalpy of Formation

Source unknown.

Heat Capacity and Entropy

$C°_p$ taken from Janz et al. (1).

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distances: C≡N = 1.14 Å C-C = 1.37 Å C≡C = 1.19 Å

Rotational Constant: $B_0 = 0.045397\ cm^{-1}$

Enthalpy of Formation

Armstrong and Marantz (1), measured the enthalpy of combustion of the liquid for which they obtain a $\Delta_f H°(298.15\ K)$ of 120.6 kcal mol^{-1} using 94.05 kcal mol^{-1} for $\Delta_f H°(CO_2, g, 298.15\ K)$. They calculate the $\Delta_f H°(C_4N_2, g, 298.15\ K)$ with a $\Delta_{vap}H$ taken from Saggiomo (2).

Heat Capacity and Entropy

Bond lengths determined by Miller and Hannan (3) from X-ray diffraction measurements on the solid. The vibrational frequencies were observed in the infrared and Raman by Miller et al. (4).

PREVIOUS: March 1961 (1 atm) CURRENT: March 1961 (1 bar)

$S°(298.15\ K) = [319.56 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 253.86 \pm 0.1\ K$

$\Delta_f H°(298.15\ K) = -631.78 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 13.832 \pm 0.021\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation is a weighted average based on enthalpy of combustion data of Smagina and Ormont (1) and Fischer et al. (2). The results of Smagina and Ormont (1) have been recalculated along the lines indicated by Sykes (3), using recent values of $\Delta_f H°(NiO, cr)$ (4) and other auxiliary data (5). Their corrected value of $\Delta_f H°(Ni(CO)_4, \ell, 298.15\ K)$ is -150.3±3.0 kcal mol^{-1} (average of 3 determinations using Pt fuse). Fischer et al. [2] made two sets of determinations yielding the following values of $\Delta_f H°(Ni(CO)_4, \ell, 298.15\ K)$; -150.3±0.5 kcal mol^{-1} (average of 5 determinations using benzoic acid fuse) and -152.3±0.5 kcal mol^{-1} (average of 4 determinations using Pt fuse). Fischer et al. (2) mention that the difference in their two sets of values may be due to hydration effects but a more likely explanation is higher uncertainties in the percentage combustion, as suggested by Sykes (3). Therefore, we adopt an uncertainty of ±2.0 kcal mol^{-1}.

Heat Capacity and Entropy

We adopt the smooth values of $C_p°$ (90-270 K) reported by Spice et al. (6). Values above 270 K are based on a linear extrapolation of liquid $C_p°$ values from 255-270 K. The $C_p°$ data reported by Duncan and Murray (7) were calculated from gas phase $C_p°$ data via a poorly defined procedure and show large deviations from the adopted $C_p°$.

The value of $S°(298.15\ K)$ is difficult to assess because of the lack of $C_p°$ data below 90 K. The adopted value of $S°(298.15\ K)$ is chosen so as to get the best agreement between second and third law analysis of the consistent vapor pressure data of Suginuma and Satozaki (8), Walsh (9), and Baev (10). This treatment results in a value of $S°(cr, 90\ K) = 23.95$ cal K^{-1} mol^{-1}. Spice et al. (6) had estimated a value of $S°(cr, 90\ K) = 20.6$ cal K^{-1} mol^{-1} based on comparisons (at 90 and 120 K) with a "standard" heat capacity curve.

Fusion Data

The adopted values of T_{fus} and $\Delta_{fus}H°$ are those reported by Spice et al. (6). The value of $\Delta_{fus}H°$ is the mean of three *calorimetrically determined values. Walsh (9) reported a value of* T_{fus} *approximately 2 K higher than the adopted value and* also reported that T_{fus} is very sensitive to purity of the $Ni(CO)_4$. However, we find the purity determinations of Spice et al. (6) more than compelling than those of Walsh (9).

Vaporization Data

The normal boiling point at 1 atm, T_{vap} = 315.4±0.2 K, is based on the vapor pressure measurements of Suginuma and Satozaki (8), Walsh (9) and Baev (10); fugacity corrections have not been made. See $Ni(CO)_4(g)$ table (5) for analysis of $\Delta_{vap}H°$.

