PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

CALCIUM FLUORIDE (CaF_2) CRYSTAL M_r = 78.076806

$S°(298.15\ K) = 68.572 \pm 0.33\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 1424 \pm 20\ K\ (\alpha\text{-}\beta)$
$T_{fus} = 1691 \pm 5\ K$

$\Delta_f H°(0\ K) = -1223.0 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1225.9 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 4.770 \pm 0.4\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 29.706 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Torgeson and Sahama (1) measured the enthalpy of solution of CaO in aqueous 20.1% HF as -54.96 ± 0.02 kcal mol^{-1}. Using $\Delta_f H°(CaO, cr, 298.15\ K) = -151.79$ kcal mol^{-1} (2), $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.317$ kcal mol^{-1} (3) and $\Delta_f H°(HF \cdot 4.4H_2O, 298.15\ K) = -76.60$ kcal mol^{-1}, we obtain $\Delta_f H°(CaF_2, cr, 298.15\ K) = -291.6 \pm 0.6$ kcal mol^{-1}.

Smyshlyaev and Edeleva (5) report the solubility product of CaF_2 as $2.7 \pm 0.27 \times 10^{-11}$ in dilute HCl, which yields $\Delta G°(298.15\ K) = 14.42$ kcal mol^{-1} for the reaction $CaF_2(cr) \rightarrow Ca^{++}(aq, \infty) + 2F^-(aq, \infty)$. Using $\Delta_f G°(Ca^{++}, aq, \infty, 298.15\ K) = -132.30$ kcal mol^{-1} (2) and $\Delta_f G°(F^-, aq, \infty, 298.15\ K) = -66.95$ kcal mol^{-1} (4) we obtain $\Delta_f G°(CaF_2, cr, 298.15\ K) = -280.64 \pm 0.6$ kcal mol^{-1}, which, using the adopted functions, yields $\Delta_f H°(CaF_2, cr, 298.15\ K) = -293.1 \pm 0.6$ kcal mol^{-1}.

Vecher and Vecher (17) have measured the emf of a high temperature solid state cell and report $\Delta_r G°(1200) = -17.6 \pm 0.2$ kcal mol^{-1} for the reaction $CaO(cr) + MgF_2(cr) \rightarrow CaF_2(cr) + MgO(cr)$. This reduces to $\Delta_r H°(298.15\ K) = -17.6$ kcal mol^{-1}, using JANAF values for MgO and MgF_2 and CaO from reference 2, yields $\Delta_f H°(CaF_2, cr, 298.15\ K) = -294.4 \pm 1.3$ kcal mol^{-1}.

Kohlrauch (18) reported the solubility of CaF_2 and fluorspar, which yield solubility products of 3.6×10^{-11} and 2.8×10^{-11}. From these we obtain, as above, $\Delta_f H°(CaF_2, cr, 298.15\ K) = -292.9$ and -293.1 kcal mol^{-1}.

Guntz (19) made measurements on the neutralization of $Ca(OH)_2(aq)$ and HF(aq) which yield $\Delta_f H°(CaF_2, cr, 298.15\ K) = -293.1$ kcal mol^{-1}, according to Parker (2).

A median value of $\Delta_f H°(CaF_2, cr, 298.15\ K) = -293 \pm 1.5$ kcal mol^{-1} (-1225.912 ± 6.3 kJ mol^{-1}) is adopted.

Heat Capacity and Entropy

Huffman and Norwood (6) have measured the low temperature heat capacity in the range 3.6 to 30 K, Eucken and Schwers (7) in the range 17 to 86 K and Todd (8) from 54 to 296.5 K. We have fitted a smooth polynomial curve through the data of references 6 and 8 and this yields $S°(298.15\ K) = 16.38 \pm 0.08$ cal $K^{-1}\ mol^{-1}$ based on $S°(3.6\ K) = 0.0002$ cal $K^{-1}\ mol^{-1}$. The values of reference 7 deviate considerably at the lowest temperatures but are in reasonable agreement at higher temperatures.

The high temperature enthalpy of calcium fluoride has been reported by Naylor (9) to 1789 K, Krestnikov and Karetnikov (10) to 1273 K, and Lyashenko (11) to 1490 K. All the data are in approximate agreement and the more extensive results of Naylor on a very pure sample are adopted. The heat capacities, below 1424 K, were derived from a polynomial fit of the enthalpy data of the form $H = aT^2 + bT + c + d/T + e/T^2$.

Transition Data

The temperature of transition is that reported by Naylor (9), the large uncertainty has been assigned since at 1424 K the enthalpies indicate complete conversion to β-CaF_2, and the next lower point is at 1402 K. Evidence in support of a transition in this region comes from Lyashenko (11) whose plot indicates a break between 1273 and 1413 K. In addition, $SrCl_2$ which has the fluorite structure has a transition near the melting point. The enthalpy of transition is that reported by Naylor (9).

Fusion Data

McCreary (12) reports the melting point of a 99.1% pure sample as 1687 ± 5 K. Porter and Brown (13) report 1675 ± 5 K as the melting point of 99.8% pure CaF_2 and Rogers et al. (14) obtained 1684 K as the melting point. The adopted melting point, 1691 ± 5 K, for a sample of natural fluorite of high purity, was reported by Naylor (9). The enthalpy of melting, 7100 kcal mol^{-1} (29.706 kJ mol^{-1}), is that measured by Naylor (9). Three determinations from high temperature phase diagrams give 7250 ± 350 cal mol^{-1} (15), 5500 cal mol^{-1} (16) and 9800 cal mol^{-1} (14).

Sublimation Data

See the ideal gas table for details.

Calcium Fluoride (CaF_2) $Ca_1F_2(cr)$

CALCIUM FLUORIDE (CaF_2) LIQUID M_r = 78.076806

$S°(298.15\ K) = [92.573]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1691 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-1186.067]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 29.706 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(CaF_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1691\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived from the enthalpy measurements of Naylor (1). The heat capacity is constant in the real liquid range but at 1000 K a glass transition is assumed below which it follows that of the crystal. The entropy is calculated in a manner analogous to that used for the enthalpy of formation

Fusion Data

See the crystal table for details.

Vaporization data

The boiling point, T_{vap}, is calculated as the temperature at which the fugacity of $CaF_2(g)$ is one bar for the process $CaF_2(\ell) = CaF_2(g)$. The enthalpy of vaporization is the difference in $\Delta_f H°$ at T_{vap} between the liquid and gas.

$S°(298.15\ K) = 273.80 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -782.6 \pm 8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -784.5 \pm 8\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
484 (1)
163 (1)
554 (1)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distance: Ca-F = 2.1 Å

Bond Angle: F-Ca-F = 135 ± 7°

Product of the Moments of Inertia: $I_A I_B I_C = 1.283897 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation is obtained from that of the crystal by adding $\Delta_{sub}H°(298.15\ K)$. The vapor pressure data of five authors are analyzed by 2nd and 3rd law methods to give $\Delta_{sub}H°(298.15\ K)$ as listed below. Note that the drifts are small and both positive and negative confirming the correctness of the functions used.

Reference	T/K	Data Points	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}
Freeman (1)	1463-1668	9	106.2±3.7	105.66±0.9	-0.2±2.3
Blue et al. (2)	1246-1498	6	99.6±2.5	106.00±1.0	4.1±2.0
Schulz and Searcy (3)	1421-1689	34	102.4±0.3	104.00±0.2	1.0±0.2
Pottie (4)	1823	1		106.4	
Ruff and LeBoucher (5)	2086-2208	7	106.7±4.8	105.22±0.5	-0.7±2.2
Blue et al. (2)*	1242-1669	19	104.7±0.5		

*This set was not analyzed by the 3rd law since the absolute pressures were adjusted by the authors to match their weight loss values.

A median value of 105.5±0.5 kcal mol^{-1} (441.412±2.1 kJ mol^{-1}) is adopted for the enthalpy of sublimation which yields $\Delta_f H°(CaF_2, g, 298.15\ K) = -187.5 \pm 2$ kcal mol^{-1} (-784.5 ± 8 kJ mol^{-1}).

Heat Capacity and Entropy

The bond length was measured by Aksihin and Spiridonov (6), but the diffraction patterns were interpreted as indicating a linear molecule. The vibrational frequencies and bond angle are those reported by Calder (7) using matrix isolation spectroscopy and isotopically enriched materials.

The principal moments of inertia are: $I_A = 2.0918 \times 10^{-39}$, $I_B = 23.7505 \times 10^{-39}$, and $I_C = 25.8423 \times 10^{-39}\ g\ cm^2$.

Point Group: $[C_{\infty v}]$ $\sigma = 1$
Bond Distance: Ca-O = [2.03] Å O-H = [0.96] Å
Bond Angle: Ca-O-H = [180]°
Rotational Constant: B_0 = [0.318811] cm^{-1}

Enthalpy of Formation

The adopted $\Delta_f H°(CaOH, g, 0\ K) = -45.41 \pm 5\ kcal\ mol^{-1}$ ($-190.0 \pm 21\ kJ\ mol^{-1}$) is based on an assessment of D_0^0 values derived from flame spectra of CaOH, SrOH, and BaOH. Cotton and Jenkins (1) found both the monohydroxides and dihydroxides of the alkaline earths to be present in significant amounts in fuel-rich hydrogen-oxygen-nitrogen flames. They determined equilibrium constants for the reactions $M(g) + H_2O(g) = MOH(g) + H(g)$ and $M(g) + 2\ H_2O(g) = M(OH)_2(g) + 2\ H(g)$ and derived D_0^0 values. In earlier work, Ryabova and Gurvich (2) had considered CaOH to be the dominant compound, and Sugden and Schofield (3) had interpreted $Ca(OH)_2$ as dominant. Cotton and Jenkins (1) have recalculated the work of these last two investigations, considering both CaOH and $Ca(OH)_2$ to be present. Ryabova et al. (4) and Kalff and Alkemade (5) have made additional measurements.

	D_0^0, kcal mol^{-1} $CaOH(g) = Ca(g) + OH(g)$		
Reference	As Published	As Recalculated by Cotton and Jenkins (1)	As Corrected for Current JANAF Auxiliary Data (6)
Ryabova and Gurvich (2)	100±8	99	
Sugden and Schofield (3)		102	
Cotton and Jenkins (1)	104±5		105.5
Ryabova et al. (4)	94±3		97.5[a]
Kalff and Alkemade (5)	102.4		

[a]An approximate correction of +3.5 kcal mol^{-1} is made, 2 kcal mol^{-1} assumed from the Cotton and Jekins' type calculation for the presence of both CaOH and $Ca(OH)_2$ and 1.5 kcal mol^{-1} indicated by the recalculation of Cotton and Jenkins' work (1) using auxiliary data from the current JANAF Tables (6).

The data analyses for $BaOH(g)$ and $Ba(OH)_2(g)$ indicate that flame-spectral data tend to give high dissociation energies. For $Ca(OH)_2(g)$, the lowest value of D_0^0(HO-Ca-OH) was adopted (6). Similarly, D_0^0(Ca-OH) = 97.5 kcal mol^{-1} is adopted.

The ratio of the dissociation energies of the alkaline earth monohalides to those of the corresponding dihalides range from 0.40 to 0.51 with the ratio for the calcium fluorides being 0.47 (6). The similarity between the halides and hydroxides has been established (7-10). The ratio of the adopted values for the dissociation energies of CaOH(g) and $Ca(OH)_2(g)$ is 0.47 where D_0^0 of the dihydroxide is defined by the reaction $Ca(OH)_2 = Ca(g) + 2(OH)(g)$ and is 205.6 kcal mol^{-1}.

Heat Capacity and Entropy

The analogy between gaseous monohydroxides and monohalides, particularly the monofluorides, has been recognized (7-10). The molecular configuration is assumed to be linear in accordance with the prediction of Walsh (11) and the evidence that gaseous alkali metal hydroxides are linear (12-14). The ground state is assumed to be $^2\Sigma^+$ by analogy with CaF and CaCl (6). The electronic levels are estimated from the band spectra observed by James and Sugden (15), Gaydon (16), Zhitkevich et al. (17) and van der Hurk et al. (18), and the comparison with CaF and CaCl (6).

The Ca-O bond distance is estimated to be slightly larger, 0.02 Å, than the Ca-F distance (6) after noting the close similarity in bond distance of the alkali metal fluorides and hydroxides. The O-H bond distance is that in water (6).

The Ca-O stretching frequency, 587 cm^{-1}, is estimated to be the same as the CaF stretching frequency (6, 10). The O-H stretching frequency, 3650 cm^{-1}, is estimated from the alkali hydroxide series. The bending frequency, 466 cm^{-1}, is estimated by assuming that the ratio of the bending force constant to the stretching force constant is 0.022, which is the average ratio found in the alkali metal monohydroxides by Acquista and Abramowitz (10, 14).

The entropy in the present table is lower by 0.20 cal $K^{-1}\ mol^{-1}$ at 298.15 K and 0.25 cal $K^{-1}\ mol^{-1}$ at 1000 K than that proposed by Jackson (10); the data relevant to the calculations are nearly the same.

[3650](1)

Ground State Quantum Weight = [1] σ = 1

Point Group: [$C_{\infty v}$]

Bond Distances: Ca-O = [2.03] Å O-H = [0.96] Å

Bond Angle: Ca-O-H = [180°]

Rotational Constant: B_0 = [0.318830] cm^{-1}

Enthalpy of Formation

The ionization potential of CaOH(g) was deduced by Kelly and Padley (1) to be 5.9±0.1 eV. These authors quantitatively examined the total positive ion concentrations produced from Ca aqueous salt additives in fuel rich, premixed $H_2 + O_2 + N_2$ flames. Using current JANAF auxiliary data (2), we recalculate the ionization potential to be 5.79 eV.

Jensen (3) determined the enthalpy of reaction $\Delta_r H°(0\ K)$ = 35±10 kcal mol^{-1} for Ca(g) + OH(g) = $CaOH^+$(g) + e^- in atmospheric pressure $H_2 + O_2 + N_2$ flames using the microwave cavity resonance method. This value was calculated assuming a bent molecule for $CaOH^+$; the value is not significantly changed, within the uncertainty, by the change in the configuration. Using auxiliary data (2), we derive an ionization potential of 5.75 eV, which is in good agreement with the value derived from the data of Kelly and Padley (1).

We adopt an ionization potential of 5.77 eV (133.06 kcal mol^{-1}) which is average of the above two studies (1, 3). This leads to $\Delta_f H°(0\ K)$ = 87.651 kcal mol^{-1} and $\Delta_f H°(298.15\ K)$ = 88.213 kcal mol^{-1} (369.08 kJ mol^{-1}) for $CaOH^+$(g). We assign an uncertainty of ±15 kcal mol^{-1}.

For comparison, the appearance potential of CaF(g) has been reported as 5.8±0.3 eV (4), 5.5±0.3 eV (4) and 6.0±0.5 eV (5). These values are all very similar to the ionization potential adopted here for CaOH(g). In addition, the ionization potential for Ca(g) is 6.11 eV (2).

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that the gaseous alkali metal hydroxides are linear (2, 6, 7, 8). In addition, Walsh (9) had predicted that triatomic molecules (containing hydrogen) with ten or less valence electrons ($CaOH^+$ has eight valence electrons) will be linear in their ground state. The molecule $CaOH^+$ is isoelectronic with KOH.

The bond dissociation energy for $CaOH^+$ (D_0^0 =105.4 kcal mol^{-1}, 2) for the process $CaOH^+$(g) = Ca^+(g) + OH(g) is fairly close to that for CaOH (D_0^0 = 97.5 kcal mol^{-1}, 2). This suggests a similar bonding in these two molecules. Thus, bond distances are assumed to be the same as those adopted for CaOH(g, 2). The ground state quantum weight is assumed to be the same as that of KOH(g, 2).

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

CALCIUM HYDROXIDE ($Ca(OH)_2$) CRYSTAL M_r = 74.09468

$S°(298.15\ K) = 83.387 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -977.36 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -986.09 \pm 1.3\ kJ\ mol^{-1}$

Enthalpy of Formation

Taylor and Wells (1) measured enthalpies of solution of $Ca(OH)_2$(cr) and CaO(cr) in dilute HCl and obtained $\Delta_r H°(298.15\ K)$ = -15.58 ± 0.1 kcal mol^{-1} for CaO(cr) + $H_2O(\ell)$ = $Ca(OH)_2$(cr) which leads to $\Delta_f H°(Ca(OH)_2, cr, 298.15\ K) = -235.68 \pm 0.3$ kcal mol^{-1} using $\Delta_f H°(CaO, cr, 298.15\ K) = -151.79 \pm 0.21$ kcal mol^{-1} (2) and $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.315$ kcal mol^{-1} (3). This value, -235.68 ± 0.3 kcal mol^{-1} (-986.09 kJ mol^{-1}) is adopted in the tabulation. They also measured directly the enthalpy of hydration of CaO to $Ca(OH)_2$ and found $\Delta_r H°(298.15\ K) = -15.43 \pm 0.1$ kcal mol^{-1} which leads to $\Delta_f H°(Ca(OH)_2, cr, 298.15\ K) = -235.53$ kcal mol^{-1}. Both measurements are in very good agreement. Literature $\Delta_r H°$ data (4, 5, 6, 7, 8) determined by these two methods were within the limit of -15.40 ± 0.3 kcal mol^{-1} which is in good agreement with the value adopted.

JANAF analyses of dissociation pressure data (9, 10, 11) for $Ca(OH)_2$(cr) + CaO(cr) + H_2O(g) are listed below. The data of Halstead and Moore (9) and of Tamaru and Shiomi (10) are in good agreement, but the pressures reported by Johnston (11) are too low due to failure to reach equilibrium. The enthalpy of formation derived from 3rd law $\Delta_r H$ of Halstead and Moore (9) or Tamaru and Shiomi (10) is in good agreement with the value adopted. However, the decomposition of $Ca(OH)_2$ *may yield non-standard state* CaO in the final product which was shown in a similar decomposition of $Mg(OH)_2$. See $Mg(OH)_2$ table (2) for details.

$Ca(OH)_2(cr) = CaO(cr) + H_2O(g)$

Heat Capacity and Entropy

The low temperature heat capacities up to 300 K are taken from the adiabatic calorimeter measurements (19-330 K) of Hatton et *al.* (12). Above 300 K, the heat capacities are based on the heat conduction calorimeter measurements (310-670 K) of Kobayashi (13) joined smoothly at 300 K with the low temperature heat capacities (12) and on a graphical comparison of the Cp vs T curve adopted for $Mg(OH)_2$(cr)(2). The entropy, $S°(298.15\ K) = 19.93 \pm 0.1$ cal K^{-1} mol^{-1} (83.387 ± 0.4 J K^{-1} mol^{-1}), is derived from the adopted low temperature heat capacities, based on a T^3 extrapolation to obtain $S° = 0.070$ cal K^{-1} mol^{-1} at 20 K (12).

Decomposition Data

T_{dcm} is calculated as the temperature at which $\Delta_r G° = 0$ for the reaction $Ca(OH)_2$(cr) = CaO(cr) + H_2O(g). Auxiliary data are from the JANAF Tables (2).

Under a pressure of 1000 bars, Wyllie and Tuttle (14) found that $Ca(OH)_2$ melts congruently at 1108 K.

Enthalpy of Formation

Dissociation energies, D_0^0, for the reaction $Ca(OH)_2(g) = Ca(g) + 2\ OH(g)$ have been derived from flame-spectral measurements (1-3). Ryabova and Gurvich (1) believed the dominant reaction to be $Ca(g) + H_2O(g) = CaOH(g) + H(g)$, but they also considered the possibility that $Ca(g) + 2\ H_2O(g) = Ca(OH)_2(g) + 2\ H(g)$ was the dominant reaction and derived D_0^0 = 200±20 kcal mol^{-1}. Sugden and Schofield (2) considered the dihydroxide to be the dominant product and derived D_0^0 = 217±12 kcal mol^{-1}. Cotton and Jenkins (3) found both CaOH and $Ca(OH)_2$ to be present in significant amounts in fuel-rich hydrogen-oxygen-nitrogen flames and derived D_0^0 = 203.8±5 kcal mol^{-1}. Cotton and Jenkins (3) recalculated the work of Ryabova and Gurvich (1) and Sugden and Schofield (2) considering both CaOH and $Ca(OH)_2$ to be present and obtained the recalculated D_0^0 values of 199 and 201 kcal mol^{-1}, respectively.