Enthalpy of Formation

The value of $\Delta_f H°(g, 298.15\ K)$ is obtained from $\Delta_f H°(\ell, 298.15\ K)$ (1) by addition of the enthalpy of vaporization, $\Delta_{vap}H°(298.15\ K) = 7.22 \pm 1.5\ kcal\ mol^{-1}$. The adopted value of the enthalpy of vaporization is selected from our 3rd law analysis of the vaporization data given below and is based primarily on the data of Suginuma and Satozaki (2), Baev (3) and Walsh (4). The uncertainty has been increased above that indicated in the table below to account for uncertainties in the free energy functions of the liquid and gas. Fugacity corrections have not been applied but they are expected to be within the stated uncertainty. The enthalpy of vaporization at the boiling point, $\Delta_{vap}H°$, is the difference between $\Delta_f H°(g)$ and $\Delta_f H°(\ell)$ at the boiling point.

Data for the equilibrium $Ni(cr) + 4CO(g) = Ni(CO)_4(g)$ have been reviewed by Kipnis (7). The data show considerable scatter and this has been attributed to differences in chemical potential of nickel (sheet or powder) used in the reaction (7, 8). Values of $\Delta_f H°(298.15\ K)$ derived from these studies are less negative than the adopted value by several $kcal\ mol^{-1}$ and are less reliable due to uncertainty in the chemical potential of nickel.

Heat Capacity and Entropy

The adopted vibrational data, including anharmonicity, are from Jones et al. (9). The largest uncertainty in these assignments is in the frequency of the MCO bending vibration, ν_3. Jones et al. (9) chose 380 cm^{-1} based on a study of the spectra of substituted carbonyls by Bigorgne and Bouquet (10). Ross et al. (11) summarized values of S°(298.15 K) (96.2 to 99.8 $cal\ K^{-1}\ mol^{-1}$) obtained from various frequency assignments; most of this variation is due to alternate assignments for ν_3.

The adopted molecular structure data are from the electron diffraction study of Brockway and Cross (12) which conclusively indicates a tetrahedral structure. Moment of inertia calculations based on the adopted bond distances and angles yield $I_A = I_B = I_C = 8.01120 \times 10^{-38}\ g\ cm^2$.

The thermodynamic functions, including the effects of available vibrational anharmonicities, are calculated using the computer program of McDowell (13). Compared to a harmonic oscillator calculation using the same data the present results are identical at 298.15 K, while at 6000 K the entropy is 0.333 $cal\ K^{-1}\ mol^{-1}$ higher.

Enthalpy of Formation

The enthalpy of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained $\Delta_f H°(2400\ K) = 230 \pm 5$ kcal mol^{-1}. This was obtained from a 2nd law analysis of the ion intensity ration C_5^+/C^+ over a temperature range of 2200-2700 K. The absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 6.3, yields a 2nd law entropy at 2400 K of 103.7 ± 2 cal K^{-1} mol^{-1}. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of ± 3.5 cal K^{-1} mol^{-1}. The enthalpy of formation at temperatures other than 2400 K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C_5 are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C_5 were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C_3, C_3O_2 and CO_2, but the discovery of very low bending frequencies in C_3 and C_3O_2 complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C_4 and C_5. These vibrational frequencies yield high entropies outside the limits of the 2nd law determination. Since these frequencies are estimates, based on a basically triatomic correlation we have chosen to adopt three doubly degenerate bending frequencies of 550 cm^{-1} in place of the 130 cm^{-1}, 330 cm^{-1} and 520 cm^{-1} frequencies estimated by Sandborn (3). The basis for this change is to make the functions conform to the only available measured data. Use of the present tables will yield values for the vapor pressure of C_4 is excellent agreement with the measurements in the 2000-3000 K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The stretching frequencies are from Sandborn (3) and the bond length is estimated equal to that in C_3.

PREVIOUS: December 1969 (1 atm) CURRENT: December 1969 (1 bar)

$S°(298.15\ K) = 337.08 \pm 4\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 253.1 \pm 0.1\ K$

$\Delta_f H°(298.15\ K) = -766.09 \pm 7.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 13.226 \pm 0.013\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation is based on the enthalpy of combustion measurements of Cotton et al. (1). The average energy of combustion reported by these authors is -386.86 ± 1.7 kcal mol^{-1} which yields a value of $\Delta_c H°(298.15\ K) = -385.82 \pm 1.7$ kcal mol^{-1}. Using auxiliary JANAF data (2) we calculate the adopted value of $\Delta_f H°(298.15\ K) = -183.1 \pm 1.7$ kcal mol^{-1}. Earlier combustion work by Roth (3) and Mittasch (4) appears less reliable due to incomplete characterization of products.

Heat Capacity and Entropy

The adopted heat capacity is derived by merging the $C_p°$ data of Leadbetter and Spice (5) (22 - 287 K) with $C_p°$ data derived from the enthalpy measurements of Welty et al. (6) (302 - 387 K). Leadbetter and Spice report a small anomaly in $C_p°(cr)$ near 230 K which they attribute to the presence of a small amount of impurity; therefore we have smoothed through this anomaly. The heat capacity (5) and enthalpy data (6) of the liquid merge smoothly and yield a constant $C_p° = 55.876$ cal $K^{-1}\ mol^{-1}$ from the melting point to 387 K. We assume $C_p°$ remains constant at this value above this temperature.