A 3rd law analysis of the experimental equilibrium constants tabulated by Cotton and Jenkins (3) using current JANAF auxiliary data (4) leads to D_0^0 = 210.4 kcal mol^{-1} which is 6.6 kcal mol^{-1} higher than the 203.8 kcal mol^{-1} derived by Cotton and Jenkins (3). Applying this difference to the data of Ryabova and Gurvich (1) and Sugden and Schofield (2) as recalculated by Cotton and Jenkins (3) gives D_0^0 = 205.6 and 207.6 kcal mol^{-1}, respectively.

For $Ba(OH)_2(g)$ (4), the corrected dissociation energy of Ryabova and Gurvich (4), D_0^0 = 208.8 kcal mol^{-1}, is in better *agreement with the "adopted" value of 209.6 kcal* mol^{-1}, *based on good Knudsen-cell mass-spectrometric measurements, than are the* corrected dissociation energies of Sugden and Schofield or Cotton and Jenkins (4). We adopt D_0^0 = 205.6 kcal mol^{-1} for the dissociation of $Ca(OH)_2$ from which is calculated $\Delta_f H°(0\ K)$ = -144.16±9 kcal mol^{-1} (-603.165±37.7 kJ mol^{-1}).

The enthalpy of dissociaton listed by Jackson (8) leads to $\Delta_f H°(Ca(OH)_2, g, 298.15\ K)$ = -142.65 kcal mol^{-1}. Another recent compilation (9) lists $\Delta_f H°(298.15\ K)$ = -130 kcal mol^{-1}.

Heat Capacity and Entropy

The analogy between gaseous mono- and dihydroxides and gaseous mono- and dihalides, particularly the mono- and difluorides, has been recognized (5-8). The O-Ca-O bond angle is assumed to be the same as the F-Ca-F bond angle (4); the Ca-O-H bond angle is considered to be linear as in CaOH (4). The Ca-O bond distance is estimated to be slightly larger, 0.02Å, than the Ca-F bond distance in CaF_2 (4) after noting the close similarity in the bond distance of alkali metal fluorides and hydroxides. The O-H bond distance is taken to be the same as in water (4).

The vibrational frequencies are estimated to be the same as in CaF_2 (4) (O-Ca-O symmetrical and asymmetrical stretch, and bend) and as in CaOH (4), (O-H stretch and Ca-O-H bend). The principal moments of inertia are $I_A = 2.1629 \times 10^{-39}$ g cm^2, $I_B = 23.0947 \times 10^{-39}$, and $I_C = 25.2576 \times 10^{-39}$.

Jackson (8) has used a different molecular configuration and different vibrational frequencies to estimate S°(298.15 K) = 68.530 cal K^{-1} mol^{-1}(1 atm). We assign an uncertainty of ±2.0 cal K^{-1} mol^{-1} to the adopted entropy.

Enthalpy of Formation

The adopted $\Delta_f H°(0\ K) = -0.65 \pm 20\ kcal\ mol^{-1}$ is calculated from the $D_0^0 = 3 \pm 1\ eV(69 \pm 23\ kcal\ mol^{-1})$ selected by Gaydon (1). A linear Birge-Sponer extrapolation of ω_e and $\omega_e x_e$ data (2) with a correction for the ionic character of the molecule as described by Hildenbrand (3) gave $D_0^0 = 66.5\ kcal\ mol^{-1}$. Other D_0^0 values are 63.9 kcal mol^{-1} (4) as a lower bound from a consideration of ionic bonding forces and 64 kcal mol^{-1} (5) derived as a lower bound from a consideration of energy conservation and measured reaction threshold relative kinetic energy from crossed molecular beam experiments. Of the four ratios, $D_0^0(CaI)/\Delta_{at}H°(CaI_2)$, $D_0^0(CaI) = 69\ kcal\ mol^{-1}$ gives 0.445 which is closest to 0.46 found for a series of mono- and difluorides (6) and for other alkaline earth halide systems (8). $\Delta_f H°(298.15\ K) = -1.21 \pm 20\ kcal\ mol^{-1}$ is calculated from the adopted $\Delta_f H°(0\ K) = -0.65 \pm 20\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The ground state vibrational constants are from the compilation of Rosen (2). The value of $r_e = 2.88$ Å is assumed the same as the bond distance in CaI_2 (7). B_e is calculated from the adopted r_e. α_e is calculted assuming a Morse potential function.

The electronic levels and their probable designation are those given by Rosen (2).

PREVIOUS: June 1974 (1 atm) CURRENT: June 1974 (1 bar)

$S°(298.15\ K) = 145.29 \pm 0.21\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 1052 \pm 2\ K$

$\Delta_f H°(0\ K) = -535.8 \pm 2.1\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -536.8 \pm 2.1\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 41.84 \pm 0.84\ kJ\ mol^{-1}$

Enthalpy of Formation

Ehrlich, Peik and Koch (1) derived $\Delta_f H°(CaI_2, cr, 298.15\ K) = -128.1 \pm 0.4$ kcal mol^{-1} from enthalpy of solution measurements of Ca(cr) and CaI_2(cr) in 0.1 N HI. An auxiliary HI enthalpy of solution value, -13.22 kcal mol^{-1}, calculated from data in reference (2) was used in the derivation. This auxiliary value will be changed by incorporation of the accepted CODATA value of $\Delta_f H°(I^-, aq, std.\ state, 298.15\ K) = -13.60$ kcal mol^{-1} (3) in the $\Delta_f H°$(HI, aq solution, 298.15 K) table, so that the above derived enthalpy of formation of CaI_2(cr) will be approximately -128.6 kcal mol^{-1}.

Combining $\Delta_f H°(Ca^{+2}, aq, std.\ state, 298.15\ K) = -129.74$ kcal mol^{-1}, selected by Parker (4, 5) with the CODATA value for I^-(aq, std. state) (3) gives $\Delta_f H°(CaI_2, aq, std.\ state, 298.15\ K) = -156.94$ kcal mol^{-1}. Further combination with the enthalpy of solution, -28.62 kcal mol^{-1} (5, 6) gives $\Delta_f H°(CaI_2, cr, 298.15\ K) = -128.32$ kcal mol^{-1}. This enthalpy of solution value was based on several sets of data, one of which was that of Ehrlich, et al. (1, 6).

We adopt -128.3 ± 0.5 kcal mol^{-1} (-536.807 kJ mol^{-1}) because of the correlation of $\Delta_f H°(Ca^{+2}, aq, std.\ state, 298.15\ K)$ with the evaluation of data for several calcium compounds (4).

Heat Capacity and Entropy

Paukov, Khriplovich, and Korotkikh (7) have measured $C_p°$ (13.10 - 309.18 K). Our T^3 extrapolation is in agreement with their values of S°(13 K) = 0.516 cal K^{-1} mol^{-1} and H°(13 K) - H°(0 K) = 4.99 cal K^{-1} mol^{-1}. The low temperature heat capacity joins smoothly with a linear extrapolation from $C_p°$ = 18.31 cal K^{-1} mol^{-1} at 270 K to $C_p°$ = 22.0 cal K^{-1} mol^{-1} at the adopted T_{fus} = 1052 K. The linearly extrapolated heat capacity at 300 K is only 0.3% higher than the Paukov et al. (7) value and S°(298.15 K) = 34.72 cal K^{-1}mol^{-1} is in agreement with Paukov et al. (7). Dworkin and Bredig (8) determined the heat capacity of the crystal to be 23.2 cal K^{-1} mol^{-1} (± 5%) near the melting point. By using the lower limit, $C_p°$ = 22.0 cal K^{-1} mol^{-1} of Dworkin and Bredig's value (8), H°(1052 K) - H°(298.15 K) is brought down to 15.24 kcal mol^{-1}, about 0.7% higher than Dworkin and Bredig's drop calorimeter measurement of 15.1 (± 0.2%) kcal mol^{-1} (8).

Fusion Data

Dworkin and Bredig (8) measured $\Delta_{fus}H°$ = 10.00 kcal mol^{-1} (± 2%) at T_{fus} = 1052 K ($S°_{fus}$ = 9.5 cal K^{-1} mol^{-1}) by drop calorimetry. Emons and Loeffelholz (9) determined $\Delta_{fus}H°$ = 6.65 kcal mol^{-1} (± 5%) and T_{fus} = 1053 K ($\Delta_{fus}S°$ = 6.3 cal K^{-1} mol^{-1}) by high temperature cryoscopy. The two pair of investigators are in much better agreement with other salts (9). An entropy of melting criteria for choosing one of these values is not conclusive because the entropies of melting of CdI_2, $CdCl_2$, and $CdBr_2$ which have similar layer crystal structure range from 7.5 to 9.5 cal K^{-1} mol^{-1} (10). Hutchison (11) found T_{fus} = 1018 K, noting that only approximate melting points were obtained.

Because drop calorimetry is a more direct measure of the enthalpy of melting, we adopt $\Delta_{fus}H°$ = 10.00 ± 0.20 kcal mol^{-1} at T_{fus} = 1052 ± 2 K.

Although unconfirmed by direct experimental evidence, the discrepancy in enthalpy of melting and the adjustments required in joining low temperature and high temperature heat capacities might be explained by the existence of a solid state transition in CaI_2 similar to the transitions in $BaCl_2$, $SrBr_2$, or $SrCl_2$ (8).

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ is calculated as the difference between the enthalpies of formation at 298.15 K of the ideal gas and crystal states.

CALCIUM IODIDE (CaI_2) LIQUID M_r = 293.8890

$S°(298.15\ K) = [178.942]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1052 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-500.170]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 41.84 \pm 0.84\ kJ\ mol$

Enthalpy of Formation

$\Delta_f H°(CaI_2, \ell, 298.15\ K)$ is calculated from the sum of the enthalpy of formation of the crystal, the enthalpy of melting, and the difference in enthalpy, H°(1052 K) -H°(298.15 K), between the crystal and the liquid.

Heat Capacity and Entropy

The liquid heat capacity near the melting point, 24.7 cal K^{-1} mol^{-1}, was derived by Dworkin and Bredig (1) from drop calorimetric measurements. This value is adopted and is assumed constant from 700 K to 2500 K. A glass transition is assumed at 700 K below which the heat capacity is that of the crystal.

$S°(CaI_2, \ell, 298.15\ K)$ is calculated from the crystal entropy in a manner similar to that used for the enthalpy of formation calculation.

Vaporization Data

The temperature at which $\Delta_r G° = 0$ for the reaction $CaI_2(\ell) = CaI_2(g)$ at one bar is T_{vap}. Peterson and Hutchison (2) have extrapolated Knudsen effusion cell measurements in the 1076 - 1294 K range to obtain a normal boiling point of 1831 K (at 1 atm).

$\Delta_{vap} H°$ is the calculated difference between the enthalpies of formation of the ideal gas and the liquid at T_{vap}. See the ideal gas table for details.

Calcium Iodide (CaI_2) Ca_1I_2(cr,l)

CALCIUM IODIDE (CaI_2) IDEAL GAS M_r = 293.8890

$S°(298.15\ K) = [327.57 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -255.2 \pm 17\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -258.2 \pm 17\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[117](1)
[45](2)
[316](1)

Ground State Quantum Weight = [1] $\sigma = 2$
Point Group: $D_{\infty h}$
Bond Distance: Ca-I = 2.88 ± 0.03 Å
Bond Angle: I-Ca-I = [180°]
Rotational Constant: B_0 = 0.008008 cm^{-1}

Enthalpy of Formation

Peterson and Hutchison (1) used a weight loss Knudsen effusion technique to observe vapor pressures of the liquid at 18 temperatures ranging from 1076 K to 1294 K. Our 2nd and 3rd law analyses of these data, after rejection of one point due to failure of a statistical test, yield $\Delta_{vap}H°(298.15\ K)$ (2nd Law) = 60.83 ± 2.04 kcal mol^{-1} and $\Delta_{vap}H°(298.15\ K)$ (3rd Law) = 57.84 ± 0.98 kcal mol^{-1} with a drift of −2.6 ± 1.7 cal K^{-1} mol^{-1}. We adopt $\Delta_{vap}H°(298.15\ K)$ = 57.8 ± 3 kcal mol^{-1} and combine that with the adopted enthalpy of formation of the liquid to obtain $\Delta_f H°(CaI_2, g, 298.15\ K)$ = −61.7 ± 4 kcal mol^{-1} (−258.153 ± 17 kJ mol^{-1}).

Heat Capacity and Entropy

The bond distance, as determined from an electron diffraction study, is taken from Akishin et al. (3) who also judged that the bond angle was 180° ± 10-20°. We have assumed a linear structure.

To estimate the vibrational frequencies, the stretching force constants for gaseous CaF, CaF_2, CaCl, and $CaCl_2$ are calculated from the vibrational frequencies (4) using a valence force model. The trend in the ratio of k(monohalide)/k_1(dihalide) indicates that $k(CaI)/k_1(CaI_2) = 1$ is a reasonable approximation, an approximation which has been used by Brewer et al. (5). The stretching force constant for CaI(g) is calculated from the ground state vibrational frequency given by Rosen (6). The bending force constant is assumed to be 0.01 times the stretching force constant (5). The adopted vibrational frequencies are calculated from the estimated force constants. Other estimates for ν_1, ν_2, and ν_3 are 121, 77, 327 (7) and 118, 45, 321 (5).

We assign an uncertainty of ±2 cal K^{-1} mol^{-1} to the entropy to allow for error in bond angle and vibrational frequency estimates.

PREVIOUS: June 1974 (1 atm) CURRENT: June 1974 (1 bar)

$S°(298.15\ K) = 38.212 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3200 \pm 50\ K$

$\Delta_f H°(0\ K) = -631.76 \pm 0.88\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -635.09 \pm 0.88\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [79.5]\ kJ\ mol^{-1}$

Enthalpy of Formation

Huber and Holley (1) determined the enthalpy of combustion of calcium metal in a bomb calorimeter and derived the enthalpy of formation of calcium oxide (cr) as -151.9 kcal mol^{-1} which is adopted in the tabulation. The adopted value is in good agreement with the value, -151.9 kcal mol^{-1} (2) derived from solution calorimetry.

Heat Capacity and Entropy

Gmelin (3) measured low temperature Cp data from 4 to 300 K in an adiabatic calorimeter. We use his smoothed Cp values to derive $S°(298.15\ K) = 9.133 \pm 0.03$ cal K^{-1} mol^{-1} based on $S° = 0.0001$ cal K^{-1} mol^{-1} at 4 K. Lander (4) determined high temperature enthalpy data from 563.6 to 1176.4 K by drop calorimetry. The low temperature Cp and high temperature enthalpy data are smoothly joined at 298.15 K by a polynomial curve fitting method. The deviations of the observed enthalpies from the adopted values are about 0.2-1%, except the enthalpy value at 753 K (2.0%). Heat capacities above 1200 K are extrapolated from the adopted Cp functions. The extrapolated Cp at the melting point (2887 K), 14.8 J K mol^{-1}, is in reasonable agreement with the value 2 x 7.25 cal K^{-1} g-$atom^{-1}$ suggested by Kubaschewski (5).

Combination of the earlier low temperature Cp measurements of Nernst and Schwers (28-90 K) (6) and Parks and Kelley (87-293 K) (7) yields $S°(298.15\ K) = 9.5 \pm 0.2$ cal K^{-1} mol^{-1}, based on $S°(298.15\ K) = 0.04$ cal K^{-1} mol^{-1} (8). These Cp measurements are less accurate than those of Gmelin (3), and are not adopted in the tabulation.

Fischer and Ertmer (9) determined high temperature enthalpy data by drop calorimetry in the temperature range from 0° to 1716°C. The accuracy was claimed to be approximately ±4%. We have not adopted their enthalpy data in the tabulation since the heat capacities which we derive from their data are always less than those of MgO (10) when the temperature is above 1000 K. The deviations between their enthalpy data and the adopted values are approximately 1.8% at 693 K, 3.3% at 1283 K and 5.3% at 1989 K.

Fusion Data

Schneider (11) adjusted earlier melting points (12-15) to IPTS-48, yielding values ranging from 2565° to 2630°C. Recent studies by Foex (16, 17), using solar energy to melt the center of a rotating crucible of oxide, gave values higher by about 300°C. Apparently the earlier values were depressed by formation of tungstates with the tungsten supports of the sample. Unfortunately, Foex reported three values: 2910°C (16, 1968), 2950°C(16, 1968) and 2900°C (17, 1969). We adopt an intermediate value of 2927°C = 3200 K and arbitrarily assign an uncertainty of 50 K.

The enthalpy of melting is assumed to be 19 kcal mol^{-1} which is calculated from the estimated $\Delta_{fus} S° \approx 6$ cal K^{-1} mol^{-1} at the melting point. The latter is estimated to be the same as that of MgO (10).

PREVIOUS: June 1971 CURRENT: June 1973

CALCIUM OXIDE (CaO) LIQUID M_r = 56.0794

$S°(298.15\ K) = [62.321]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3200 \pm 50\ K$

$\Delta_f H°(298.15\ K) = [-557.335]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [79.5]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus}H$ and the difference in enthalpy, $H°(3200\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2100 K. Heat capacities of the liquid below 2100 K are assumed to be the same as those of the crystal. Above 2100 K the heat capacity is assumed to be constant at 7.50 cal K^{-1} g-atom^{-1}.

The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Decomposition

CaO does not vaporize simply to CaO(g); extensive dissociation of CaO(g) to Ca(g) was found mass-spectrometrically (1).

Enthalpy of Formation

We adopt D_0^0 = 91 ± 5 and $\Delta_f H°(298.15\ K)$ = 10.5 ± 5 kcal mol^{-1} based on mass-spectrometric data (8, 9) for four reactions analyzed below. We give "<" or ">" for $\Delta H°$ and D_0^0 values which may be biased due to our auxiliary data. JANAF differences in $\Delta_f H°(298.15\ K)$ for WO_3-WO_2 and MoO_3-MoO_2 (5) may be biased by up to -3.5 and +4.1 kcal mol^{-1}, respectively, leading to bias of the opposite sign in D_0^0 values derived from reactions B and C. Adjustments for this possible bias would improve the agreement in D_0^0 but leave the mean value almost unchanged. Kalff (10) used spectrometry of CO-N_2O flames to derive D_0^0 = 86.5 ± 4.6 kcal mol^{-1}. This value becomes ~89.5 kcal mol^{-1} when adjusted to be consistent with JANAF Gibbs energy functions. Our adopted D_0^0 = 91 ± 5 is similar to that of Rosen (6) and is comparable with other selected values (8, 11), considering the difference in CaO functions.

The controversy over D_0^0 of alkaline earth oxides has been reviewed in detail (8, 11-13). Uncertainty in the electronic partition function of CaO due to triplet states now is much reduced (1). Schofields's criticism (12) of flame studies is supported by new evidence for importance of hydroxides (10, 14, 15); thus, we dismiss higher flame values for D_0^0 (12). Valid criticism (8) also causes us to dismiss higher D_0^0 values derived from vaporization data. A linear Birge-Sponer extrapolation yields a very low estimate for D_0^0, just as it does for the alkali halides (13), unless $X^1\Sigma$ fails to dissociate to an excited state atom as predicted (17, 1).