The adopted value of $S°(298.15\ K)$ is obtained by the appropriate integration of $C_p°$ data assuming $S°(25\ K) = 3.49 \pm 1.0$ cal $K^{-1}\ mol^{-1}$. $S°(25\ K)$ is obtained by using a single Debye function with 18 degrees of freedom and $\theta_D = 155$ K as suggested by Leadbetter and Spice (5). The uncertainty in this procedure is rather large since a single Debye function fits the observed $C_p°$ data quite poorly.

Fusion Data

The adopted values of T_{fus} and $\Delta_{fus}H°$ are those reported by Leadbetter and Spice (5). The value of T_{fus} agrees well with that listed by Brynestad (7). For $\Delta_{fus}H°$ the only other value is $\Delta_{fus}H° = 3250 \pm 40$ cal $K^{-1}\ mol^{-1}$ reported by Mittasch (4). This is much less precise than the adopted value which is an average of two determinations.

Vaporization Data

The adopted boiling point, $T_{vap}(1\ atm) = \sim 377$ K, is based on the vapor pressure data of Trautz and Badstubner (8) and Baev (9); fugacity corrections have not been made. See the enthalpy of formation section of the $Fe(CO)_5(g)$ table (2) for details of the selected value of $\Delta_{vap}H°$.

Enthalpy of Formation

The adopted value of $\Delta_f H°(g, 298.15\ K)$ is obtained from $\Delta_f H°(\ell, 298.15\ K)$ (1) by addition of the enthalpy of vaporization, $\Delta_{vap}H°(298.15\ K) = 9.14 \pm 1.2$ kcal mol^{-1}. The adopted value of the enthalpy of vaporization is selected from our 3rd law analysis of the vaporization data below and is based primarily on the data of Trautz and Badstubner (2) and Baev (3). The uncertainty has been increased above that indicated in the table below to account for uncertainties in the free functions of the liquid and gas. Fugacity corrections have not been made but they are expected to be well within the stated uncertainty. The enthalpy of vaporization at the boiling point, $\Delta_{vap}H°$, is calculated from the difference between $\Delta_f H°(g)$ and $\Delta_f H°(\ell)$ at the boiling point.

Heat Capacity and Entropy

The selected vibrational data, including anharmonicity, are from Jones et al. (8). The largest uncertainty in these assignments is for ν_9; Jones estimates it to lie at 100±15 cm^{-1}. The uncertainty in this assignment coupled with unknown anharmonicities for the low frequency vibrational modes lead to rather large uncertainties in the thermal functions. Following the arguments of Jones we estimate an uncertainty at ±3.0 cal K^{-1} mol^{-1} in S°(298.15 K).

The adopted molecular structure data are from the electron diffraction data of Beagley et al. (9) which clearly indicate that the Fe-C axial bond is shorter than the Fe-C equatorial bond. Moment of inertia calculations based on the adopted bond distances and angles yield $I_A = 9.078946 \times 10^{-38}$ g cm^2 and $I_B = I_C = 1.046785 \times 10^{-37}$ g cm^2. The electron diffraction study of Almenningen et al. (10) is in excellent agreement with the adopted data although a slightly smaller difference between the axial and equatorial Fe-C bond lengths is indicated. This would lead to an insignificant difference in S°(298.15 K).

The thermodynamic functions, including the effects of available vibrational anharmonicities, are calculated using the computer program of McDowell (11). Compared to a harmonic oscillator calculation using the same data the present results are identical at 298.15 K, while at 6000 K the entropy is 0.407 cal K^{-1} mol^{-1} higher.

PREVIOUS: March 1978 (1 atm) CURRENT: March 1978 (1 bar)

CHROMIUM CARBIDE ($Cr_{23}C_6$) CRYSTAL M_r = 1267.974

$S°(298.15\ K) = 612.044 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -333.57 \pm 41.9\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -328.44 \pm 41.9\ kJ\ mol^{-1}$