Source	Method	Reaction[a]	T/K	Data Points	δS cal $K^{-1}mol^{-1}$	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	kcal/mol $\Delta_f H°(298.15\ K)$	D_0^0
(8)	Knudsen mass spec.	A	2168-2410	4	-2.3±9.7	24±22	29.4±3	12.7	88.8
	Knudsen mass spec.	B	2328-2334	2	67	209	51.9±3	>6.5	<95.0
	Knudsen mass spec.	C	2393-2410	3	12±83	85±100	55.8±3	<15.5	<85.9
(9)	Knudsen mass spec.	D	2180-2386	3	1±31	31±72	27.9±6	5.6	95.8[b]

[a]Reactions: A) $Ca(g) + O_2(g) = CaO(g) + O(g)$; C) $Ca(g) + MoO_3(g) = CaO(g) + MoO_2(g)$;
B) $Ca(g) + WO_3(g) = CaO(g) + WO_2(g)$; D) $Ca(g) + SO(g) = CaO(g) + S(g)$.

[b]Ion intensities and D_0^0 reported (9) at 2180 K are discrepant by ~8 kcal mol^{-1}; we use ion intensities.

Heat Capacity and Entropy

Electronic levels (T_o) and vibrational-rotational constants of the observed states are from (1, 2, 3, 6, 7). The long-sought $a^3\Pi$ and $A'^1\Pi$ states of CaO, SrO and BaO were characterized by Field (1) using a new method for assignment of perturbations. This study resolved the long-standing controversy over low-lying electronic levels and confirmed that $X^1\Sigma^+$ is the ground state. We estimate the other potentially low-lying state ($^3\Sigma^+$) at 10000 cm^{-1} by assuming that it lies 1500 ± 1200 cm^{-1} (1, 4) below the isoconfigurational order of MgO(5). Rotational analysis of a band near 5470 Å was attributed (16) to CaO, but we question this assignment. Our thermodynamic functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \sum_i Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$.

PREVIOUS: December 1974 (1 atm) CURRENT: December 1974 (1 bar)

$S°(298.15\ K) = 56.6 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [2798]\ K$

$\Delta_f H°(0\ K) = -472.1 \pm 2.9\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -473.2 \pm 2.9\ kJ\ mol^{-1}$

Enthalpy of Formation

Sabatier (1), Mourlot (2), and von Wartenberg (3), all measured the enthalpy of solution of CaS in hydrochloric acid solution. Sabatier determined $\Delta_r H°(238.8) = -26.3 \pm 1.0$ kcal mol^{-1} while Mourlot determined $\Delta_r H°(291) = -26.7 \pm 1.0$ kcal mol^{-1} for CaS(cr) + 2HCl(100 H_2O, aq) + $CaCl_2$(100 H_2O,aq) + H_2S(aq). We derive $\Delta_f H°$(CaS, cr, 298.15 K) = -112.7 ± 2.0 kcal mol^{-1} and $\Delta_f H°$(CaS, cr, 298.15 K) = -112.3 ± 2.0 kcal mol^{-1} respectively, based on the following auxiliary data: $\Delta_f H°$(HCl·100 H_2O, aq, 298.15 K) = -39.657 kcal mol^{-1} (4), $\Delta_f H°$(H_2S, aq, 298.15 K) = -9.5 kcal mol^{-1} (4), and $\Delta_f H°$($CaCl_2$·100 H_2O, aq, 298.15 K) = -208.849 kcal mol^{-1} (5). Von Wartenberg measured $\Delta_r H(293.15) = -20.6 \pm 0.4$ kcal mol^{-1} for CaS(cr) + 2HCl(30 H_2O, aq) + H_2S(g). We derive $\Delta_f H°$(CaS, cr, 298.15 K) = -113.9 ± 0.6 kcal mol^{-1} based on the following auxiliary data: $\Delta_f H°$(HCl·30 H_2O, aq, 298.15 K) = -39.357 kcal mol^{-1} (4), $\Delta_f H°$(H_2S, g, 298.15 K) = -4.90 kcal mol^{-1} (4, 18), and $\Delta_f H°$($CaCl_2$·30 H_2O, aq, 298.15 K) = -208.33 kcal mol^{-1} (5).

[a]Reactions:
A) CaS(c) = CaS(g)
B) CaS(c) + H_2O(g) = CaO(c) + H_2S(g)
C) CaS(c) + 0.5O_2(g) = CaO(c) + 0.5S_2(g)
D) CaS(c) + 2SO_2(g) = $CaSO_4$(c) + S_2(g)
E) CaS(c) + 3$CaSO_4$(c) = 4CaO(c) + 4SO_2(g)
F) CaS(c) + CaS(c) = Ca(g) + S(g)
G) CaS(c) + 3S(g) = Ca(g) + 2S_2(g)

The calculated 3rd-law $\Delta_r H°(298.15\ K)$ may have an uncertainty of 0.5 kcal mol^{-1} since the JANAF Gibbs energy functions are partially based on the estimated Cp° data (above 300 K). The results of the majority of the equilibrium studies, (7, 8, 9, 10, 11, 12), are in very good agreement with the enthalpy of solution (1, 2, 3) studies within combined experimental errors. The mass spectrometric studies (13, 14) are not as reliable in condensed phase equilibrium as they are in gas phase equilibrium (18). A weighted average, $\Delta_f H°$(CaS, cr, 298.15 K) = -113.1 ± 0.7 kcal mol^{-1} is adopted in the tabulation.

Heat Capacity and Entropy

Anderson (15) measured the low temperature heat capacities of CaS(cr) from 58.1 - 294.9 K in an isothermal calorimeter. We have smoothed his Cp° data by a polynomial curve fitting technique and obtain S°(298.15 K) = 13.5 ± 0.3 cal K^{-1} mol^{-1} based on S° (60 K) = 1.192 cal K^{-1} mol^{-1}. The value of S°(60 K) is calculated from the combination of Debye and Einstein functions (θ_D = 284 and θ_E = 369). The Cp° values above 300 K are estimated by graphical extrapolation combined with a variant of method B of Kubaschewski et al. (16).

Fusion Data

The melting point of CaS(cr) is given as 2525°C (17).

Enthalpy of Formation

The adopted value for the enthalpy of formation, $\Delta_f H°(CaS, g, 298.15\ K)$ = 29.54±2 kcal mol^{-1}, is based on the Knudsen mass spectrometric studies analyzed below. The two independent studies are in very good agreement and we have adopted the average value. Our value is intermediate between $\Delta_f H°(298.15\ K)$ = 32 kcal mol^{-1} obtained by NBS (5) and $\Delta_f H°(298.15\ K)$ = 27.9±5 kcal mol^{-1} obtained by Mills (6) in a recent critical compilation. Using auxiliary JANAF data (4) and a recommended value for $D_0^0(S_2, g)$ = 100.69±01 kcal mol^{-1} (4), we calculate $D_0^0(CaS, g)$ = 78.7±2 kcal mol^{-1}.

Heat Capacity and Entropy

Electronic levels (T_{00}) and vibrational-rotational constants for the observed states are from the optical study of Blues and Barrow (3). Other low-lying electronic states and their vibrational-rotational constants are estimated in isoconfigurational groups by analogy with CaO (4) and from trends observed in the known states of the other alkaline-earth oxides and sulfides (4). Uncertainty in the energy and constants for the estimated states may contribute as much as 2-3 cal K^{-1} mol^{-1} to S° at 3000 K. The molecular constants have been corrected to the natural isotopic abundances. The thermodynamic functions are calculated using first order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \sum_i Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$.

Enthalpy of Formation

The ground state dissociation energy for $^{40}Ca_2$ was determined by Vidal (1) to be D_e = 1095.4 ± 0.5 cm^{-1} which gives D_0^0 = 1063.1 cm^{-1} using the spectroscopic data above. The adopted value for natural abundance Ca_2 was obtained from the $^{40}Ca_2$ value by correcting for the presence of the minor isotopic species (14). Using this value and the recommended value for $\Delta_f H°(Ca, g, 0\ K)$ = 177.33 kJ mol^{-1} as deduced from CODATA (2), we calculate the adopted value of $\Delta_f H°(Ca_2, g, 0\ K)$ = 341.92 kJ mol^{-1}. Correcting this value to 298.15 K using the current value of $H°(298.15\ K) - H°(0\ K)$ = 11.1895 kJ mol^{-1} for $Ca_2(g)$ and the CODATA value for Ca(cr), we obtain $\Delta_f H°(Ca_2, g, 298.15\ K)$ = 340.72 kJ mol^{-1}. Note that Brewer and Winn (3) calculated a value of D_0^0 (Ca_2, natural abundance) = 12.47 ± 1.7 kJ mol^{-1} based on some earlier spectroscopic work of Balfour and Whitlock (4). Gurvich (9) adopted a value of $\Delta_f H°(0\ K)$ = 342.266 ± 2.6 kJ mol^{-1} which is also based on the earlier study of (4).

Heat Capacity and Entropy

The thermal functions are calculated using a direct summation technique, analogous to the alkali dimers (13). Included in the calculation are the ground state ($^1\Sigma_g^+$) and the $^1\Sigma_u^+$ excited state at T_e = 18964 cm^{-1}. Spectroscopic constants for both states are taken from a detailed experimental investigation by Vidal (1) and are considered to be the most accurate. Presumably, other excited states, lower in energy than the $^1\Sigma_u^+$ state, exist as in the case of $Mg_2(g)$ (5), however no known experimental or theoretical constants have been published. The effect in the heat capacity of these missing states would probably be to cause the second Cp maximum to occur at lower temperatures, similiar to $Mg_2(g)$ (5). As with other diatomics possessing relatively shallow ground states, $Ca_2(g)$ is another example where the traditional integration methods of calculating thermal functions fail.

The rotational levels are extrapolated to high J values according to the method of Khachkuruzov (6) who proposed a simpler form of Wooley's method (7). For the ground state only, we included the so-called quasibound rotational levels above the dissociation limit (8) with J_{lim} = 209 and v_{max} = 34 as determined by Gurvich (9). Instead of performing separate calculations on all 21 isotopic species (made up of all possible dimeric combinations of the six isotopes), we adjust the spectroscopic constants of $^{40}Ca_2$ to a hypothetical natural abundance molecule using a standard reduced mass scaling routine (10). Thermal functions calculated in this manner should be trivially different from the exact procedure of performing the calculation on each isotope and combining the results according to the natural abundances of each species. The adopted value of $S°(298.15\ K)$ is 0.39 J K^{-1} mol^{-1} smaller than that calculated by (9). It should also be noted that the minor controversy in the literature over the correct assignment of the ground state (11) has apparently been satisfactorily resolved with the currently used data (12).

Enthalpy of Formation

The adopted value for the enthalpy of formation of Cl(g) is calculated from the dissociation energy of gaseous chlorine, D_0^0 (natural abundance) = 19999.10 ± 1.0 cm^{-1} (239.242 ± 0.012 kJ mol^{-1}). This value was calculated from the dissociation energy of $^{35}Cl_2(g)$, D_0^0 = 19997.28 ± 0.10 cm^{-1}, obtained from the extensive spectroscopic measurements of Douglas and Hoy (1). CODATA (2) used a slightly different value (D_0^0 = 19997.25 ± 0.3 cm^{-1} for $^{35}Cl_2$), as obtained by LeRoy and Bernstein (3) from the measurements of Douglas et al. (4), Brewer and Winn (5), Huber and Herzberg (6), and Gurvich et al. (7) have adopted one or the other of these two cited values. Wagman et al. (16) adopted a dissociation energy which is 63 cm^{-1} greater than our adopted value. Detailed discussions on the spectroscopic information are given by LeRoy (8), Coxon (9) and Douglas and Hoy (1).

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weight is taken from Moore (10, 11). Only two levels are included in the calculation. All other levels (observed and predicted) lie above 71954 cm^{-1}. Our calculations indicate that any reasonable method of filling in the missing levels and cutting off the summation in the partition function (12) has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels. Therefore, we list only the ground state and the first excited state. Extension to higher temperatures may require consideration of the higher excited states and utilization of different fill and cutoff procedures.

The thermodynamic functions at 298.15 K are in agreement with recent CODATA recommendations (2) except for two minor differences. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the monatomic halogens arise due to the use of slightly different values for R; this tables uses R = 8.31441 J K^{-1} mol^{-1}. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren et al. (13), Gurvich et al. (17), and Wagman et al. (16). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which are based on the 1981 scale (14) and the 1973 values (15), respectively.

CHLORINE, ION (Cl^+) IDEAL GAS M_r = 35.45245

$IP(Cl^+, g) = 192070 \pm 10\ cm^{-1}$

$S°(298.15\ K) = 167.556 \pm 0.005\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1370.807 \pm 0.01\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [1378.801]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^3P_2$	0.0	5
$^3P_1$	696.1	3
$^3P_0$	996.4	1
$^1D_2$	11653.5	5
$^1S_0$	27877.8	1

Enthalpy of Formation

$\Delta_f H°(Cl^+, g, 0\ K)$ is calculated from $\Delta_f H°(Cl, g, 0\ K)$ (1) using the spectroscopic value of IP(Cl) = 104591.0±0.3 cm^{-1} (1251.187±0.004 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ mol^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization potential and appearance potential data.

$\Delta_f H°(Cl^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Cl, g, 0\ K)$ by using IP(Cl) with JANAF (1) enthalpies, H°(0 K)-H°(298.15 K), for Cl(g), $Cl^+(g)$, and $e^-(g)$. $\Delta_r H°(Cl \rightarrow Cl^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the lowest four excited states; the next lowest level is approximately 93366 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and four excited states, with the energy of these states taken from recent study by Moore (2). The reported uncertainty is S°(298.15 K) is due to uncertainties in the relative ionic mass, the fundamental constants, and the position of the four lowest excited states. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (7).

Enthalpy of Formation

$\Delta_f H°(Cl^-, g, 0\ K)$ is calculated from $\Delta_f H°(Cl, g, 0\ K)$ (1) using the adopted electron affinity of EA(Cl) = 3.617±0.003 eV (348.985±0.289 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (10), is based on laser optogalvanic spectroscopic and plasma emission studies (5, 6). Additional information on $Cl^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 10), Rosenstock et al. (3) and Massey (4).

$\Delta_f H°(Cl^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Cl, g, 0\ K)$ by using EA(Cl) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Cl^-(g)$, Cl(g), and $e^-(g)$. $\Delta_r H(Cl^- \rightarrow Cl + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Cl^-(g)$ is given by Hotop and Lineberger (2, 10), Rosenstock et al. (3) and Massey (4). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

The entropy at all temperatures (0-6000 K) agrees within 0.001 J K^{-1} mol^{-1} with the values of Gurvich et al. (8) except for one minor difference. The entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the tabulation of Gurvich et al. (8) is based on 1 atm. The estimated uncertainty is due to uncertainties in the relative ionic mass and the fundamental constants which are based on the 1981 scale (9) and the 1973 values (7), respectively.

Enthalpy of Formation

Kulkarni and Dadape (1) have studied the reaction of $CoCl_2(g)$ with Co(cr) by a transpiration method. They used highly purified argon as the carrier gas and condensed the gaseous products on a mullite cold finger. Chemical and x-ray analyses of the condensate showed the presence of metallic cobalt. The transport of the Co metal was ascribed to the disproportionation of CoCl(g) according to the reaction 2 CoCl(g) = Co(cr) + $CoCl_2$(g). Partial pressures for CoCl(g) and $CoCl_2$(g) were reported for the temperature range 1395-1673 K. No consideration was given to possible dimerization of the dichloride. JANAF data (2) for $CoCl_2$(g) and Co_2Cl_4(g) are used to correct their $CoCl_2$ pressures for dimerization. The corrected pressures are 0.5% less than those of Kulkarni and Dadape (1) at 1395 K, and only 0.1% less at 1673 K. Hildenbrand (3) has also studied the disproportionation reaction of CoCl(g) by mass spectrometry. The monochloride was produced in the effusion cell (4) by vaporizing AgCl in the presence of metallic cobalt. The Ag^+ and $AgCl^+$ signals were also measured and used to derive equilibrium data for the process Ag(g + CoCl(g) = AgCl(g) + Co(g).

Hildenbrand (3)	C	7	1461-1605	6.21	9.87±0.35	2.4±1.1	45.6±1.5[a]	84.9

Reactions: (A) $CoCl_2(g) + Co(cr) = 2\ CoCl(g)$ (B) $CoCl_2(g) + Co(g) = 2\ CoCl(g)$ (C) Ag(g) + CoCl(g) = AgCl(g) + Co(g)

[a] $\Delta_r H°(298.15\ K)$(3rd law) combined with D°(AgCl, g, 298.15 K) = 75.0±0.5 kcal mol^{-1} (4).

The two sets of measurements of Hildenbrand (3) lead to consistent values for $\Delta_f H°$, while the results of Kulkarni and Dadape (1) suggest a value roughly 20 kcal mol^{-1} lower. In the same paper, Kulkarni and Dadape (1) reported vapor pressures for $CoCl_2(\ell)$ which were also determined by their flow technique. These vapor pressures have been shown to be incompatible with JANAF data (see $CoCl_2$(g) table). Furthermore, their value for the bond dissociation energy (D°(298.15 K) = 101.9 kcal mol^{-1}) of CoCl appears to be too high by comparison with similar data for other transition metal monochlorides. Values (5) of D° for the monochlorides of Cr, Mn, Ni, and Cu show a random variation of from 83.0 to 88.6 kcal mol^{-1}, suggesting a value for CoCl near 85 kcal mol^{-1}. The results of Hildenbrand (3) are in agreement with these predictions. It is further noted that Hildenbrand (4) has used a similar technique to study the monochlorides of Ca, Sr, and Ba. The results of these studies are quite consistent with JANAF heat of formation data (2). Thus, it appears that the method used by Hildenbrand (3, 4) is reliable, and we adopt an average value, $\Delta_f H°(298.15\ K)$ = 46.1 kcal mol^{-1}), of his two results. The uncertainty is estimated to be ± 3.0 kcal mol^{-1}. The adopted values for the ground state vibrational constants are judged to be of insufficient accuracy to warrant a Birge-Sponer calculation for D°(Co-Cl).

Heat Capacity and Entropy

The bond length is estimated as somewhat less than that for $CoCl_2$ (2). B_e is calculated from the value for r_e. The value for α_e is obtained from the other constants assuming a Morse potential function.

Several band systems have been observed in the electronic spectrum (6-9) of CoCl. Vibrational constants for the upper and lower states of the various systems have been summarized by Rosen (5). However, since it is not certain which of the observed electronic transitions involve the ground state, no assignments were made. Also, confusion exists as to whether some of the systems belong to triplet-triplet transitions (7-9), an electronic triplet (8), or whether they are all separate systems (9). We adopt the vibrational constants for the ground state suggested by Herzberg (10). Comparison of these values with those listed by Rosen (5) for the lower states of other systems for CoCl indicate that the adopted ω_e value may be uncertain by as much as ±5 cm^{-1}. Krishnamurty (8) has shown that the ground state electronic configuration for CoCl is either $^5\Sigma$ or $^3\Sigma$. We prefer a triplet ground state, since the electronic configuration for Co^{+1} is ^3F (11). Other transition metal monochlorides (5) and the corresponding unipositive metal ions (11) have the same ground state multiplicities. If the ground state is a quintet, then the value of S°(298.15 K) is increased by 1 cal K^{-1} mol^{-1}. The adopted electronic levels in the range 17,000-23,000 cm^{-1} are taken from the compilation of Rosen (5). Each level is assumed to be a separate system and is assigned a quantum weight of 3. Two triplet levels are also included at 11,000 and 25,000 cm^{-1}, since Rao and Rao (9) are believed to have observed two components of a triplet-triplet transition near 14,000 cm^{-1}. By analogy with similar data for other transition metal monochlorides (5), the lower triplet level is not expected to lie below 10,000 cm^{-1}. The adopted upper levels and assumed quantum weights contribute 0.31 cal K^{-1} mol^{-1} to the entropy of CoCl at 4000 K.