Enthalpy of Formation

Mah (1) determined the enthalpy of combustion of $Cr_{23}C_6$(cr) using oxygen bomb calorimetry. Using auxiliary JANAF data (2) and the value $\Delta_c H°(303.15\ K) = -3604.2 \pm 1.5$ kcal mol^{-1} reported by Mah (1) for the combustion of $Cr_{23}C_6$, we calculate $\Delta_f H°(298.15\ K) = -78.5$ kcal mol^{-1} for $Cr_{23}C_6$(cr). The combustion equation is $Cr_{23}C_6(cr) + 93/4\ O_2(g) = 23/2\ Cr_2O_3(cr) + 6\ CO_2(g)$. The factor (23/2) makes the $\Delta_f H$ value for $Cr_{23}C_6$ extremely sensitive to the corresponding value for Cr_2O_3(cr). Of the nine combustion runs, Mah (1) reported complete combustion in three runs and 99.40 to 99.85% completion in the remaining six. Corrections for incomplete combustion, formation of small amounts of CO(g) and impurities were made by Mah (1). These corrections amount to no more than 0.7% of the $\Delta_c E°$ value.

The pressures of CO(g) in equilibrium with a $Cr_{23}C_6$-Cr_2O_3-Cr mixture have been measured by Kelley et al. (3) and Kulkarni and Worrell (4). Our analysis of their data is tabulated below. Kulkarni and Worrell (4) measured the CO pressure using a torsion effusion technique while Kelley et al. (3) measured the pressure manometrically. In all cases unit activity is assumed for the condensed species.

[a] effusion orifice diameter

[b] 1725, 1775 K points rejected due to statistical test.

[c] Reaction: (A)$Cr_{23}C_6$ (cr) + 2 Cr_2O_3(cr) = 27Cr(cr)

We adopt $\Delta_f H°(298.15\ K) = -78.5 \pm 10.0$ kcal mol^{-1} for $Cr_{23}C_6$(cr) based on the combustion data of Mah (1), with excellent support in the equilibrium studies by Kulkarni and Worrell (4) for orifice diameters of 1/4 and 1/3 mm. Kulkarni and Worrell (4) concluded that equilibrium was not obtained in the cell with the 1/2 mm orifice in order to provide an explanation for the low pressures observed. Equilibrium studies involving $Cr_{23}C_6$(cr) by Hancock and Pidgeon (5), Alekseev and Shvartsman (6), and Bolgar et al. (7) are not considered (2).

Heat Capacity and Entropy

The heat capacity (55-295 K, 29 pts.) and enthalpy (467-1697 K, 26 pts.) have been measured by Kelley et al. (3). When the *research was performed, Kelley et al. (3) considered the sample* to be Cr_4C. All the data are corrected to the composition $Cr_{23}C_6$, assuming that the sample actually contained excess Cr. The contribution of the assumed free Cr was subtracted from the reported heat capacity and enthalpy values using JANAF data for Cr (2). These corrections amount to 0.6 cal K^{-1} mol^{-1} at 55 K and 5.0 cal K^{-1} mol^{-1} at 295 K for the heat capacity data and are in a range of 1.00-1.85 kcal mol^{-1} for the enthalpy data. We adopt S°(50 K) = 4.861 cal K^{-1} mol^{-1} and H°(50;0) = 181.6 cal mol^{-1}. The enthalpy data are fit to a six term polynomial with a constraint to join smoothly in the 298.15 K region with the enthalpy derived from the heat capacity data. There is considerable scatter in the enthalpy data. Deviations of the observed data from the tabulated data are within ± 0.6% except for the 486.5 K data point which is approximately 1% (500 cal mol^{-1}) too high. The enthalpy polynomial is used to extrapolate the results to 2000 K.

Phase Data

Storms (8) has summarized the phase information in the Cr-C system and reported that $Cr_{23}C_6$ has a complex face-centered-cubic structure. The range of homogeneity for $Cr_{23}C_6$ is unknown (8).

Decomposition Data

The tentative phase diagram of the Cr-Cr_3C_2 system proposed by Storms (8) indicated that $Cr_{23}C_6$ has an incongruent melting point at 1793 K.

CALCIUM, ALPHA (Ca) CRYSTAL A_r = 40.08

Pearson Notation: cF4

$S°(298.15\ K) = 41.588\ J\ K^{-1}\ mol^{-1}$

$T_{trs}\ (\alpha \rightarrow \beta) = 716 \pm 3\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 0.930 \pm 0.08\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The thermal functions given here are those recommended by CODATA (1). The low temperature heat capacity of α-CA(cr) has been measured many times: Griffil et al. (1.8 - 4.2 K, 2), Agarwal and Betterton (1.1 - 4.2 K, 3), Roberts (1.5 - 20 K, 4), Clusius and Vaughen (10-200 K, 5), Gunther (22-62 K, 6), and Eastman and Rodebush (67 - 293 K, 7). The adopted heat capacity values are derived assuming that the heat capacity curve should lie below and be similar to the shape of the α-Sr(cr) curve, but remain higher than the Mg curve. The experimental data would imply a crossing of the curves below 300 K which does not appear reasonable. The adopted curve is in reasonable agreement with Griffil et al. (2), Roberts (4), and Clusius and Vaughen (5).

The high temperature heat capacities for the α and β phasis are estimates based on the experimental enthalpy studies in Zalensinskii and Zulinski (8), Jauch (9), and Eastman et al. (10) with the two constraints that the values mesh smoothly with the low temperature results and show a similarity with the Mg and Sr results.

Transition Data

See Ca(β, cr) tables for details.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: December 1968 CURRENT: September 1983

Pearson Notation: cI4

$S°(298.15\ K) = [43.070]\ J\ K^{-1}\ mol^{-1}$

$T_{trs}\ (\alpha \rightarrow \beta) = 716 \pm 3\ K$

$T_{fus}(\beta \rightarrow \ell) = 1115 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [1.056]\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 0.930 \pm 0.08\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 8.540 \pm 0.10\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Ca(β, cr) is calculated from that of the Ca(α, cr) by adding the enthalpy of transition and the difference in enthalpy, H°(716 K) − H°(298.15 K), between Ca(α, cr) and Ca(β, cr).

Heat Capacity and Entropy

The high temperatures heat capacities for the α and β phases are estimates based on the experimental enthalpy studies in Zalinsinski and Aulinski(1), Jauch (2), and Eastman et al. (3) with the two constraints that the values mesh smoothly with the low temperature results and show a similarity with the Mg and Sr results.

Transition and Fusion Data

According to Pearson (4), calcium exists in two crystalline modifications. The low temperature phase (α) has a face - centered - cubic (cF4) structure, as does α-Sr(cr). The high temperature phase (β) has a body - centered - cubic (cI2) structure, as does β - Sr(cr). In comparison, magnesium has a hexagonal - close - packed structure. The β-Ca(cr) region of stability is 716 ± 3 K to 1115 ± 2 K (5).

The enthalpies of transition and fusion are the values determined by Chiotti et al. (6) using an adiabatic calorimeter.

Sublimation Data

See the ideal gas table for details.

CALCIUM (Ca) LIQUID A_r = 40.08

$S°(298.15\ K) = [45.510]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [7.788]\ kJ\ mol^{-1}$

$T_{fus}\ (\beta \rightarrow \ell) = 1115 \pm 2\ K$ $\Delta_{fus}H° = 8.540 \pm 0.10\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the liquid is calculated from that of Ca(β, cr) by adding the enthalpy of fusion and the difference in enthalpy, H°(1115 K) - H°(298.15 K), between Ca(β, cr) and the liquid.

Heat Capacity and Entropy

The heat capacity of the liquid is chosen to be a value intermediate between the adopted values for Mg(ℓ) and Sr(ℓ).

Fusion Data

See the β-Ca(cr) table for details.

Vaporization Data

T_{vap} (1 bar) is calculated as the temperature at which $\Delta_r G° = 0$ for the process Ca(ℓ) = Ca(g). $\Delta_{vap}H°$ is calculated as the difference in the enthalpies of formation between the ideal gas and liquid at T_{vap}.

See the ideal gas table for details.

CALCIUM (Ca) IDEAL GAS A_r = 40.08

IP (Ca, g) = 49305.96 ± 0.08

$S°(298.15\ K)$ = 154.886 ± 0.020 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 177.3 ± 0.8 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = 177.8 ± 0.8 kJ mol^{-1}

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1S_0$	0.00	1
$^3P_0$	15157.901	1
$^3P_1$	15210.063	3
$^3P_2$	15315.943	5

Enthalpy of Formation

The adopted enthalpy of formation value for Ca(g), $\Delta_f H°(298.15\ K)$ = 177.8±0.8 kJ mol^{-1}, is that recommended by CODATA (1). This value was calculated, according to CODATA, from the vapor pressure measurements by Bogoslovskii et al. (773-1023 K, 2), Smith (844-965 K, 3), Bohdansky and Schins (1313-2060 K, 4), Schins et al. (1558-2115 K, 5). The study by DeMaria and Piacente (1126-1300 K, 6), and others cited in Hultgren et al. (7) were also considered.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Sugar and Corliss (8), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels (for n < 80) and cutting off the summation in the partition function (9) has no effect on the thermodynamic functions to 4000 K. This is a result of the high energy of all levels other than the ground state and the levels listed above; the next excited state is approximately 20335 cm^{-1} above the ground state. Although we list only a few levels, all levels listed by Sugar and Corliss (8) and the estimated levels (for n < 80) are considered in the calculation. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of additional excited states and use of different fill and cutoff procedures (9).