$S°(298.15\ K) = 101.182 \pm 0.021\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha+\beta) = 743\ K$

$T_{fus} = 918\ K$

$\Delta_f H°(0\ K) = -442.98 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -442.83 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_{trs}H° = 3.77\ kJ\ mol^{-1}$

$\Delta_{fus}H° = 15.9\ kJ\ mol^{-1}$

Enthalpy of Formation

The heat of solution ($\Delta_{sln}H°$) of CsCl(cr) in water has been measured by Forcrand (1, 2), Haigh (3), Samoilov (4, 6), and Rodnikova (5). Based on their results, Parker (7) derived the corresponding $\Delta_{sln}H°$(aq, ∞, 298.15) values as 4.30, 4.32, 4.08, 4.25, 4.18 and 4.18 kcal mol^{-1}. Borob'ev (8) determined the same quantity and reported $\Delta_{sln}H°(298.15\ K)$ (CsCl, aq, ∞, H_2O) = 4.20±0.04 kcal mol^{-1}. Using this value, 4.20 kcal mol^{-1}, and $\Delta_f H°(298.15\ K) = -61.69$ (9) and -39.952 kcal mol^{-1} (10) for Cs^+(aq, ∞) and Cl^- (aq, ∞, 298.15), respectively, we evaluate $\Delta_f H°$(CsCl, cr, 298.15 K) = -105.84±0.2 kcal mol^{-1}, which is adopted.

Heat Capacity and Entropy

Taylor (11) measured the low temperature heat capacities, 7.19 - 299.38 K, with an adiabatic calorimeter; the sample purity was >99.95%. Employing these data we derive the value $S°(298.15\ K) = 24.183$ cal $K^{-1}\ mol^{-1}$ based on $S°(7.19\ K) = 0.031$ cal $K^{-1}\ mol^{-1}$.

The high temperature enthalpies, 385.2 - 904.9 K, were measured by Kaylor (21, 12, 13), using a Bunsen ice calorimeter and a CsCl sample of 99.8% purity. The heat capacities derived from the reported enthalpy data at temperatures 385.2 - 740.5 K appear too low (less than the adopted $C_p°$'s systematically by 0.9 cal $K^{-1}\ mol^{-1}$ to join smoothly with the low temperature data at 298.15 K. The $C_p°$ values derived from the measured enthalpy data in the temperature range 760 - 920 K increase rapidly from 14.46 to 16.3 cal $K^{-1}\ mol^{-1}$. In order to rationalize this situation, we adopt the high temperature heat capacities, 298 - 743 K, for CsCl(α) obtained by linear extrapolation of the low temperature data. The $C_p°$ values for CsCl(β) are adjusted such that the rate of increase in heat capacities is linear and less rapid than the original one, and the total enthalpy remains essentially unchanged. The discrepancy between the high and low temperature $C_p°$ for CsCl(α) may be caused by the incomplete β → α phase conversion involved. In order to resolve this discrepancy, independent enthalpy measurements using a high purity sample with composition well characterized before and after each drop experiment seem necessary.

Transition Data

The temperature of transition (in K) has been reported by many investigators as 718 (14), 752 (15), 745 (16), 742 (21), 742.5 (12), 743 (20), and 733 (17), using different methods and samples of different purity. The value adopted is 743 K.

The heat of transition (in kcal mol^{-1}) was reported to be 1.8 (14), 1.55 (18), 1.4 (19), 0.80 (21), 0.58 (12), 0.90 (13), and 1.1 (17). A median value 0.90 kcal mol^{-1} is tentatively adopted.

Fusion Data

See the liquid table for details.

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ is calculated as the difference between $\Delta_f H°(298.15\ K)$ for CsCl(g) and CsCl(cr).

PREVIOUS: CURRENT: June 1968

$S°(298.15\ K) = [101.708]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 918\ K$

$\Delta_f H°(298.15\ K) = [-434.468]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 15.9 \pm 4.2\ kJ\ mol^{-1}$

Enthaply of Formation

$\Delta_f H°(CsCl, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(CsCl, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(918\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The enthalpies of CsCl(ℓ) at temperatures 923.6 - 1168.0 K were measured with a Bunsen ice calorimeter by Kaylor (1, 2). Dworkin (3) derived the heat capacity of CsCl(ℓ) as 18.5 cal K^{-1} mol^{-1} from enthalpy data at temperatures 918 - 980 K. This value is adopted since it is in agreement with the enthalpy values reported by Kaylor et al. (1, 2). The heat capacity at temperatures above 1168 and below 923.6 K is assumed to be 18.5 cal K^{-1} mol^{-1}. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting temperature (in K) of CsCl(cr) has been determined by many investigators as 904 ± 3 (4), 919 (5), 912 (6), 911 (7), 918 (8), 916 (9), and 919 (13). The cause of the discrepancies is probably due to the difference in purity of the samples. The melting temperature adopted is 918 K.

The heat of melting (in kcal mol^{-1}) was reported to be 4.84 (14), 4.97 (15), 4.58 (10), 4.96 (11), and 4.79 (2), which were obtained calorimetrically. Using a modification of Kelley's method of obtaining heat of melting from freezing point data on binary systems involving CsCl (16), we derive the value of $\Delta_{fus} H°$ as 3.6 - 4.0 kcal mol^{-1}, based on the following systems: CsCl-NaCl (5), CsCl-CuCl (6), CsCl-AgCl (6), CsCl-LiCl (8) and CsCl-$Cs_3(PO_3)_3$ (12). The heat of melting for CsCl(cr) is tentatively adopted as 3.8 kcal mol^{-1}. The $\Delta_{fus} H°$ values obtained calorimetrically are not used due to the uncertainties of the state of the sample before and after the enthalpy measurements.

Vaporization Data

T_{vap} = 1597.3 K is the temperature at which the calculated total pressures of CsCl(g) and $Cs_2Cl_2(g)$ equal one atmosphere. The vapor composition at T_{vap} is derived as CsCl 80.4% and Cs_2Cl_2 19.6%. The boiling point of CsCl(ℓ) has been determined by several investigators as 1562 (17), 1572 (18) and 1576 (19). The heat required to vaporize one mole of liquid to the above vapor mixture at T_{vap} is $\Delta_{vap} H°$.

Cesium Chloride (CsCl) Cl_1Cs_1(cr,l)

$S°(298.15\ K) = 256.070 \pm 0.021\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -237.98 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -240.16 \pm 4.2\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 213.08\ cm^{-1}$ $\omega_e x_e = 0.733\ cm^{-1}$ $\sigma = 1$
$B_e = 0.07134\ cm^{-1}$ $\alpha_e = 0.000332\ cm^{-1}$ $r_e = 2.906$ Å

Enthalpy of Formation

The total pressures of CsCl(g) and Cs_2Cl_2(g) over CsCl(cr) and CsCl(ℓ) in the temperature range 605-1577 K have been determined by manometric, transpiration and Knudsen effusion methods by many investigators. Based on the reported results, the partial pressures of CsCl(g) and Cs_2Cl_2(g) are calculated using the derived Gibbs energy functions for CsCl(cr), CsCl(ℓ), CsCl(g) and Cs_2Cl_2(g) and the enthalpies of sublimation and vaporization which are adjusted so that the sum of the calculated partial pressures of CsCl(g) and Cs_2Cl_2(g) approaches the measured total pressures, and the evaluated 2nd and 3rd law $\Delta_r H°(298.15\ K)$ values are in reasonable agreement. The results obtained are presented in the table below. The value of $\Delta_f H°(CsCl, g, 298.15\ K)$ adopted is -57.4±1 kcal mol^{-1} (-240.162±4.2 kJ mol^{-1}).

Gaydon (10) reported D_0^0(Cs-Cl) = 4.6±0.2 eV or 106.08±4.61 kcal mol^{-1}. Using this D_0^0 value and $\Delta_f H°(0\ K)$ = 18.683 and 28.52 kcal mol^{-1} for Cs(g) and Cl(g), we evaluate $\Delta_f H°(298.15\ K)$ = -59.4±4.6 kcal mol^{-1} for CsCl(g), which is in fair agreement with the adopted value.

*1 CsCl(cr) = CsCl(g); 2 CsCl(ℓ) = CsCl(g); A = Knudsen effusion; B = transpiration; and C = manometric.

Heat Capacity and Entropy

Clouser (11) studied the pure rotational spectra of CsCl(g) in the 0.96-3 mm range of the microwave region with the molecular-beam spectrometer, and derived the values of B_e, α_e, ω_e, $\omega_e x_e$ and r_e, which are adopted and corrected to the average isotopic species.

The Cs-Cl bond distance was measured as 3.06±0.03 Å by the electron diffraction method by Maxwell (12), which is not used. Similar values of B_e and α_e were reported by Honig (13) and Rice (14), determined from microwave and infrared spectra, respectively. Barrow (15) gave ω_e = 240 cm^{-1}($CsCl^{35}$) which is singificantly different from the adopted value 214.22 cm^{-1} for $CsCl^{35}$ and the value 209±6 cm^{-1} reported by Rice (14).

PREVIOUS: June 1968 (1 atm) CURRENT: June 1968 (1 bar)

COPPER CHLORIDE (CuCl) CRYSTAL M_r = 98.999

$S°(298.15\ K) = 87.03 \pm 4.2\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 703\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -138.07 \pm 1.7\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 10.230 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

There have been three calorimetric determinations of the enthalpy of formation. Thomsen (1) reported -32.875 kcal mol^{-1}. Bethelot (2) reported -35.6 kcal mol^{-1} and Wartenberg and Werth (3) reported -32.1±0.4 kcal mol^{-1}. In addition, values of the enthalpy of formation have been derived from several sets of equilibrium data. Noyes and Chow (4) from a study of cell potentials derived a $\Delta_r H°$ = 7.19 kcal mol^{-1} for the reaction Cu(cr) + HCl(∞,aq) + CuCl(cr) + 1/2 H_2(g) which yields $\Delta_f H°$(CuCl, 298.15 K) = -32.76 kcal mol^{-1}. Several investigators have studied the reaction 2 CuCl(cr) + H_2(g) + 2 Cu(cr) + 2 HCl(g) and its reverse reaction. These include Bagdasarian (5) who reported equilibrium constants which result in 2nd and 3rd law heats of reaction of 24.3 and 23.2 kcal mol^{-1}; Kapustinsky (6) who obtained similarly 20.1 and 21.8 kcal mol^{-1}; Shchukarev and Oranskaya (7) who obtained 25.4 and 21.5 kcal mol^{-1} for the 2nd and 3rd law heat of reaction. These yield values for $\Delta_f H°$(CuCl, 298.15 K) ranging from -32.1 to -34.8. Watanabe (8) from cell studies reports $\Delta_f H°$(CuCl, 298.15 K) = -34.6 kcal mol^{-1}. A value of $\Delta_f H°$(298.15 K) can also be obtained from $\Delta_f H°(CuCl_3, g)$ which is fixed independently and known with good precision. Using the 3rd law heat of sublimation of CuCl(cr) to trimer determined by Magee (9) [see trimer table], we obtain $\Delta_f H°$(CuCl, cr, 298.15 K) = -33.01±0.3 kcal mol^{-1}. A weighted average of -33.0±0.4 kcal mol^{-1} (-138.072±1.7 kJ mol^{-1}) was adopted.

Heat Capacity and Entropy

The entropy of CuCl was obtained from the several pieces of equilibrium data reported above and the adopted $\Delta_f H°$(298.15 K). A weighted average of 20.8±1 cal K^{-1} mol^{-1} was adopted for S°(CuCl, cr, 298.15 K). The enthalpy and heat capacity above 298.15 K have been reported by Krestovnikov and Karetnikov (10). However, these values were not adopted since they do not give reasonable heat capacities, and other data by these workers are not in agreement with established values. Heat capacities equal to those of AgCl, as given by Kelley (11), were adopted here above 298.15 K.

Fusion Data

The temperature and enthalpy of fusion were those selected by Kelley (12) from phase studies. The enthalpy of fusion was reported by Krestovnikov and Karetnikov (10) as 2.54 kcal mol^{-1}.

Sublimation Data

The enthalpy of sublimation was calculated from the adopted enthalpies of formation at 298.15 K for the reaction x CuCl(cr) + $(CuCl)_x$(g) where x = 1 or 3. See the individual ideal gas tables for details.

PREVIOUS. CURRENT: March 1966

COPPER CHLORIDE (CuCl) LIQUID M_r = 98.999

$S°(298.15\ K)$ = [93.752] J K^{-1} mol^{-1}
T_{fus} = 703°K

$\Delta_f H°(298.15\ K)$ = [-131.178] kJ mol^{-1}
$\Delta_{fus} H°$ = 10.230 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(CuCl, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(703\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity was estimated to be constant at 8 cal K^{-1} mol^{-1}. The entropy was calculated in a manner analogous to that of the heat of formation.

Boiling Data

The boiling point and heat of vaporization were calculated from the respective liquid, monomer and trimer gas tables. The boiling point, T_{vap} = 1485 K, was taken as the point where the total pressure reached 1 atm. At this point the partial pressures are 0.021 atm of monomer and 0.979 atm of trimer.

$S°(298.15\ K) = 237.207\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 91.21 \pm 1.7\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 91.09 \pm 1.7\ kJ\ mol^{-1}$

Electronic Level and Multiplicity

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 414.9\ cm^{-1}$ $\omega_e x_e = 1.577\ cm^{-1}$ $\sigma = 1$
$B_e = 0.1761\ cm^{-1}$ $\alpha_e = 0.001\ cm^{-1}$ $r_e = 2.050$ Å

Enthalpy of Formation

The enthalpy of formation was obtained from the equilibrium data of Brewer and Lofgren (1). They studied the reaction x Cu(cr) + x HCl(g) + Cu_2Cl_2(g) + x/2 H_2(g) by measuring the amount of CuCl formed when various ratios of HCl:H_2 were passed over heated copper. Brewer and Lofgren analyzed the data by a least squares fitting technique and deduced partial pressures of monomer and trimer. The monomer pressures were subjected to 2nd and 3rd law analysis and gave $\Delta_r H°(298.15\ K) = 46.85 \pm 3.2$ and 43.83 ± 0.4 kcal mol^{-1}, respectively. The 3rd law value yields $\Delta_f H°(CuCl, g, 298.15\ K) = 21.77 \pm 0.4$ kcal mol^{-1}, which was adopted.

Heat Capacity and Entropy

The molecular constants were corrected for normal isotopic abundance of both copper and chlorine and were calculated from the values for $^{65}Cu^{35}Cl$ given by Asundi, Rao and Brody (2). The rotational constants were in good agreement with those reported by Lagerqvist and Lazarova-Girsamov (3) for $Cu^{65}Cl^{35}$.

Enthalpy of Formation (Provisional-evaluation incomplete)

The enthalpy of formation was calculated from the selected value of $\Delta_f H°(298.15\ K)$ of HCl(g) given by JANAF (1), the appropriate thermal functions (see H_2, D_2, DCl tables, and HCl (1)) and zero point energies. The zero point energies of $H_2(g)$ and $D_2(g)$ are taken from Herzberg and Monfile (2). The zero point energies of HCl(g) and DCl(g), including the Dunham correction, were calculated from the molecular constants taken from Rosen (3).

Heat Capacity and Entropy

The vibrational and rotational constants at the respective electronic levels were taken from Rosen (3) and were adjusted to Cl^{35} = 75.4% and Cl^{37} = 24.6%.

The National Bureau of Standards prepared this table (4) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (4), we recalculate the table in terms of 1973 fundamental constants (5), 1975 atomic weights (6), and current JANAF reference states for the elements.

Point Group: C_s $\sigma = 1$

Bond Distances: O-Cl = 1.689 ± 0.003 Å O-D = 0.960 ± 0.004 Å

Bond Angle: D-O-Cl =102.5 ± 0.5°

Product of the Moments of Inertia: $I_A I_B I_C = 9.0222 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°$(DOCl, g, 298.15 K) is calculated from the JANAF selection (1) for $\Delta_f H°$(298.15 K) of HOCl(g), the JANAF thermal functions (1), and the zero point energies of H_2(g), D_2(g), HOCl(g), and DOCl(g). The zero point energies of H_2(g) and D_2(g) are those given by Herzberg and Monfils (2). The zero-point energies of HOCl(g) and DOCl(g) are estimated from vibrational frequencies as listed by JANAF (1) using the first-order relation, zero-point energy = $(\omega_1 + \omega_2 + \omega_3)/2$.

Heat Capacity and Entropy

The molecular constants B_0 and C_0 are from the microwave work of Mirri et al. (3). The constant A_0 is calculated from the molecular structure given by Mirri et al. (3) and is somewhat uncertain. The rotational constants A_0 = 11.105 cm^{-1}, B_0 = 0.474852 cm^{-1}, and C_0 = 0.454208 cm^{-1} have been adjusted for the natural isotopic abundance of Cl. The vibrational frequencies are from the infrared spectroscopic work of Ashby (4) and that of Schwager and Arkell (5) and have not been corrected for isotopic abundances.

Enthalpy of Formation

The selected value, $\Delta_f H°(ClF, 298.15\ K) = -12.02 \pm 0.1$ kcal mol^{-1}, is based on spectroscopic data. Three studies of the visible absorption bands of ClF, by Wahrahftig (1), by Schmitz and Schumacher (2), and by Stricker (3) agree in indicating a band convergence limit at 21,514±10 cm^{-1}. Assignment of this limit to $Cl(^2P_{1/2}) + F(^2P_{3/2})$ is supported by the dissociative ionization threshold for ClF reported by Dibeler et al. (4) whose ion-pair threshold, when reassigned to a hot band, corroborates this choice. From this assignment it follows that $D_0^0(ClF) = 58.98 \pm 0.02$ kcal mol^{-1}.

Combining this value with $D_0^0(F_2) = 36.7 \pm 0.2$ kcal mol^{-1}, reported by Berkowitz et al. (5), and with $D_0^0(Cl_2) = 57.177 \pm 0.006$ kcal mol^{-1}, given by Douglas et al. (6), one obtains $\Delta_f H°(ClF, 0\ K) = -12.0 \pm 0.1$ kcal mol^{-1} (-50.200 ± 0.42 kJ mol^{-1}).

Calorimetric values for $\Delta_f H°(298.15\ K)$, which bracket the selected value, are as follows: -11.6 kcal mol^{-1}, Wicke (7); -11.7 kcal mol^{-1}, Wicke and Friz (8); -14.34 and -15.0 kcal mol^{-1}, Schmitz and Schumacher (9); and -14.4 ± 0.8 kcal mol^{-1}, Nuttall and Armstrong (10).

Heat Capacity and Entropy

The vibrational and rotational constants of the respective electronic levels are taken from Rosen (11) and are adjusted to Cl^{35} = 75.4% and Cl^{37} = 24.6%. The value of α_e listed for the ground state by Rosen (11) has been divided by 10 to agree with the original data (12). The National Bureau of Standards prepared this table (13) by critical analysis of data existing is 1972 but used the incorrect value (11) for α_e of the ground state. Using the correct molecular constants and $\Delta_f H°$ selected by NBS (13), we recalculate the table in terms of 1973 fundamental constants (14), 1975 atomic weights (15), and current JANAF reference states for the elements. The thermodyanmic functions of this table may be biased at temperatures above about 3000 K due to neglect of rotational cut-off.

Enthalpy of Formation

The enthalpy of formation is based on an estimated $\Delta_r H°(298.15\ K)$ = 0 for the reaction $MgCl_2(g) + MgF_2(g) \rightarrow 2MgClF(g)$, using $\Delta_f H°(298.15\ K)$ = -95.85 and -176.2 kcal mol^{-1} for $MgCl_2(g)$ and $MgF_2(g)$, respectively.

Heat Capacity and Entropy

The bond angle is taken to be the value we have adopted for $MgCl_2(g)$. The Mg-Cl and Mg-F bond distances are assumed to be the same as those in $MgCl_2(g)$ and $MgF_2(g)$. The vibrational frequencies are the averages of those for $MgCl_2(g)$ and $MgF_2(g)$. The principal moments of inertia are: I_A = 0.0766 x 10^{-39}, I_B = 33.5997 x 10^{-39} and I_C = 33.6763 x 10^{-39} g cm^2.

Enthalpy of Formation

$\Delta_f H°$ is estimated as the mean of the $\Delta_f H°$ values (1) for $SO_2F_2(g)$ and $SO_2Cl_2(g)$. This corresponds to use of the mean bond energies, D(S-F) = 74 and D(S-Cl) = 36 kcal mol^{-1}, from SO_2F_2 and SO_2Cl_2, respectively. The resulting values of $\Delta_f G°$ are consistent with those methods of preparation for which thermodynamic tests are possible. Insufficient data preclude tests for preparation of SO_2ClF from AgF_2, CoF_3, MnF_3 and SbF_3. In other cases the tests are not stringent, since the calculated values of $\Delta_r G°$ are large and negative for the observed reactions.

Heat Capacity and Entropy

The point group and symmetry number are consistent with analysis of the spectral data, but the detailed structure is estimated from known coordinates of SO_2Cl in SO_2Cl_2 (1, 2) and SF in SO_2F_2 (1, 3). This estimate should be quite reliable since the SO_2 coordinates are almost identical in SO_2Cl_2 and SO_2F_2. The resulting structure has an O-S-Cl angle of 107.7°, an O-S-F angle of 108.4° and pricipal moments of inertia of I_A = 16.4743 x 10^{-39}, I_B = 29.0842 x 10^{-39} and I_C = 29.3031 x 10^{-39} g cm^2.

Vibrational frequencies are based on infrared spectra of the vapor (4) and confirmed by Raman spectra of the liquid (5). Birchall and Gillespie (4) assigned δ(FSCl) to a weak Raman band at 195 cm^{-1}, but force-constant calculations based on SO_2Cl_2 and SO_2F_2 predict a value near 300 cm^{-1} (6, 7). It appears that the twist(FSCl) and δ(FSCl) are nearly accidentally degenerate, so we assign them arbitrarily to the Raman band at 308 cm^{-1} and the infrared band at 300 cm^{-1}. The adopted assignments are those of Toyuki and Shimizu (6) and Pfeiffer (7). All adopted values lie between the analogous modes for SO_2Cl_2 and SO_2F_2. δ(FSCl) = 195 cm^{-1} is unlikely since it would lie below δ(ClSCl) = 209 cm^{-1} in SO_2Cl_2; also the intensity of such bending modes should be strong not weak (7).

715(1)	589(2)
549(1)	405(2)

Ground State Quantum Weight: 1 $\sigma = 3$

Point Group: C_{3v}

Bond Distances: F-Cl = [1.63] Å O-Cl = [1.46] Å

Bond Angles: F-Cl-O = [95° 10'] O-Cl-O = [119° 12']

Product of the Moments of Inertia: $I_A I_B I_C$ = [4.29248 x 10^{-114}] $g^3\ cm^6$

Enthalpy of Formation

Neugebauer and Margrave (1) measured the enthalpy of reaction of perchloryl fluoride and hydrogen.

$$ClO_3F(g) + 4H_2(g) = HF(aq., 0.6M) + HCl(aq, 0.6M) + 3H_2O(\ell)$$

NBS

The necessary, additional thermal data for the calculation of the enthalpy of formation was obtained by them from (2). Dibeler et al. (3) obtain a value of -5.3±4 kcal mol^{-1} from the observed appearance potential of Cl^+.

A

Heat Capacity and Entropy

The assignment of Lide and Mann (7), based upon the infrared spectra of the gas is supported by the Raman measurements of Powell and Lippincott (5).

The value of the spectroscopic constant B was obtained by Madden and Benedict (6) from a high resolution infrared spectrograph. The Cl-F bond distance was estimated assuming a single covalent bond with no ionic character as evidenced by the low dipole moment obtained by Maryott and Kreidler (7) Electron spin resonance results are explained by Brownstein (8), on the basis of a low dipole moment. The Cl-O distance was estimated to be that found in the Chlorate ion, Pauling (8). The resulting values of the bond angles and I_C are consistent with the measured I_B and the assumed bond lengths. The principal moments of inertia are: $I_A = I_B$= [15.9597 x 10^{-39}] and I_C = [16.8522 x 10^{-39}] g cm^2.

A calorimetric entropy of 60.17 cal K^{-1} mol^{-1} at 226.48 K was obtained by Koehler and Giauque (10) for the ideal gas. If the lattice doesn't discriminate between F and O atoms then at 0 K a residual entropy of 2.75 cal K^{-1} mol^{-1} exists and the third law entropy would be 62.92 cal K^{-1} mol^{-1}. This value may be compared with 62.64 obtained statistically. The difference 0.3 cal K^{-1} mol^{-1} is within the range found for other molecules and explained on the basis of some discrimination in the lattice, see Koehler and Giauque, (10) for references.

Ground State Quantum Weight: [1] $\sigma = 1$
Point Group: C_s
Bond Distances: P-Cl = 2.01 ± 0.04 Å P-F = 1.51 ± 0.03 Å P-O = 1.55 ± 0.03 Å
Bond Angles: F-P-F = 103° F-P-Cl = 103°
Product of the Moments of Inertia: $I_A I_B I_C = 1.90249 \times 10^{-113}\ g^3\ cm^6$

Enthaply of Formation

The $\Delta_f H°(298.15\ K)$ of $POClF_2$ was estimated to be -232 kcal mol^{-1} from the $\Delta_f H°(298.15\ K)$ of POF_3 by assuming bond energies of 120 kcal for D(P-F) and 80 kcal for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from Neale and Williams (1) and Neale et al. (2).

Essentially the same $\Delta_f H°(298.15\ K)$ may be obtained by assuming a $\Delta_r H° = 0$ for the following reaction: $POCl_3(g) + POF_3(g) \rightarrow POCl_2F(g) + POF_2Cl(g)$.

Heat Capacity and Entropy

The molecular constants were determined by Brockway and Beach (3) and by Williams et al. (4). Brockway and Beach (3) used electron diffraction. Williams et al. (4) measured microwave spectra. Brockway and Beach (3) assumed that the F-P-F and F-P-Cl angles were equal in POF_2Cl and $POFCl_2$. An analysis of Brockway and Beach's data by Williams et al. (4) indicates that the angles in POF_2Cl, $POFCl_2$, $POCl_3$, and POF_3 should be 103 rather than the reported 106±3. The principal moments of inertia are: $I_A = 18.7062 \times 10^{-39}\ g\ cm^2$, $I_B = 31.3539 \times 10^{-39}\ g\ cm^2$, and $I_C = 32.4373 \times 10^{39}\ g\ cm^2$.
The Raman spectra and vibrational frequencies for POF_2Cl were reported by Delwaulle and Francois (5). The frequencies were reassigned by Delwaulle and Francois (6).

Enthalpy of Formation

The $\Delta_f H°(298.15\ K) = -37.97$ kcal mol^{-1} was calculated from $\Delta_r H°(298.15\ K) = 25.83$ kcal mol^{-1} obtained by third law analysis of the equilibrium data of Schmitz and Schumacher (1) for the reaction $ClF_3(g) = ClF(g) + F_2(g)$. Similar values are obtained from the equilibrium data of Schafer and Wicke (2). Calorimetric values scatter widely, as summarized below; these were given little weight.

Source	Method	Reaction	Observation kcal mol^{-1}	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
1a	$K_p°$(523-623 K)	$ClF_3(g) \rightarrow ClF(g) + F_2(g)$	$\Delta_r H°(298.15\ K) = 25.83$	0.8 ± 0.3	-37.97
2a	$K_p°$(733 K)	$ClF_3(g) \rightarrow ClF(g) + F_2(g)$	$\Delta_r H°(298.15\ K) = 25.77$	---	-37.91
2b	$K_p°$(570-680 K)	$ClF_3(g) \rightarrow ClF(g) + F_2(g)$	$\Delta_r H°(298.15\ K) = 26.12$	6 ± 3	-38.26
1b	Calorimetric	$3\ NaCl + ClF_3 \rightarrow 3\ NaF + 2\ Cl_2$	$\Delta_r H°(291\ K) = -76.5$		-40.02
1c	Calorimetric	$NaCl + 0.5\ F_2 = NaF + 0.5\ Cl_2$	$\Delta_r H°(291\ K) = -39.5$		-42.0*
3	Calorimetric	$3\ NaCl + ClF_3 \rightarrow 3\ NaF + 2\ Cl_2$	$\Delta_r H°(298.15\ K) = -86.8$		-29.7
4	Calorimetric	$0.5\ F_2 + NaCl \rightarrow NaF + 0.5\ Cl_2$	$\Delta_r H°(293\ K) = -39.3$		-31.1**
5	Flow Reaction	$0.5\ Cl_2(g) + 1.5\ F_2(g) = ClF_3(g)$	$\Delta_r H°(473\ K) = -26.4$		-26.4

* from combination of 1b and 1c **from combination of 3 and 4

Heat Capacity and Entropy

The structural constants were obtained from the microwave study of Smith (3). The planar distorted "T" structure is similar to that derived from X-ray studies of the solid by Burbank and Bensey (4). Fundamental frequencies are taken from the infrared and Raman spectra of Claassen et al. (5). These data confirm the "T" structure as opposed to the pyramidal structure used in earlier spectral analyses.

Claassen et al. (5) calculate thermodynamic functions virtually identical with the JANAF values. These authors also correct the third law entropy reported by Grisard et al. (6) from measurements of heat capacity (14-285 K) and vapor pressure (226-303 K). The entropy at the normal boiling point becomes $S°(284.91\ K) = 67.04$ kcal mol^{-1} when a non-ideality correction consistent with the dimer-monomer vapor equilibrium is applied. The corresponding statistical entropy, $S°(284.91\ K) = 66.59$ kcal mol^{-1}, is consistent with the third law value within the probable error in the entropy of the liquid and the entropy of vaporization. The principal moments of inertia are: $I_A = 6.1123 \times 10^{-39}$, $I_B = 18.1568 \times 10^{-39}$ and $I_C = 24.2691 \times 10^{-39}$ g cm^2.

CHLORINE FLUORIDE (ClF_5) IDEAL GAS M_r = 130.445015

$S°(298.15\ K)$ = 310.739 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [-229.8 ± 63] kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [-238.5 ± 63] kJ mol^{-1}

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}	ν, cm^{-1}
712(1)	488(1)	732 (2)
541(1)	346(1)	[440](2)
486(1)	375(1)	302 (2)

Ground State Quantum Weight: [1] σ = 4
Point Group: C_{4v}
Bond Distances: $(Cl-F)_{basal}$ = 1.72 Å $(Cl-F)_{axial}$ = 1.62 Å
Bond Angle: F-Cl-F = 90°
Product of the Moments of Inertia: $I_A I_B I_C$ = 2.47347 x 10^{-113} g^3 cm^6

Enthalpy of Formation

The heat of formation was estimated by assuming that the ratio [(A•B•E•(ClF) - A•B•E•(ClF_3)]/[A•B•E•(ClF_3) - A•B•E•(ClF_5)] was equal to [A•B•E•(BrF) - A•B•E•(BrF_3)]/[A•B•E•(BrF_3) - A•B•E•(BrF_5)], where A•B•E• represents average bond energy. All values were taken from these tables. A•B•E•(ClF_5) was thus calculated to be 36 kcal mol^{-1} which leads to $\Delta_f H°$ = -57±15 kcal mol^{-1}.

Heat Capacity and Entropy

Begun et al. (1) have reported the infrared spectra of the gas and the Raman spectra of the liquid. Their assignments have been adopted here, including one frequency ν_8 obtained from a valence force-field treatment. The values are consistent with those of IF_5(g) and BrF_5(g). Smith (2) had previously reported three infrared bands. The structure of the molecule has not been determined but the spectra can only be interpreted assuming C_{4v} symmetry, this is in accord with IF_5 and BrF_5(g). Begun (1) assumed a square pyramidal structure with the chlorine in the base of the pyramid. There is some evidence that the chlorine may not lie in the basal plane but this would not appreciably affect the calculations. The structure adopted was that given by Begun (1). The principal moments of inertia are I_A = 37.3328 x 10^{-39} and $I_B = I_C$ = 25.7400 x 10^{-39} g cm^2.

Enthalpy of Formation

Leach and Roberts (1) have reported calorimetric measurements on the heat of hydrolysis of liquid sulfur chloride pentafluoride in aqueous caustic. Re-evaluation of their data using more recent auxiliary heats of formation (2) for aqueous NaOH, Na_2SO_4, NaCl, and NaF leads to $\Delta_f H°(ClSF_4, \ell, 298.15\ K) = -252.9 \pm 2.0$ kcal mol^{-1}. The adopted value for the gas is obtained from that for the liquid by addition of the heat of vaporization at 298.15 K. We estimate a value for $\Delta_{vap}H°(298.15\ K)$ equal to 4.6±0.5 kcal mol^{-1} from $\Delta_{vap}H° = 5.19$ kcal mol^{-1} reported by Griffiths (3) from an analysis of vapor pressure data. We assume that the reported $\Delta_{vap}H°$ value refers to a boiling temperature of 251.85 K, and we estimate the $\Delta_p C°$ of vaporization as -12 cal K^{-1} mol^{-1}. Earier vapor pressure measurements (4) lead to a lower value (3.9 kcal mol^{-1}) for $\Delta_{vap}H°(298.15\ K)$; however, we believe the earlier vapor pressure data are less reliable than the measurements of Griffiths (3).

Electron-impact studies by Harland and Thynne (5) on SF_6 and $ClSF_5$ have provided information on the appearance potentials (AP) for the formation of SF_5^+ and SF_5^- from these neutral molecules. Our analysis of their AP data (5) leads to $\Delta_f H°$ values which are more than 15 kcal mol^{-1} different than the adopted result.

The heat of atomization, $\Delta_a H°(0\ K)$, and S-Cl bond dissociation energy are calculated to be 431.8±4.5 kcal mol^{-1} and 59.6±6.0 kcal mol^{-1}, respectively. The latter value appears reasonable when compared with the mean values for the S-Cl bond strength in SCl_2 (63.8 kcal mol^{-1}).

Heat Capacity and Entropy

The structural parameters are taken from a study by Marsden and Bartell (6) who established the C_{4v} structure of $ClSF_5$ by a simultaneous least-squares analysis of electron diffraction and microwave spectroscopic data. The microwave data were based on the measurements of Kewley et al. (7). We use r_g distances to calculate the principal moments of inertia of $I_A = 30.9468 \times 10^{-39}$ and $I_B = I_C = 46.3888 \times 10^{-39}$ g cm^2.

The vibrational spectrum of $ClSF_5$ has been studied using various spectroscopic techniques (3, 8, 9). The observed vibrational frequencies show good agreement, but conflicting assignments have been reported. Griffiths (3) has argued that the fundamentals assigned as $\nu_6 = 396\ cm^{-1}$ and $\nu_{11} = 270\ cm^{-1}$ by Cross et al. (8) should be reversed. A recent Raman study (9) of $ClSF_5$ isolated in an argon matrix has identified the band at 396 cm^{-1} as the Cl component of the S-Cl stretching frequency (ν_4). A comparison of the vibrational spectra of $ClSF_5$ and $ClSeF_5$ (10) and results from two force field studies (6, 11) suggest that the low-frequency SF_5 bending mode (ν_{11}) should lie in the range 270-290 cm^{-1}. We adopt $\nu_{11} = 287\ cm^{-1}$ which was observed in the gas phase infrared spectra by Griffiths (3). As suggested by others (10, 11) we believe that the SF_2 out-of-plane deformation (ν_6) has not been resolved, and we use an estimated value (332 cm^{-1}) calculated from a general valency-force field (11). An independent force-field calculation (6) supports this value ($\nu_6 = 317\ cm^{-1}$). All other fundamentals are rounded values taken from the gas phase infrared and liquid phase Raman study of Griffiths (3).

Enthalpy of Formation

The dissociation energy of FeCl(g) was reported as 3±2 cal $K^{-1}\ mol^{-1}$ (69±46 kcal mol^{-1}) by Gaydon (1). The corresponding $\Delta_f H°$(FeCl, g, 298.15 K) was evaluated to be 56±46 kcal mol^{-1}. By comparing D_0^0(Fe-O) = 101 kcal mol^{-1} in FeO(g) with the coordinate bond energies obtained in organic complexes and iron carbonyl halides of E(Fe-O) = 59.4 and E(Fe-Cl) = 37.3 kcal mol^{-1}, reported by Jones et al. (2), the D_0^0(Fe-Cl) in FeCl(g) was estimated as 101 x (37.3/59.4) = 63.3 kcal mol^{-1}, yielding $\Delta_f H°$(FeCl, g, 298.15 K) = 64 kcal mol^{-1}. The adopted value of $\Delta_f H°$(298.15 K) for FeCl(g) is 60±20 kcal mol^{-1} (251.040±84 kJ mol^{-1}).

Heat Capacity and Entropy

The ground state configuration, ω_e and $\omega_e x_e$ (corrected to the average isotopic species) were obtained from Herzberg (3). The Fe-Cl bond distance was assumed to be the same as that in $FeCl_2$(g). Hence the values of B_e and α_e were calculated. The electronic levels and quantum weights were estimated by comparison with the electronic levels in Fe^+(g) reported by Moore (4), using the reasoning suggested by Hougen et al. (5). The total 30 for the quantum weight was obtained from the ground multiplet of Fe^+ and was split arbitrarily. The entropy values may be in error by a few entropy units due to the uncertainties in the low lying electronic levels.

PREVIOUS: June 1965 (1 atm) CURRENT: June 1965 (1 bar)

$S°(298.15\ K) = 186.901\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -92.127 \pm 0.21\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -92.312 \pm 0.21\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma$	0	1

$\omega_e = 2889.59\ cm^{-1}$ $\omega_e x_e = 52.06\ cm^{-1}$ $\sigma = 1$
$B_e = 10.5884\ cm^{-1}$ $\alpha_e = 0.3037\ cm^{-1}$ $r_e = 1.2746$ Å

Enthalpy of Formation

The selected value, Rossini's flow calorimetric measurement (1) of the direct combination of the elements, is essentially the same as that in the revised version (2) of NBS Circular 500. JANAF analyses of the more recent measurements are summarized below, while the earlier measurements have been reviewed by Rossini (1).

Experimenters	Date	Method	$\Delta_f H°(298.15\ K)$, $kcal\ mol^{-1}$	References
Johnson, Ambrose	1963	Comparison of HCl, H_2SO_4 and SO_2 by solution calorimetry	-22.14±0.12	2,3,4,5,6,7,8,9,10
Lachet, et al.	1949-52	Catalytic combination in flow calorimeter	-22.10±0.12	11,12
Roth, Richter	1934	Direct combination in bomb calorimeter	-21.90±0.05	13
von Wartenberg, Hanisch	1932	Direct combination in flow calorimeter	-21.90±0.01	14
Rossini	1932	Direct combination in flow calorimeter	-22.063±0.012	1
- - -	1922-63	$\Delta_f G°$ from e.m.f. and $\Delta_f S°$ from statistical mechanics	-22.02±0.03	15,16,17,18,19,20
Lewis	1906	Equilibria for reaction HCl(g) + 1/4 O_2(g) = 1/2 H_2O(g) + 1/2 Cl_2(g)	-22.30±0.44	21

The direct combination values of Roth-Richter (13) and von Wartenberg-Hanisch (14) are 0.7% less negative than that of Rossini; however, all of the other methods favor the more negative value. The Roth-Richter value may be affected by errors in the measurement of the extent of reaction by HCl titration (9, 22), since a set of experiments based on determination of the amount of H_2 gave a value of -22.02 $kcal\ mol^{-1}$.