The thermal functions at 298.15 K differ from the CODATA recommendations (1) for two reasons. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas CODATA recommendations are based on 1 atm. Second, small changes, ~0.002 J K^{-1} mol^{-1}, arise due to the use of slightly different values for the fundamental constants.

Enthalpy of Formation

$\Delta_f H°(Ca^+, g, 0\ K)$ is calculated from $\Delta_f H°(Ca, g, 0\ K)$ (1) using the spectroscopic value of IP(Ca) = 49305.96 ± 0.08 cm^{-1} (589.830 ± 0.001 kJ mol^{-1}) from Sugar and Corliss (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Ca^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Ca, g, 0\ K)$ by using IP(Ca) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Ca(g), Ca^+(g), and e^-(g). $\Delta_f H°(Ca \rightarrow Ca^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Sugar and Corliss (2), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (6) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is approximately 52167 cm^{-1} above the ground state. Since inclusion of these higher excited states have little effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (6).

Enthalpy of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among Ca, CaCl, and $CaCl_2$. Ion intensities were measured 2.5 eV above the ionization threshold. Using the equilibrium constants $K = I(CaCl^+)^2/I(Ca^+)I(CaCl_2^+)$ which we calculate from the reported ion intensities for the reaction $Ca(g) + CaCl_2(g) \rightarrow 2\ CaCl(g)$ in the temperature range 1252 – 1557 K, we obtain $\Delta_r H°(298.15\ K) = 15.81\ kcal\ mol^{-1}$ by the 3rd law method. The 3rd law drift is $-2.8 \pm 3.5\ cal\ K^{-1}\ mol^{-1}$. The enthalpy of formation is derived as $\Delta_f H°(CaCl, g, 298.15\ K) = -27.0\ kcal\ mol^{-1}$.

Zmbov (7) determined by mass spectrometry the enthalpy of the above reaction as $24.4 \pm 1.3\ kcal\ mol^{-1}$ with a drift of $12.5 \pm 9.4\ cal\ K^{-1}\ mol^{-1}$. This yields the enthalpy of formation, $\Delta_f H°(CaCl, g, 298.15\ K) = -22.7\ kcal\ mol^{-1}$.

Hildenbrand (2) also determined the equilibrium constants for the reaction (a) $Ca(g) + CaCl_2(g) \rightarrow 2\ CaCl(g)$ and the reaction (b) $Ca(g) + AlCl(g) \rightarrow CaCl(g) + Al(g)$ by mass spectrometry in the temperature range 1219-1353 K. 3rd law analysis of the reported equilibrium constants gives $\Delta_r H°(298.15\ K) = 21.08\ kcal\ mol^{-1}$ and drift $= -1.4 \pm 1.8\ cal\ K^{-1}\ mol^{-1}$ for reaction (a); and $\Delta_r H°(298.15\ K) = 24.20\ kcal\ mol^{-1}$ and drift $= 0.5 \pm 1.3\ cal\ K^{-1}\ mol^{-1}$ for reaction (b). From 3rd law $\Delta_r H°(298.15\ K)$ of (a) and (b), we derived $\Delta_f H°(CaCl, g, 298.15\ K) = -24.4$ and $-23.3\ kcal\ mol^{-1}$, respectively, using all JANAF functions. Hildenbrand has also derived a corrected $D_0^0(Ca\text{-}Cl) = 95.0\ kcal\ mol^{-1}$ from a linear Birge-Sponer extrapolation of the ground state vibrational levels with correction for its ionicity. This corrected $D_0^0(Ca\text{-}Cl)$ yields the enthalpy of formation, $\Delta_f H°(CaCl, g, 298.15\ K) = -23.9\ kcal\ mol^{-1}$.

Ryabova and Gurvich (3) reported $D_0^0(Ca\text{-}Cl) = 102 \pm 6\ kcal\ mol^{-1}$ from flame spectra studies. This leads to $\Delta_f H°(CaCl, g, 298.15\ K) = -30.9\ kcal\ mol^{-1}$.

Hildenbrand (6) determined the dissociation energy of $CaCl_2(g)$ by electron impact as $\Delta_{at} H°\ (CaCl\text{-}Cl) = 5.04 \pm 0.02\ kcal\ mol^{-1}$ which, combined with JANAF $\Delta_f H°(298.15\ K)$ of $CaCl_2(g)$ and Cl(g), gives $\Delta_f H°(CaCl, g, 298.15\ K) = -23.1\ kcal\ mol^{-1}$.