Rossini's value is confirmed by a variety of independent methods. The solution calorimetry (3), though it is related through a complex reaction scheme, is based on species which are now quite well known. Emf measurements (15, 16, 17, 18, 19, 20) give $\Delta_f G°(298.15\ K) = -22.733$; assuming an uncertainty of 1.0 mv. in E°, this leads to $\Delta_f H°(298.15\ K) = -22.02 \pm 0.03$ when combined with the statistical entropies. The equilibria of Lewis (625-692 K) give $\Delta_f H°(298.15\ K) = -22.20 \pm 0.44$ (2nd law) and -22.30±0.04 (3rd law).

Heat Capacity and Entropy

Spectroscopic constants for HCl^{35} and HCl^{37} were selected from the work of Plyler et al. (23) and Haeusler and Barchewitz (24). The values were adjusted to 75.53% HCl^{35}.

Enthalpy of Formation

Our adopted value of $\Delta_f H°(HOCl, g, 298.15\ K)$ is based on the ultraviolet photometric equilibrium measurements of Knauth et al. (1) who determined $K_{333} = 0.132 \pm 0.008$ for the reaction $Cl_2O(g) + H_2O(g) = 2\ HOCl(g)$. Combining this result with JANAF auxiliary data (2), we obtain $\Delta_r H°(298.15\ K) = 2.66 \pm 0.10$ kcal mol^{-1}. When this result is combined with $\Delta_f H°(H_2O, g, 298.15\ K) = -57.795 \pm 0.01$ kcal mol^{-1} (3) and $\Delta_f H°(Cl_2O, g, 298.15\ K) = 19.46 \pm 0.4$ kcal mol^{-1} from (4), we obtain $\Delta_f H°(HOCl, g, 298.15\ K) = -17.8 \pm 0.5$ kcal mol^{-1}. This is in agreement with $\Delta_f H°(HOCl, g, 298.15\ K) = -18.0$ kcal mol^{-1} derived from similar equilibrium measurements of Molina and Molina (5). Niki et al. (6) also measured the gas phase equilibrium constant for the same reaction using an infrared method and obtained $K(295\ K) = 0.068 \pm 0.01$, from which we derive $\Delta_r H°(298.15\ K) = 2.75 \pm 0.2$ kcal mol^{-1}, and $\Delta_f H°(HOCl, g, 298.15\ K) = -17.8 \pm 0.6$ kcal mol^{-1} using the same auxiliary data as above. Hirsch et al. (7) have calculated a value of $\Delta_f H°(HOCl, g, 298.15\ K) = -19.2 \pm 4$ kcal mol^{-1} from ab initio results.

Connick and Chia (8) determined $\Delta_r H°(298.15\ K) = 5.06 \pm 0.13$ kcal mol^{-1} for the reaction $Cl_2(aq) + H_2O(\ell) = H^+(aq) + Cl^-(aq) + HOCl(aq)$. The auxiliary data (3) $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.315$ kcal mol^{-1}, $\Delta_f H°(Cl^-, aq, 298.15\ K) = -39.933$ kcal mol^{-1} and $\Delta_f H°(Cl_2, aq, 298.15\ K) = -5.6$ kcal mol^{-1} (9) give $\Delta_f H°(HOCl, aq, 298.15\ K) = -28.92 \pm 0.2$ kcal mol^{-1}. Similarly Morris (10) determined $\Delta_r G°(298.15\ K) = 10.282$ kcal mol^{-1} for the reaction $HOCl(aq) = H^+(aq) + OCl^-(aq)$. Using entropies from (9) we obtain $\Delta_r H°(298.15\ K) = 3.13 \pm 0.5$ kcal mol^{-1}, which when combined with auxiliary data from (9), leads to $\Delta_f H°(HOCl, aq, 298.15\ K) = -28.73 \pm 0.5$ kcal mol^{-1}. Combining the former value of $\Delta_f H°(HOCl, aq, 298.15\ K)$ with our adopted value for $\Delta_f H°(HOCl, g, 298.15\ K)$, we obtain $\Delta_r H°(298.15\ K) = -11.8 \pm 0.6$ kcal mol^{-1} for the heat of solution at infinite dilution of HOCl(g).

Heat Capacity and Entropy

The molecular structure given above is taken from the microwave work of Mirri et al. (11). The rotational constants used to determine the moments of inertia are taken from the high resolution infrared spectrum of Wells et al. (12) for the ν_1 vibrational band and are in reasonable agreement with rotational constants calculated from the above structure (the product of the moments of inertia calculated is 2% lower than our adopted value of $I_A I_B I_C$). Rotational constants are adjusted for the natural isotopic abundance of Cl and are $A_0 = 20.463\ cm^{-1}$, $B_0 = 0.50214\ cm^{-1}$, and $C_0 = 0.48910\ cm^{-1}$.

Vibrational frequencies are taken from Wells et al. (12 (ν_1)) and from Ashby (13 (ν_2, ν_3)). Values of ν are adjusted for the natural isotopic abundance of chlorine. The vibrations are expected to be anharmonic (11) but no anharmonicity constants are available. The lowest-lying excited state has been calculated to lie at 22,000 cm^{-1} (14). Omission of this state reduces $C_p°$ by 0.02 cal K^{-1} mol^{-1} and $S°$ by 0.002 cal K^{-1} mol^{-1} at 3000 K.

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated from values for $SiCl_4$, $SiHCl_3$ and SiH_4 (1). Data for $SiHCl_3$ (1) suggest that $\Delta_f H°$ shows minor deviations from linearity in the chlorosilanes. We assume that $\Delta_f H°$ has a cubic variation with a constant third difference of -1.5 kcal mol^{-1}. $\Delta_f H°$ values of the chloromethanes yield an almost constant third difference of -2.5 kcal mol^{-1} (2, 3, 1). This approximation corresponds to Allen's bond additivity scheme involving near-neighbor interactions taken two and three at a time (2). our adopted $\Delta_f H°$ is 0.4 kcal mol^{-1} more negative than that estimated by linear interpolation between $SiCl_4$ and SiH_4.

Heat Capacity and Entropy

The molecular structure is based on microwave data of Kewley et al. (4) for isotopic forms of the four monohalosilanes. The authors concluded that the silyl group is effectively the same in all four halides. We adopt effective (r_o) structural parameters rather than substitutional (r_s) parameters. These are in reasonable agreement with previous structures obtained by various methods (5). The principal moments of inertia are $I_A = 0.9972 \times 10^{-39}$ and $I_B = I_C = 12.6739 \times 10^{-39}\ g\ cm^2$.

Shimanouchi (6) selected vibrational frequencies from gas-phase infrared spectra of SiH_3X (X=F, Cl, Br) observed by Newman et al. (7). These authors' assignments for SiH_3F and SiH_3Br have been modified slightly by new data (1) obtained at higher resolution. Unpublished gas-phase frequencies of SiH_3X from the thesis of Robiette were quoted by Ball et al. (8). These are more consistent with the new data for SiH_3F and SiH_3Br, so we adopt them for SiH_3Cl. Monfils also obtianed partially resolved spectra of SiH_3Cl; his final paper (9) is not available to us.

We neglect excited states and assume the electronic ground state to be $^1A_1$ by analogy with CH_3Cl (10). Electronic absorption bands of SiH_3Cl were observed at ≥67000 cm^{-1} (11) and the absorption maximum in the lowest transition was estimated to be at ~62000 cm^{-1} (12). Contributions of these high-lying states would be negligible.

$S°(298.15\ K) = 94.86 \pm 4.2\ J\ K^{-1}\ mol^{-1}$
$T_{trs2} = 242.6\ K$
$T_{trs1} = 457.7\ K$
$T_{fus} = 793.2\ K$
$T_{dcm} = 612\ K$

$\Delta_f H°(0\ K) = -311.391 \pm 0.84\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -314.553 \pm 0.84\ kJ\ mol^{-1}$
$\Delta_{trs2} = 1.046\ kJ\ mol^{-1}$
$\Delta_{trs1} = 3.950\ kJ\ mol^{-1}$

Enthalpy of Formation

The equilibrium pressures for the reaction $NH_4Cl(cr) = NH_3(g) + HCl(g)$, at 320-636 K, have been measured by many investigators. Smits and de Lange (2), using the densi-tensimeter, determined the vapor pressure of $NH_4Cl(cr)$ and the density of the saturated vapor simultaneously. The results obtained indicate that within the range 527-626 K the saturated vapor completely dissociates into gaseous NH_3 and HCl. Based on this conclusion, the reported vapor pressure data were employed to evaluate the enthalpy of dissociation of $NH_4Cl(cr)$ by both the 2nd and 3rd law methods. The results are presented as follows.

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
(1)	521.6-619.1	43.18±0.08	42.11	-2.0±0.2
(2)	527.9-625.6	42.16±0.22	42.14	-0.2±0.4
(3)	525.4-615.0	42.02±0.06	42.20	0.2±0.1
(4)	471.3-557.0	42.43±0.09	42.08	-0.3±0.2
(5)	319.0-352.7	43.83±0.38	42.17	-4.9±1.1
(6)	503.4-611.4	41.27±0.38	42.12	1.3±0.8

The value of $\Delta_r H°(298.15\ K)$ adopted is 42.15±0.10 kcal mol^{-1}, yielding $\Delta_f H°(NH_4Cl, cr, 298.15\ K) = -75.8 \pm 0.20$ kcal mol^{-1}. The corresponding $\Delta_r H°(298.15\ K)$ value evaluated from solution data, selected by Parker (7) is 42.06 kcal mol^{-1}.

Heat Capacity and Entropy

The heat capacities (20.1-523.2 K) of $NH_4Cl(cr)$ have been measured by the following investigators: Ewald 138-301 K (8); Simon 20.1-290.8 K (9); Klinhardt 323.2-523.2 K (10); Simon et al. 204.5-275.8 K (11); Ziegler and Messer 107.2-320.2 K(12); Extermann and Weigle 228.2-248.2 (13) and Popov and Galchenko 373.2-523.2 K (14). These $C°_p$ data were plotted and a smooth $C°_p$ curve was drawn and adopted. The $C°_p$ values above 523 K were obtained by graphical extrapolation of the previous $C°_p$ curve. $S°(298.15\ K)$ was derived from the adopted low temperature data, based on $S°(20.1\ K) = 0.114$ cal K^{-1} mol^{-1}.

Transition Data

There are two transitions reported in the literature. The low temperature transition data (T_{trs2} and $\Delta_{trs2}H°$) were derived based on the heat capacity (107-320 K) data reported by Ziegler and Messer (12), in which the other T_{trs2} values given by previous investigators were reviewed. The high temperature transition data (T_{trs1} and $\Delta_{trs1}H°$) were taken from Klinkhardt (10). However, $\Delta_{trs1}H° = 1030$ and $\Delta H°(463.5\ K) = 1059.1 \pm 8.0$ cal mol^{-1} were reported by Scheffer (13), and Popov and Galchenko (14), respectively. Markowitz and Boryta (6) determined T_{trs1} to be 459.5±0.5 K.

Fusion Data

T_{fus} was obtained from Rassow (15)

Decomposition Data

The value of T_{dcm} was calculated as the temperature at which the vapor pressure of the decomposition products (NH_3 and HCl) equals 1 atm. By differential thermal analysis, T_{dcm} for $NH_4Cl(cr)$ was determined to be 611.4 K by Markowitz and Boryta (6).

$T_{trs} = 513.15\ K$
$T_{dcm} = [513]\ K$

$\Delta_f H°(0\ K) = -277.78 \pm 0.17\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -295.77 \pm 0.17\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 9.6 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

Gilliland and Johnson (1) and Birky and Hepler (2) have derived the enthalpy of formation for NH_4ClO_4(cr) from solution-calorimetric measurements. Their values are -70.74±0.32 and -70.63 kcal mol^{-1}, respectively. The mean of these is adopted here.

Heat Capacity and Entropy

Justice and Westrum (3) have measured the heat capacity from 5 to 350 K. The $C_p°$ values above 350 K were extrapolated. From the partial molar entropies of NH_4^+(aq) and ClO_4^-(aq) and the entropy of solution, Birky and Hepler (2) calculated a value of 43.6 cal K^{-1} mol^{-1} for S°(298.15 K). The fair agreement of this value with that derived from $C_p°$ suggests that there is no residual entropy at 0 K, as there would be if the NH_4^+ ion had a random orientation.

Transition and Decomposition Data

T_{trs} and $\Delta_{trs}H°$ were obtained (under a pressure of NH_3) by Markowitz (4). T_{dcm} was estimated from the report by Markowitz (4).

IODINE CHLORIDE (ICl) CRYSTAL M_r = 162.3575

$S°(298.15\ K) = 97.927\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 300.53\ K$

$\Delta_f H°(0\ K) = -36.395 \pm 0.105\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -35.422 \pm 0.105\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 11.602 \pm 0.008\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is that adopted by Calder and Giauque (1) from an analysis of the equilibrium data of McMorris and Yost (2) and Beeson and Yost (3). This yielded a enthalpy of formation of ICl(g), from which the heat of formation of ICl(cr) was calculated by using the heat of vaporization determined by Calder and Giauque (1).

Heat Capacity and Entropy

The heat capacity has been measured by Calder and Giauque (1) from 17-322 K. The entropy was calculated based on S°(15 K) = 0.592 cal K^{-1} mol^{-1}. Above 300 K the heat capacity data was extrapolated smoothly.

Fusion Data

All data were measured by Calder and Giauque (1).

IODINE MONOCHLORIDE (ICl) LIQUID M_r = 162.3575

$S°(298.15\ K) = [136.167]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 300.53\ K$

$\Delta_f H°(298.15\ K) = [-23.929]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 11.602 \pm 0.008\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(300.53 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity from 300.53 to 317.76 K has been measured by Calder and Giauque (1). Above 318 K it was extrapolated in a smooth manner. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

IODINE CHLORIDE (ICl) IDEAL GAS M_r = 162.3575

$S°(298.15\ K) = 247.567\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 19.141 \pm 0.105\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 17.506 \pm 0.105\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$1\Sigma^+$	0	1

$\omega_e = 382.18\ cm^{-1}$ $\omega_e x_e = 1.450\ cm^{-1}$ $\sigma = 1$
$B_e = 0.11298\ cm^{-1}$ $\alpha_e = 0.0005275\ cm^{-1}$ $r_e = 2.327$ Å

Enthalpy of Formation

The dissociation energy from spectroscopic measurements of ICl(g) has been summarized by Evans et al. (1) from which they adopt $D_0^0 = 49.64$ kcal mol^{-1}. McMorris and Yost (2) and Beeson and Yost (3) studied the equilibria NOCl = NO + 0.5Cl_2 and NO + ICl = NOCl + 0.5I_2(g) from which the equilibrium constant of ICl = 1/2 Cl_2 + 1/2 I_2(g) can be obtained. Calder and Giauque (4) have used 3rd law analysis to obtain $D_0^0 = 49.578 \pm 0.025$ kcal mol^{-1}. This value was adopted yielding $\Delta_f H°(298.15\ K) = 4.184 \pm 0.025$ kcal mol^{-1} (17.506 ± 0.105 kJ mol^{-1}).

Heat Capacity and Entropy

The molecular and vibrational constants were obtained from Herzberg (5). The values were then adjusted for the normal isotopic abundance of chlorine.

PREVIOUS: September 1965 (1 atm) CURRENT: September 1965 (1 bar)

$S°(298.15\ K) = 82.55 \pm 0.17\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1044\ K$

$\Delta_f H°(0\ K) = -436.38 \pm 0.25\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -436.68 \pm 0.25\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 26.284\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was calculated from the enthalpy of hydrolysis of K(cr), the enthalpies of solution of HCl(g) and KCl(cr), and the standard enthalpy of neutralization of a strong acid and strong base. Extensive measurements are available for all these quantities. Values used in the calculation, in addition to the enthalpy of formation for HCl(g), are summarized below.

Source	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1}
(1, 2, 3, 4)	$K(cr) + H_2O(\ell) + KOH(\infty H_2O) + 1/2\ H_2(g)$	-46.966 ± 0.05
(5, 2, 6)	$HCl(g) + HCl(\infty H_2O)$	-17.88 ± 0.015
(7)	$KCl(\infty H_2O) + KCl(cr)$	-4.115 ± 0.010
(7)	$KOH(\infty H_2O) + HCl(\infty H_2O) + KCl(\infty H_2O) + H_2O(\ell)$	-13.345 ± 0.025

Heat Capacity and Entropy

Low temperature heat capacities were obtained from the data (2.8-275 K) of Berg and Morrison (8). Previous measurements scatter around the selected values and are in good agreement. These include Strelkov et al. (12-298 K, 9), Clusius et al. (10-273 K, 10) and Southard and Nelson (17-285 K, 11). For other less extensive data see the review by Kelley and King (12). The entropy is based on the extrapolation $S°(2.8\ K) = 0.0006\ cal\ K^{-1}\ mol^{-1}$.

High temperature values are based on enthalpy data (373-1038 K) from Douglas (13). These values join smoothly with the low temperature values and are in excellent agreement with the enthalpy data (673-933 K) of Skuratov and Lapushkin (14) and the adiabatic heat capacities (334-721 K) of Mustajoki (15).

Fusion Data

The melting point and enthalpy of melting are from Douglas (13). Values of T_{fus} = 1043 K and 1045 K have been reported by Aukrust et al. (16) and Johnson and Bredig (17), respectively. The enthalpy of melting is confirmed by $\Delta_{fus} H° = 6.34\ kcal\ mol^{-1}$ obtained from enthalpy data by Dworkin and Bredig (18) and $\Delta_{fus} H° = 6.4$ and 6.5 kcal mol^{-1} based on enthalpy and phase diagram studies of Aukrust et al. (16), respectively.

$S°(298.15\ K) = [86.657]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}H° = 1044\ K$

$\Delta_f H°(298.15\ K) = [-421.791]\ kJ\ mol^{-1}$

$\Delta_{fus}H° = 26.284\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1044 K) - H°(298.15 K), *between the crystal and liquid.*

Heat Capacity and Entropy

The constant heat capacity, 17.59 cal K^{-1} mol^{-1}, was derived from enthalpy data (1053-1173 K) of Douglas (1). This value was extrapolated above and below the experimental range. A lower value of 16.7 cal K^{-1} mol^{-1} was derived by Dworkin (2) from enthalpy data (1050-1110 K) obtained in an enthalpy of melting study. The entropy of the liquid is calculated in a manner analogous to that used for enthalpy of formation.

Fusion Data

The melting point and enthalpy of melting are from Douglas (1). Values of T_{fus} = 1043 K and 1045 K have been reported by Aukrust et al. (3) and Johnson and Bredig (4), respectively. The enthalpy of melting is confirmed by $\Delta_{fus}H°$ = 6.34 kcal mol^{-1} obtained from enthalpy data by Dworkin and Bredig (5) and $\Delta_{fus}H°$ = 6.4 and 6.5 kcal mol^{-1} based on enthalpy and phase diagram studies of Aukrust et al. (3), respectively.

Vaporization Data

T_{vap}(equilibrium vapor) = ~1710 K is the temperature resulting in unit total pressure based on the calculated partial pressures of KCl(g) and K_2Cl_2(g). This value may be compared with boiling points of 1688 and 1690 K observed respectively by Ruff and Mugdan (6) and von Wartenburg and Albrecht (7). $\Delta_{vap}H°$ (equilibrium vapor) at the boiling point is calculated as the enthalpy *of vaporization of one mole of liquid to vapor containing 22.3 mole percent of dimer.* According to the selected functions, the amount of dimer at lower temperatures increases gradually to about 32 mole percent at the melting point then decreases rapidly over the crystal. T_{vap}(monomer) = ~1750 K is taken as the temperature at which the calculated Gibbs energy change is zero for KCl(ℓ) → KCl(g), while $\Delta_{vap}H°$ (monomer) is the corresponding enthalpy of vaporization.

Data on vapor pressures and dimer-monomer equilibrium are reviewed on the tables for KCl(g) and K_2Cl_2(g), respectively.

Enthalpy of Formation

The enthalpy of formation was calculated from that of the liquid based on $\Delta_{vap}H°(298.15\ K) = 49.5\ kcal\ mol^{-1}$ as selected from vapor pressure analyses summarized below. Partial pressures for the monomer were obtained from data of the first four sources by combination of total vapor pressures with PVT data or with transpiration data. Mass spectrometric values (5) are based on temperature variation of ion intensity. These same five studies were used in selection of $\Delta_r H°(298.15\ K) = 45.0\ kcal\ mol^{-1}$ for the dimer-monomer equilibrium (see K_2Cl_2).

The resulting tables were tested by comparison with total pressure data over the range 819-1691 K. Dimer-monomer ratios calculated from the tables were used to convert observed total pressures to the monomer pressures which are analyzed below (6-11). The results are consistent except near the boiling point where the observed pressures (10, 11) are 6-18 percent larger than those calculated. Knudsen effusion and transpiration studies over the crystal were not analyzed since they are in essential agreement with the torsion effusion data of source 6.

(a) Total vapor pressure (2, 3, 8). (b) 1235 K was omitted.

Heat Capacity and Entropy

Rotational and vibrational constants are based on the microwave studies of Clouser and Gordy (12). Earlier microwave data of Honig et al. (13) and electric resonance data of Lee et al. (14) are in excellent agreement. Infrared spectra of Rice and Klemperer (15) yield $\theta_e = 261 \pm 6\ cm^{-1}$ which is in good agreement. The constants were adjusted to a natural isotopic composition of 24.4 percent ^{37}Cl and 6.8 percent ^{41}K.

PREVIOUS: March 1966 (1 atm) CURRENT: March 1966 (1 bar)

$S°(298.15\ K) = 151.04 \pm 0.8\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 572.7\ K$
$T_{fus} = 798\ K$

$\Delta_f H°(0\ K) = -422.1 \pm 1.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -430.1 \pm 4.0\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 13.77\ kJ\ mol^{-1}$
$\Delta_{fus} H° = Unknown$

Enthalpy of Formation

The enthalpy of decomposition of $KClO_4$(cr) to KCl(cr) and O_2(g) was measured by Johnson and Gilliland (1), yielding $\Delta_f H°(298.15\ K) = -103.22 \pm 0.15\ kcal\ mol^{-1}$. Hofmann and Martin (2) burned a mixture of paraffin and potassium perchlorate and obtained $\Delta_f E(298.15\ K) = -1.73\ kcal\ mol^{-1}$ for the constant volume process corresponding to the reaction: $KClO_4(cr) = KCl(cr) + 2\ O_2(g)$. Correction of their value for $\Delta(pV)$ gives $\Delta_r H°(298.15\ K) = -0.55\ kcal\ mol^{-1}$ which agrees reasonably well to the corresponding value, $-0.96 \pm 0.10\ kcal\ mol^{-1}$, reported by Johnson and Gilliland (1). However, for the same reaction, $\Delta_r H°(298.15\ K) = -2.55 \pm 0.18\ kcal\ mol^{-1}$ was determined by Skuratov et al. (3). They measured this quantity by two different methods which gave concordant results. The value of $\Delta_f H°(298.15\ K)$ reported was $-101.9 \pm 0.2\ kcal\ mol^{-1}$. The value used here is the average of these four results.

Berthelot and Vieille (4) determined the difference between the enthalpy of explosion of ammonium picrate and that of an ammonium picrate-potassium perchlorate mixture, and also the difference between the enthalpy of explosion of potassium picrate and that of a potassium pricrate-potassium perchlorate mixture. They obtained $\Delta_r H° = 7.5\ kcal\ mol^{-1}$ for the reaction $KClO_4(cr) = KCl(cr) + 2\ O_2(g)$. From that the value of $\Delta_f H°(298.15\ K)$ was calculated to be $-111.9\ kcal\ mol^{-1}$. This value was not used.

Heat Capacity and Entropy

The low temperature heat capacities (12.53-298.07 K) were measured by Latimer and Ahlberg (5). The heat capacities above 298.15 K were estimated by comparison with those of $NaClO_4$(cr). $S°(298.15\ K)$ was reported by Kelley et al. (6), based on the low temperature heat capacities measured by Latimer and Ahlberg (5), using $S°(12.59\ K, extrap) = 0.14\ cal\ K^{-1}\ mol^{-1}$.

Transition Data

T_{trs} and $\Delta_{trs} H°$ were obtained from the U. S. National Bureau of Standards (7).

Fusion Data

T_{fus} was taken from the National Research Council (8).

PREVIOUS: CURRENT: June 1963

$S°(298.15\ K) = 59.300 \pm 0.063\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 883 \pm 2\ K$

$\Delta_f H°(0\ K) = -408.359 \pm 1.142\ J\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -408.266 \pm 1.142\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 19.832 \pm 0.42\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was obtained as follows:

	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}	Source
(1) $LiOH(aq, 100\ H_2O) + HCl(aq, 100\ H_2O) \rightarrow LiCl(aq, 201\ H_2O)$	-13.704 ± 0.014	(1)
(2) $Li(cr) + (aq, 1001\ H_2O)(\ell) \rightarrow LiOH\cdot(aq, 1000\ H_2O) + 1/2\ H_2(g)$	-53.142 ± 0.019	(2)
(3) $LiOH\cdot(aq, 1000\ H_2O) + LiOH\cdot(aq, 100\ H_2O) \rightarrow (aq, 900\ H_2O)(\ell)$	0.153 ± 0.040	(3)
(4) $1/2\ H_2(g) + 1/2\ Cl_2(g) \rightarrow HCl(g)$	-21.97 ± 0.09	(4)
(5) $HCl(g) \rightarrow (aq, 100\ H_2O)(\ell) \rightarrow HCl\cdot(aq, 100\ H_2O)$	-17.575 ± 0.100	(5, 6)
(6) $LiCl(aq, 201\ H_2O) \rightarrow LiCl(cr) + (aq, 201\ H_2O)(\ell)$	8.660 ± 0.010	(7)
(1)+(2)+(3)+(4)+(5)+(6) gives $Li(cr) + 1/2\ Cl\ (g) \rightarrow LiCl(cr)$	-97.578 ± 0.273	

A direct calorimetric determination by Siemonsen and Siemonsen (8) gave -94.8 ± 0.6 kcal mol^{-1}. However, the solution route was thought to be inherently more accurate and was adopted.

Heat Capacity and Entropy

The heat capacity between 15 and 325 K has been measured by Shirley (9) and by Oetting et al. (10). The two sets of data are in substantial agreement and were plotted together and used to evalute the entropy at 298. The extrapolation to 0 K was done assuming a T^3 law and yielded S°(15 K) = 0.019 cal K^{-1} mol^{-1}. Above 298, Douglas et al. (11) have made enthalpy measurements to 1200 K. Rodigina et al. (12) also made enthalpy determinations to 1100 K. These two sets of measurements were averaged and joined smoothly to the low temperature values.

Fusion and Transition Data

The melting point has been reported as follows: 880 K, Douglas et al. (11); 883 K, Rodigina et al. (12); 883 K, Haendler et al. (13); 879 K, Flood et al. (14); 879 K, von Wartenberg and Schulz (15). The highest value of 883 K was taken as representing the most pure samples. At this temperature the enthalpy equations of Douglas et al. yield a heat of fusion of 4.718 kcal mol^{-1}, those of Rodigina et al., 4.669 kcal mol^{-1}. Dworkin and Bredig (16) report a value of 4.76 ± 0.10 kcal mol^{-1} and quote 4.83 kcal mol^{-1} from a private communication from D. E. Smith. The average value $\Delta_{fus} H° = 4.74 \pm 0.10$ kcal mol^{-1} was adopted.

A transition at 838 K has been reported by Kislova and Bergman (17) but is not supported by the enthalpy measurements quoted above.

$S°(298.15\ K) = [78.435]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 883 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-390.755]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 19.832 \pm 0.42\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(LiCl, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(883\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity data from the melting point to 1100 K and 1200 K has been reported by Rodigina et al. (1) and Douglas et al. (2). The equation given by the former authors for the enthalpy of the liquid does not agree with their measurements and has been replaced by $H°(T;293.15) = 18.000T - 1.5 \times 10^{-3}T^2 - 2279\ cal\ mol^{-1}$, which fits to ±0.3%. The two sets of results were averaged and the equations were assumed to hold up to the normal boiling point. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

The equilibrium boiling point, T_{vap} = 1656 K, was taken from von Wartenburg and Schultz (3). The boiling point of the monomeric gas is defined as the temperature at which it reaches 1 bar pressure. This was obtained from the Gibbs energy crossover between liquid and monomeric gas.

Lithium Chloride (LiCl) Cl_1Li_1(cr,l)

$S°(298.15\ K) = 212.919\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -195.57\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -195.72 \pm 12.6\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma$	0.0	1

$\omega_e = 641.1 \pm 3.0\ cm^{-1}$ $\omega_e x_e = 4.2 \pm 0.3\ cm^{-1}$ $\sigma = 1$

$B_e = 0.7053\ cm^{-1}$ $\alpha_e = 0.0067\ cm^{-1}$ $r_e = 2.022$ Å

Enthalpy of Formation

Klemperer et al. (1) quote a private communication from W. H. Evans at the National Bureau of Standards giving $D_0^0 = 4.35$ cal $K^{-1}\ mol^{-1}$ which corresponds to $\sigma_f H°(0\ K) = -45.3 \pm 2.4$ kcal mol^{-1}. A 3rd law analysis of the vapor pressure data of Nesmeyanov and Sazonov (2) in conjunction with the relative concentration of monomer, dimer, and trimer at 870 K from the work of Miller and Kusch (3) leads to a monomer enthalpy of sublimation at 298.15 K of 52.56 kcal mol^{-1}, this gives $\Delta_f H°(298.15\ K) = -45.02$ kcal mol^{-1}. These values lead, however, to partial vapor pressures of the monomer which are less than half of the total vapor pressure near the boiling point. From the data of Miller and Kusch (3) it would be expected that the monomer would be the predominant species near the boiling point, a fact also substantiated by the work of Beusman (4), on the average molecular weight of the vapor. Thus it was decided to change the enthalpy of sublimation so as to give the correct normal boiling point and vapor pressures in the region 1400-1600 K and to approximate the relative concentrations of monomer, dimer, and trimer as found by Miller and Kusch at 870 K. A monomer heat of sublimation at 298.15 K of 50.8 kcal mol^{-1} was chosen, which gives $\Delta_f H°(298.15\ K) = -46.778$ kcal mol^{-1}. The normal boiling point was taken as 1656 K as determined by von Wartenburg and Schulz (5) and the boiling point of LiCl(g) was found as 1701 K from the Gibbs energy crossover between liquid and gas.

Heat Capacity and Entropy

The spectroscopic constants were taken from Klemperer et al. (1). The value of α_e was calculated by the value of a_1 given by the Rittner potential function and the equation given by Klemperer et al. (1). The value of r_e was taken from (6).

$S°(298.15\ K) = [126 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 509\ K$

$\Delta_f H°(0\ K) =$ Unknown

$\Delta_f H°(298.15\ K) = -380.7 \pm 2.9\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [29.29]\ kJ\ mol^{-1}$

Enthalpy of Formation

The heats of reaction ($\Delta_r H°$) involving $LiClO_4$(cr) has been determined by several investigators as follows:

Source	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Gilliland and Johnson (1)	$LiClO_4(cr) + KCl(cr) \rightarrow LiCl(cr) + KClO_4(cr)$	-5.86±0.06	-90.34
Markowitz, et al. (2)	$LiOH(225\ H_2O) + HClO_4(225\ H_2O) \rightarrow LiClO_4\ (451\ H_2O) + H_2O(l)$	-13.54±0.09	-91.7
Birky and Hepler (3)	$LiClO_4(cr) \rightarrow Li^+(aq) + ClO_4^-(aq)$	-6.31±0.13	-91.11

The adopted value, $\Delta_f H°(298.15\ K) = -91.0$ kcal mol^{-1}, for $LiClO_4$(cr) is the weighted average of the three values listed.

Heat Capacity and Entropy

Heat capacities and S°(298.15 K) were estimated by comparison with those of $KClO_4$(cr).

Fusion Data

T_{fus} was obtained from Richards and Willard (4). The value of $\Delta_{fus} H°(509\ K)$ was estimated by comparison with the value, $\Delta_{fus} H°(528\ K) = 5.4$ kcal mol^{-1}, for $NaClO_3$(cr) reported by Kelley (5).

$S°(298.15\ K) = [164.611]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 509\ K$

$\Delta_f H°(298.15\ K) = [-358.355]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [29.3]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(LiClO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(LiClO_4, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(509\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ for $LiClO_4(\ell)$ was estimated by comparison with that for $NaClO_3(\ell)$. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting temperature (T_{fus}) was obtained from Richards and Willard (1). The value of $\Delta_{fus} H°(509\ K)$ was estimated by comparison with the value, $\Delta_{fus} H°(528\ K) = 5.4\ kcal\ mol^{-1}$, for $NaClO_3(cr)$ reported by Kelley (2).

MAGNESIUM CHLORIDE (MgCl) IDEAL GAS M_r = 59.758

$S°(298.15\ K) = 233.413\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -43.3 \pm 42\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -43.5 \pm 42\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^2\Sigma$	0	2

$\omega_e = 462.4\ cm^{-1}$ $\omega_e x_e = 2.02\ cm^{-1}$ $\sigma = 1$
$B_e = [0.2417]\ cm^{-1}$ $\alpha_e = [0.0014]\ cm^{-1}$ $r_e = 2.199$ Å

Enthalpy of Formation

The enthalpy of formation is calculated from D_0^0 = 3.2 eV reported by Herzberg (1). D_0^0 = 2.7±0.7 eV reported by Gaydon (2), yields $\Delta_f H°(MgCl, g, 298.15\ K) = 1.0 \pm 16\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

Spectroscopic constants were reported by Herzberg (1) and adjusted for natural isotopic abundance. The bond length was reported by Morgan and Barrow (3). B_e and α_e were estimated by the method suggested by Herzberg (1).

MAGNESIUM CHLORIDE, ION ($MgCl^+$) IDEAL GAS M_r = 59.75745

$S°(298.15\ K) = [228.6 \pm 8]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 646.6 \pm 84\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [652.704] \pm 84\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^1\Sigma_g^+$	0	1
$^3\pi_u$	[9000]	6
$^1\pi_u$	[11000]	2
$^3\Sigma_g^-$	[20000]	3
$^1\Delta$	[25000]	2
$^1\Sigma^+$	[30000]	1

$\omega_e = [400]\ cm^{-1}$ $\omega_e x_e = [2]\ cm^{-1}$ $\sigma = 1$

$B_e = [0.2415]\ cm^{-1}$ $\alpha_e = [0.00164]\ cm^{-1}$ $r_e = [2.2]$ Å

Enthalpy of Formation

The ionization potential of MgCl(g) was reported to be 7.2, 7.5 ± 0.5 and 7 ± 1 eV by Krasnov (1), Hildenbrand (9), and Beckett (2), respectively. The corresponding heats of formation at 298 K for $MgCl^+$(g) are derived as 156, 163, and 151 kcal mol^{-1}, using $\Delta_f H°(MgCl, g, 0\ K) = -10.34$ kcal mol^{-1} from the JANAF MgCl(g) table (March 31, 1966). The value of $\Delta_f H°(298.15\ K)$ for $MgCl^+$(g) is tentatively selected as 156±20 kcal mol^{-1} (652.704±84 kJ mol^{-1}).

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as NaCl(g) which is esoelectronic with $MgCl^+$(g). The six electronic states are obtained from Fougere (3). The corresponding electronic levels are estimated by comparison with the isoelectronic molecules BeS (4), BeO (5, 6), and MgO (5, 7). The bond distance is estimated by the method suggested by Krasnov (8). The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for MgCl(g) and NaCl(g). B_e and α_e are calculated by the method recommended by Herzberg (5).

Ground State Quantum Weight: 1 σ = 1

Point Group: C_s

Bond Distances: O-N = 1.143 ± 0.012 Å N-Cl = 1.976 ± 0.005 Å

Bond Angle: O-N-Cl = 113.0° ± 0.7°

Rotational Constants: A_0 = 2.8492 cm^{-1} B_0 = 0.19034 cm^{-1} C_0 = 0.17842 cm^{-1}

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from $\Delta_r H°$ = 18.43±0.06 kcal mol^{-1} derived by 3rd law analysis of equilibrium data (1) for 2ONCl(g) + 2NO(g) + Cl_2(g). 2nd law analysis yields $\Delta_r H°$ = 18.39±0.07 and an entropy deviation of -0.09±0.16 cal K^{-1} mol^{-1} from the 3rd law $\Delta_r S°$. Data analyzed cover a temperature range of 372.7 to 491.3 K and consist of a combination of three runs reported by Beeson and Yost (1). Combination is justified by the mutual consistency of the three runs, which involved excess NO, excess Cl_2, and roughly the stoichiometric ratio of NO and Cl_2, respectively. Earlier data reviewed by Bichowsky and Rossini (2) are considered less reliable.

Heat Capacity and Entropy

We list structural parameters which approximate the adopted rotational constants (3) obtained from microwave spectra of three isotopic molecules. These structural parameters are minor modifications of those given by Millen and Pannell (3). Changes are well within the ranges specified by the authors but give improved agreement with rotational constant A_0. Literature values include (O-N) = 1.139±0.012 (3), 1.14±0.02 (4, 7) and 1.17±0.06 Å(5, 6) (N-Cl) = 1.975±0.005 (3), 1.95±0.01 (4), 1.95±0.06 (5, 6) and 1.97±0.01 Å (7, 6); and angle (O-N-Cl) = 113.33°±0.67° (3), 116°±2° (4), 114°±3° (5, 6) and 113°±2°(7, 8). The earlier values (4, 5, 7) resulted from electron-diffraction data (4) and two separate analyses (5, 7) of older microwave data (6). Rotational constants are adjusted for the natural isotopic abundance of Cl. A_0 is relatively uncertain.

Observed ν values and anharmonicity constants are from the gas-phase infrared study of Jones et al. (8), who reviewed earlier spectral data. Values of ν are adjusted for the natural isotopic abundance of chlorine. The anharmonicity constants differ from, and supersede, earlier values (9) used by Gordon (10) in calculating thermodynamic functions for ONCl.

New functions have been calculated through the courtesy of B. J. McBride (11), who used the above vibrational and rotational constants with first and second order corrections (method NRRA02) in the NASA-Lewis computer program (12). We adopt these functions directly for 0 to 298.15 K and reproduce the functions at higher temperatures by integration of $C_p°$.

367(1)	651(1)

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_{2v}
Bond Distances: N-Cl = 1.83 Å N-O = 1.21 Å
Bond Angles: O-N-O = 129.5° O-N-Cl = 115.25°
Product of the Moments of Inertia: $I_A I_B I_C = 2.36673 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

The selected enthalpy of formation was obtained from the recalculation of the heat of reaction $ClNO_2 + NO = ClNO + NO_2$ which has been measured calorimetrically as -9.27 kcal mol^{-1} by Ray and Ogg (1). Not only the thermal effects of $2NO_2 = N_2O_4$ but also $NO + NO_2 = N_2O_3$ (a minor one) have been considered in calculation. Using all JANAF auxiliary data for ClNO, NO, NO_2, N_2O_3 and N_2O_4, the recalculation gives $\Delta_f H°(298.15\ K) = 2.90 \pm 0.4$ kcal mol^{-1} for $NO_2Cl(g)$. For the reaction $ClNO + N_2O_5 = ClNO_2 + 2NO_2$ also measured by Ray and Ogg (1), the recalculation gives $\Delta_f H°(NO_2Cl, g, 298.15\ K) = 2.56 \pm 0.4$ kcal mol^{-1}.