A weighted average, $\Delta_f H°(CaCl, g, 298.15\ K) = -25 \pm 3\ kcal\ mol^{-1}$ ($-104.6 \pm 13\ kJ\ mol^{-1}$) is adopted in the tabulation.

Heat Capacity and Entropy

The vibrational constants (ω_e and $\omega_e x_e$), electronic levels and ground state configuration were taken from Herzberg (4). Morgan and Barrow (5) made rotational analysis of the $C^2\Pi\text{-}X^2\Sigma$ system and reported $B_0 = 0.1516\ cm^{-1}$ and $r_e = 2.439$ Å for the ground state. The value of α_e is calculated from the Morse potential function. The F and G states were reported by Schutte (8).

PREVIOUS: June 1970 (1 atm) CURRENT: June 1970 (1 bar)

$S°(298.15\ K) = 104.6 \pm 4\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 1045\ K$

$\Delta_f H°(0\ K) = -796.3 \pm 1.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -795.8 \pm 1.3\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 28.543 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

Parker (1) has selected the standard enthalpy of formation at 298.15 K as -190.2 kcal mol^{-1} (-795.797 kJ mol^{-1}) which is adopted in the tabulation. The enthalpy of formation was derived from two independent paths. The first path involves $\Delta_f H°(Ca^{++}, aq, \infty, 298.15\ K) = -129.74$ kcal mol^{-1} (1), $\Delta_f H°(Cl^-, aq, \infty, 298.15\ K) = -39.952$ kcal mol^{-1} (2) and the enthaply of solution of $CaCl_2(cr)$ in water (3, 4, 5, 6, 7). The second path involves the enthalpies of reaction of Ca(cr), CaO(cr) and $CaCl_2(cr)$ in aqueous HCl solution (4, 8-20).

Heat Capacity and Entropy

Kelley and Moore (21) measured the low temperature heat capacities in the temperature range from 52.6 to 295.1 K and made an extrapolation to 0 K which yielded an entropy of 4.59±0.4 cal K^{-1} mol^{-1} at 50.12 K. We have adopted the measured heat capacities, but made our own extrapolation to 0 K by comparison with the measured heat capacities of $BaCl_2(cr)$ (22) and $SrCl_2(cr)$ (23) from 6 to 50 K. The extrapolation gives S°(50 K) = 2.45±1 cal K^{-1} mol^{-1}, which is used in the table. Moore (24) measured high temperature enthalpy data from 403.7 to 1667 K by drop calorimetry. The low temperature heat capacities and the heat capacities from the high temperature enthalpy data are smoothly joined at 298.15 K. The deviations of the observed enthalpies from the adopted values are about 2% near 400-500 K and only a few tenths percent at higher temperatures. Dworkin and Bredig (25) determined drop-calorimetrically H°(1045 K) -H°(298.15 K) = 14.3 kcal mol^{-1}, which is in very good agreement with the adopted value of 14.2 kcal mol^{-1}.

Fusion Data

The adopted melting point 1045 K was determined by Tokareva (26). Dworkin and Bredig (25) determined the enthalpy of fusion $\Delta_{fus}H°(1045\ K) = 6.78 \pm 0.1$ kcal mol^{-1} by drop calorimetry. Chiotti et al. (27) also measured the enthalpy of fusion $\Delta_{fus}H°(1055\ K) = 6.79 \pm 0.2$ kcal mol^{-1} in an adiabatic calorimeter. The adopted enthalpy of fusion, 6.822 kcal mol^{-1} (28.543 kJ mol^{-1}), is calculated from the difference between the observed relative enthalpy of the liquid and the adopted value for the crystal at the melting point.

Sublimation Data

The enthalpy of sublimation is calculated from the enthalpies of formation of $CaCl_2(cr)$ and $CaCl_2(g)$.

CALCIUM CHLORIDE ($CaCl_2$) LIQUID M_r = 110.986

$S°(298.15\ K)$ = [123.868] J K^{-1} mol^{-1}

T_{fus} = 1045 K

$\Delta_f H°(298.15\ K)$ = [-774.094] kJ mol^{-1}

$\Delta_{fus} H°$ = 28.543 ± 0.8 kJ mol^{-1}

Enthalpy of Formation

The enthalpy of formation is calculated from that of the crystal by adding the enthalpy of melting and the difference in enthalpy, H°(1045 K)-H°(298.15 K), between the crystal and the liquid.

Heat Capacity and Entropy

The constant heat capacity above the assumed glass transition at 700 K is derived from high temperature enthalpy data in a drop calorimeter from the melting point up to 1667 K by Moore (1). Below the glass transition point, the heat capacity is assumed to be the same as that of the crystal. Dworkin and Bredig (2) reported $C_p°(\ell)$ = 23.6 cal K^{-1} mol^{-1} from enthalpy measurements in a short temperature range by drop calorimetry.

S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

The boiling point, T_{vap}, is calculated as the temperature at which $\Delta_r G$ = 0 for $CaCl_2(\ell) \rightarrow CaCl_2(g)$ at one bar. The enthalpy of vaporization is the difference in $\Delta_f H°$ at T_{vap} between liquid and gas.

Bond Distance: Ca-Cl - 2.51 Å
Bond Angle: Cl-Ca-Cl = 180°
Rotational Constant: $B_0 = 0.037737\ cm^{-1}$

Enthalpy of Formation

2nd and 3rd law analyses of vapor pressure data are given below. The selected 3rd law enthalpy of vaporization is taken from Novikov's measurement (1) as $\Delta_{vap}H°(298.15\ K) = 72.30\ kcal\ mol^{-1}$ which is combined with $\Delta_f H°(298.15\ K)$ of the liquid to give $\Delta_f H°(CaCl_2, g, 298.15\ K) = -112.7 \pm 1\ kcal\ mol^{-1}$ ($-471.5 \pm 4\ kJ\ mol^{-1}$).

3rd law analyses indicate zero dirft for Novikov's data, positive and negative drifts for Hildenbrand's (2) and Bautista's (3) data, respectively. Their enthalpies are in good agreement within ±1 kcal. Wartenberg (4) reported there was no boiling at 1819 K at 62 mm Hg pressure, and his value, $\Delta_{vap}H°(298.15\ K) = 71.1 \pm 0.7\ kcal\ mol^{-1}$, serves as a guide for the minimum enthalpy of vaporization.

*Value in parentheses is the enthalpy of sublimation.

Heat Capacity and Entropy

The linear structure and vibrational frequencies were determined by White and co-workers (6) in the matrix-infrared-spectrometric studies. The linear structure is consistent with experimental error with the electric-quadrupole-deflection studies (7), and electron-diffraction data (8). Hayes (9) has qualitatively rationalized the linear structure through molecular orbital theory. The bond length was measured by Akishin and Spiridonov (8).

Enthalpy of Formation

Hastie and Margrave (1) have recently reviewed the dissociation energy of CaF and conclude that it is 127.5±2.5 kcal mol^{-1}. The analysis below considers basically the same data except that all values are JANAF.

Hildenbrand and Murad (2) in a mass spectrometric determination of the equilibria among BF, BF_3, Ca, CaF and CaF_2 reported equilibrium constants for the reaction

(A) $Ca(g) + CaF_2(g) \rightarrow 2CaF(g)$.

Blue et al. (3) have also examined several equilibria mass-spectrometrically and report equilibrium constants for reaction

(B) $Ca(g) + CaF_2(cr) \rightarrow 2CaF(g)$ and reaction

(C) $Ca(g) + AlF(g) \rightarrow Al(g) + CaF(g)$.

Ryabova and Gurvich (4) give a enthalpy of dissociation from flame studies for the reaction

(D) $CaF(g) \rightarrow Ca(g) + F(g)$.

The remaining reactions considered by Hastie and Margrave (1) were not included since they involved subtracting reactions not performed simultaneously, or involve species such as SiF_2 whose enthalpy of formation is dependent on that of CaF and CaF_2.

Source	T/K	Reaction	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Hildenbrand (2)	1583-1734	A	15	11.5±6.8	14.70±1.27	2.2±4.1	-65.5±1.8
Blue (3)	1271-1351	B	9	146.9±8.0	121.08±1.65	-19.4±6.2	-64.5±1.7
Blue (3)	1271-1351	C	10*	34.6±3.5	32.87±0.47	-1.4±2.7	-65.7±3.2
Ryobova (4)		D		135±7			-73.3±7
Hildenbrand (5)	1423-1443	A	2		32.97		-65.6±3.2

*1 point rejected due to failure of a statistical test

The auxiliary enthalpies of formation used were, in kcal mol^{-1}, AlF(g) = -63.4, Al(g) = 78, $CaF_2(g)$ = -187.5, $CaF_2(cr)$ = -293.0 and Ca(g) = 42.85.

We adopt a median value of $\Delta_f H°(CaF, g, 298.15\ K)$ = -65±2 kcal mol^{-1} (-271.960±8 kJ mol^{-1}) which corresponds to an enthalpy of dissociation of 126.7±2 kcal mol^{-1}.

Heat Capacity and Entropy

Herzberg (6) gives the vibrational constants and electronic levels. Harvey (7) has reported a value for B_0 which corresponds to a bond length of 2.02 Å. The Morse potential function was used to calculate α_e.