Martin and Koehlein (2) have determined kinetically the heat of reaction, $\Delta_r H°(273.15\ K) = 3.10$ kcal mol^{-1} for the reaction $NO_2 + NOCl = NO + NO_2Cl$ which gives $\Delta_f H°(298.15\ K) = 1.90 \pm 1$ kcal mol^{-1} for $NO_2Cl(g)$. Cordes and Johnston (3) have also determined kinetically the $\Delta_r H°(0\ K) = 29.5$ kcal mol^{-1} for the reaction $NO_2Cl = NO_2 + Cl$ which gives $\Delta_f H°(298.15\ K) = 6.3 \pm 0.3$ kcal mol^{-1}.

Heat Capacity and Entropy

The selected bond distances and bond angles were obtained from microwave spectrum studies by Clayton et al. (4). Millen and Sinnott (5), reported bond distance N-Cl = 1.840 Å, N-O = 1.202 Å and angle ONO = 130° 35' from the microwave measurement. These two are in good agreement.

The selected vibrational frequencies were obtained from infrared and Raman spectrum measurements by Ryason and Wilson (6). However, the assignment of the fundamental frequencies has been revised by Dodd et al. (7) and Morino and Tanaka (8). Morino and Tanaka's assignment was adopted. The principal moments of inertia are $I_A = 6.3641 \times 10^{-39}$, $I_B = 16.3632 \times 10^{-39}$ and $I_C = 22.7272 \times 10^{-39}\ g\ cm^2$.

PREVIOUS. December 1965 (1 atm) CURRENT: December 1965 (1 bar)

SODIUM CHLORIDE (NaCl) CRYSTAL M_r = 58.44277

$S°(298.15\ K) = 72.115 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1073.8 \pm 1.0\ K$

$\Delta_f H°(0\ K) = -410.693 \pm 0.34\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -411.120 \pm 0.34\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 28.158 \pm 0.17\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is based on $\Delta_f H°(298.15\ K) = -57.39$ and -39.95 kcal mol^{-1} for $Na^+(aq,\infty)$ and $Cl^-(aq,\infty)$, respectively, and on the enthalpy of solution, $\Delta_{sln} H°(298.15\ K) = 0.922$ kcal mol^{-1} for NaCl. These values were reported in a personal communication from Wagman (1).

Heat Capacity and Entropy

The low temperature values are based on the heat capacities (3-266 K) reported by Barron et al. (2). The earlier work of Clusius et al., (3) results in a slightly higher entropy, $S°(298.15\ K) = 17.33$ cal $K^{-1}\ mol^{-1}$, but a lower heat capacity at room temperature, $C_p°(298.15\ K) = 11.9$ cal $K^{-1}\ mol^{-1}$. The high temperature values have been obtained by re-analysis of the enthalpies (672 - 1279 K) of Dawson et al. (4), using the new value for $C_p°(298.15\ K)$. The resulting tables agree within ±0.1 kcal mol^{-1} with the enthalpies (812 - 1058 K) of Roth and Bertram (5). The enthalpies (540 - 1037 K) of Magnus (6) agree well at the lower temperatures but are about 0.3 kcal mol^{-1} smaller near the melting point.

Fusion Data

The melting temperature was taken from Dawson et al. (4) and the heat of melting was obtained by re-analysis of their crystal and liquid enthalpies. Values of $T_{fus} = 1073$ K and $\Delta_{fus} H° = 6.69 \pm 0.06$ kcal mol^{-1} were reported by Dworkin and Bredig (7).

Sublimation Data

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details, see the tables for NaCl gases).

PREVIOUS: December 1960 CURRENT: September 1964

$S°(298.15\ K) = [95.055]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1073.8 \pm 1.0\ K$

$\Delta_f H°(298.15\ K) = [-385.923]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 28.158 \pm 0.17\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(NaCl, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1073.8\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

These were obtained by analysis of the enthalpies (1076 - 1279 K) of Dawson et al. (1). The heat capacity was extrapolated to a constant value of 16.0 at the higher temperatures. A glass transition was assumed at 800 K and below this temperature $C_p°$ was taken to that of the crystal.

$S°(298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The melting temperature was taken from Dawson et al. (1) and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of T_{fus} = 1073 K and $\Delta_{fus} H°$ = 6.69±0.06 kcal mol^{-1} were reported by Dworkin and Bredig (2).

Sublimation Data

The vapor in equilibrium with NaCl contains both monomeric and polymric forms (for details see the tables for NaCl gases).

$\omega_e = 363.62\ cm^{-1}$ $\omega_e x_e = 1.72\ cm^{-1}$ $\sigma = 1$
$B_e = 0.21691\ cm^{-1}$ $\alpha_e = 0.001598\ cm^{-1}$ $r_e = 2.3606$ Å

Enthalpy of Formation

The enthalpy of formation is based on a enthalpy of sublimation $\Delta_{sub}H°(298.15\ K) = 54.9\ kcal\ mol^{-1}$ obtained from the more consistent sets of vapor pressure data by correction for the presence of dimer. Observed vapor pressures were converted to monomer pressures by use of dimer-monomer ratios calculated from JANAF Gibbs energy functions and $\Delta_r H°(298.15\ K) = 48.6\ kcal\ mol^{-1}$ for the reaction $(NaCl)_2(g) \rightarrow 2\ NaCl(g)$. Higher polymeric species were neglected. Analyses of the resulting monomer pressures are summarized below.

Heat Capacity and Entropy

The molecular constants are based on molecular beam studies of the rotational spectra by Clouser and Gordy (9) and on microwave studies by Honig et al. (10). The infrared spectra of Rice and Klemperer (11) give a frequency in close agreement (366 cm^{-1}).

PREVIOUS: December 1964 (1 atm) CURRENT: December 1964 (1 bar)

$S°(298.15\ K) = [142.256]\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 581\ K$
$T_{fus} = 755\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -382.752 \pm 0.92\ kJ\ mol^{-1}$
$\Delta_{trs} H° = [13.98]\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

Gilliland and Johnson (1) measured the enthalpy of solution of $NaClO_4$(cr) and gave $\Delta_f H°(298.15\ K) = -92.48 \pm 0.22\ kcal\ mol^{-1}$ for $NaClO_4$(cr). The enthalpy of dilution of $NaClO_4$(cr) was measured by Vanderzee and Swanson. The data led to $\Delta_f H°(298.15\ K) = -91.464\ kcal\ mol^{-1}$ which agrees very well with the data reported by Gilliland and Johnson (1). The value of $\Delta_f H°(298.15\ K)$ was reported to be $-92.18\ kcal\ mol^{-1}$ (3), based upon the data prior to 1950. Vorob'ev, et al. (4) measured the enthalpy of decomposition of $NaClO_4$(cr) into NaCl(cr) and O_2(g) and gave $\Delta_f H°(298.15\ K) = -90.68 \pm 0.3\ kcal\ mol^{-1}$ for $NaClO_4$(cr). The value reported by Gilliland and Johnson (1) was used.

Heat Capacity and Entropy

Heat capacities and S°(298.15 K) wee estimated by comparison with those for $NaClO_3$(cr) and $KClO_4$(cr), respectively.

Transition Data

T_{trs} was reported in (3). $\Delta_{trs} H°$ was estimated from that for $KClO_4$(cr).

Fusion Data

T_{fus} was obtained from (5).

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K)$, is based on our third law analysis of unpublished mass spectrometry data (7 points, 1400-1540 K) of Hildenbrand (1) for the reaction $Ni(g) + NiCl_2(g) = 2NiCl(g)$. Our analysis of this data yields 2nd and 3rd law values for $\Delta_f H°(298.15\ K)$ of 43.0±1.3 kcal mol^{-1} and 43.5±1.0 kcal mol^{-1}, respectively, with a drift of 0.64±1.17 cal K^{-1} mol^{-1}. These values are in good agreement with a value of $\Delta_f H°(298.15\ K)$ = 42.9±5.4 kcal mol^{-1} based on the dissociation energy of 88±5 kcal mol^{-1} reported by Bulewicz et al. (2) using flame photometry. Additional studies include an analysis by Rao and Dadape (3) of the equilibrium $NiCl_2(g) + Ni(cr) \rightarrow 2NiCl(g)$ by the flow method. Our analysis of their data (10 points, 1243-1298 K) using auxiliary JANAF data (4) yields the following values for $\Delta_f H°(298.15\ K)$; 36.9±1.6 kcal mol^{-1} (2nd law) and 28.5±0.8 kcal mol^{-1} (3rd law) with a very large drift of -12.85±2.42 cal K^{-1} mol^{-1}. The large drift probably indicates an experimental problem such as lack of equilibrium or the presence of side reactions. Other studies on the enthalpy of formation are summarized by Rao and Dadape (3) and are not considered here since the uncertainties in these studies are very large.

Heat Capacity and Entropy

The 18 observed band systems of NiCl(g) are adequately summarized by Suchard (5). All of these systems have been observed in emission only and the electronic states giving rise to these transitions have not been assigned. The only rotational analysis by Rao and Rao (6) indicates that the upper and lower states are $^2\Delta_{5/2}$ states but the lower state is not definitely identified with the ground state. In view of these difficulties we have chosen to use the electronic energy levels and quantum weights of $Ni^+(g)$ (7) as an approximation to those of NiCl(g). This approximation generally gives upper limit values for the thermal functions; we estimate an uncertainty of ±3 cal K^{-1} mol^{-1} for S°(298.15 K).

Molecular constant data for the ground state are assigned assuming that the lower state of the G band system represents the ground state (5, 6). While this assignment is not certain, the molecular constant data for most of the observed systems are fairly similar (5) so no gross errors will be introduced if this assignment proves incorrect. On this basis the adopted values of B_e and ω_e are from Rao and Rao (6) and Rao et al. (8), respectively, while $\omega_e x_e$ and α_e are our best estimates.

CHLORINE OXIDE (ClO) IDEAL GAS M_r = 51.4524

$S°(298.15\ K) = 226.648\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 101.30 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 101.22 \pm 2.1\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^2\Pi_{3/2}$	0	4

$\omega_e = 866 \pm 26\ cm^{-1}$ $\omega_e x_e = 7.5\ cm^{-1}$ $\sigma = 1$

$B_e = 0.643(3)$ $\alpha_e = [0.0069]\ cm^{-1}$ $D_e = 2.(2) \times 10^{-6}\ cm^{-1}$ $r_e = 1.546$ Å

Enthalpy of Formation

Durie and Ramsay (1) and Herzberg and Ramsay (2) report $D_0^0 = 22152 \pm 10\ cm^{-1}$ and $D_0^0 = 22141\ cm^{-1}$ respectively, and these values have been averaged.

Heat Capacity and Entropy

The spectroscopic constants are for the natural mixture of isotopes and are based on measurements by Durie and Ramsay (1) and by Porter (3). α_e has been estimated by the method given by Herzberg (4).

[490](1)

Ground State Quantum Weight: [2] $\sigma = 1$

Point Group: $[C_{\infty v}]$

Bond Distances: O-Ti = [1.62] Å Ti-Cl = [2.17] Å

Bond Angle: O-Ti-Cl = [180]°

Rotational Constant: B_0 = [0.092252] cm^{-1}

Enthalpy of Formation

$\Delta_f H°$(TiOCl, g, 298.15 K) is calculated from an estimated value of $\Delta_f H°$((TiOCl, g, 0 K) = -58 kcal mol^{-1} (1).

Heat Capacity and Entropy

Molecular constants were estimated by Gordon (1).

Enthalpy of Formation

Evans et al. (1) have evaluated the available data and chosen the above value.

Heat Capacity and Entropy

Gordon (2) has calculated the thermodynamic functions from 298.15 to 6000 K by the method of Pennington and Kobe (3) which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from Coon and Ortiz (4). The functions below 298.15 K have been calculated for a rigidly rotating harmonic oscillator.

$\omega_e = [472]\ cm^{-1}$ $\omega_e x_e = [1.89]\ cm^{-1}$ $\sigma = 1$
$B_e = [0.2443]\ cm^{-1}$ $\alpha_e = [0.00098]\ cm^{-1}$ $r_e = [2.04]$ Å

Enthalpy of Formation

The selected $\Delta_f H°(298.15\ K)$ was calculated by assuming that the second and third bonds in $PCl_3(g)$ are of equal strength, and that the first bond has a strength 20% greater than the other two. These assumptions wee used by Henderson and Scheffee (1). The selected $\Delta_f H°(298.15\ K)$ was calculated using these bond strengths and auxiliary data from JANAF Tables.

A $\Delta_f H°(298.15\ K)$ = 40 kcal mol^{-1} was estimated by O'Brien and Perrin (2).

Sandoval et al. (3) have calculated a $\Delta_f H°(298.15\ K)$ for PCl from an appearance potential. They selected the process $PCl_3 + Cl^+ + e^- + PCl + Cl$ to explain this potential rather than the process $PCl_3 + Cl^+ + e^- + P + Cl_2$. The reason for their selection was a calculated $\Delta_f H°+(Cl)$, 10 kcal mol^{-1} lower than the literature value (See Nat. Bur. Stand., Circ 500). Use of the JANAF $\Delta_f H°(298.15\ K)$ for PCl_3 eliminates this difference. Therefore, the process of the reported appearance potential would apparently be the second process which does not involve the neutral PCl radial.

Heat Capacity and Entropy

The molecular constants were estimated by Gordon (4).

$S°(298.15\ K) = 259.61 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 16.74 \pm 50.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 15.06 \pm 50.2\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$X\ ^2\Pi_{1/2}$	0	2
$^2\Pi_{3/2}$	8274	2
$A[^2\Sigma]$	21866.9	[2]
$B\ ^2\Sigma^+$	34937.5	2

$\omega_e = 302.5\ cm^{-1}$ $\omega_e x_e = 0.88\ cm^{-1}$ $\sigma = 1$
$B_e = 0.1172\ cm^{-1}$ $\alpha_e = [0.00047]\ cm^{-1}$ $r_e = 2.180$ Å

Enthalpy of Formation

$\Delta_f H°(0\ K)$ is obtained from $D_0^0(Pb-Cl) = 3.1 \pm 0.5$ eV (71.5 kcal mol^{-1}) which is the recommended value given by Gaydon (1). D_0^0 is combined with $\Delta_f H°(Pb, g, 0\ K) = 46.91 \pm 0.13$ kcal mol^{-1} and $\Delta_f H°(Cl, g, 0\ K) = 28.587 \pm 0.002$ kcal mol^{-1} (2) to give $\Delta_f H°(PbCl, g, 0\ K) = 4.0 \pm 12.0$ kcal mol^{-1}. $\Delta_f H°$ at 298.15 K is 3.6 ± 12.0 kcal mol^{-1}. The recommended value for D_0^0 is based mainly on results ($(D_0^0(LBX) = 3.2$ eV) of a linear Birge-Sponer extrapolation of the observed vibrational levels (v, 0-18) (3) for the ground state of PbCl. This same value for $D_0^0(LBX)$ is obtained from the results of two other spectrometric studies (4, 5), while the results of another similar study (6) lead to $D_0^0(LBX) = 2.7$ eV. The values of $D_0^0(LBX)$ are increased by only 0.1 eV when corrected for the ionic character of PbCl by application of the Hildenbrand formula (7). Other spectroscopic values for $D_0^0(LBS)$ based on linear Birge-Sponer extrapolations include 2.2 eV ($A^2\Sigma$, or $^2\Delta$) (5) and 2.4 eV ($B^2\Sigma$) (6). The dissociation products are assumed to be $Pb(^1D) + Cl(^2P)(A^2\Sigma$, or $^2\Delta)$ and $Pb(^3P) + Cl(^2P)\ (B^2\Sigma)$. Also, Wieland and Newburgh (8) first reported $D_0^0 = 3.12$ eV from observations of predissociation, but later work (9) gave 3.05, or possibly 3.40 eV. It is to be noted that our $\Delta_f H°$ values for PbCl and $PbCl_2$ (2) indicate no significant differences in the binding of these two molecules. The difference $D_0^0(PbCl-Cl)-D_0^0(Pb-Cl)$ is equal to only 2.2 kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational constants, electronic states (except for $A^2\Sigma$), and levels are taken from the compilation of Rosen (10) for $Pb^{35}Cl$. The vibrational constants are adjusted for the natural isotopic abundances of chlorine. It is not clear whether the first excited state for PbCl is $^2\Sigma$ or $^2\Delta$. By analogy with that for PbF (11), we assume the first excited state to be $^2\Sigma$. However, if this state is $^2\Delta$, the entropy is increased by only 0.006 cal $K^{-1}\ mol^{-1}$ at 4000 K and 0.05 cal $K^{-1}\ mol^{-1}$ at 6000 K. The rotational constant is taken from the results of a rotational analysis of two bands of the A-X system for $^{208}Pb^{35}Cl$ by Singh and Singh (12). The rotational constant is adjusted for the natural isotopic abundances of lead and chlorine. The value for r_e is obtained from the adopted B_e value. The results of an earlier rotational analysis of the same bands by Rao and Rao (13) are in reasonable agreement with our adopted values. The value for α_e is estimated from the other constants assuming a Morse potential function.

Lead Chloride (PbCl) $Cl_1Pb_1(g)$

$S°(298.15\ K) = [255.15 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 741.0 \pm 50.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [745.589]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1
$^3\Pi$	[30000]	6

$\omega_e = [283]\ cm^{-1}$ $\omega_e x_e = [0.82]\ cm^{-1}$ $\sigma = 1$

$B_e = [0.1062]\ cm^{-1}$ $\alpha_e = [0.00043]\ cm^{-1}$ $r_e = [2.29]$ Å

Enthalpy of Formation

The $PbCl^+$ ion has been observed in several mass spectrometric studies (1-4) of the vapors in equilibrium with both solid and liquid $PbCl_2$. Electric deflection experiments of mass spectrometrically detected $PbCl_2$ beams by Buchler et al. (5) have shown neutral $PbCl_2$ to be the precursor of the ion. Reported values for the AP of $PbCl^+$ are 11.7 (1) and 10.7 cal K^{-1} mol^{-1} (2, 3, 4). The higher value of AP was obtained by the method of linear extrapolation; thus, it is judged to be somewhat less reliable. Also, the lower value was obtained with more sensitive equipment. Therefore, we adopt AP = 10.7±0.5 cal K^{-1} mol^{-1} for the process $PbCl_2(g) + e^- \rightarrow PbCl^+(g) + Cl(g) + 2e^-$, and we calculate $\Delta_f H°(PbCl^+, g, 0\ K) = 177.1 \pm 12.0$ kcal mol^{-1} by combining the value for AP with $\Delta_f H°(PbCl_2, g, 0\ K) = -41.1 \pm 0.3$ kcal mol^{-1} and $\Delta_f H°(Cl, g, 0\ K) = 28.587 \pm 0.002$ kcal mol^{-1} (6). $\Delta_f H°$ at 298.15 K is 178.2 kcal mol^{-1}, and the corresponding IP for PbCl is 7.5±1.0 cal K^{-1} mol^{-1}. Our adopted $\Delta_f H°$ is considered a maximum value, since unknown kinetic energy factors could have been involved in the dissociative ionization of $PbCl_2$.

Heat Capacity and Entropy

The dissociation energy of $PbCl^+$ (D_0^0 = 69.5 kcal mol^{-1}) is slightly less than that for PbCl (D_0^0 = 71.5 kcal mol^{-1}). This implies that somewhat weaker binding occurs in the ion relative to the neutral molecule. Thus, one might expect $r_e(PbCl^+, g) > r_e(PbCl, g)$. We assume an increase in r_e of 5% and obtain $r_e(PbCl^+) = 2.29$ Å with $r_e(PbCl) = 2.180$ Å (6). The value of B_e is obtained from the estimated value for r_e. Values for ω_e and $\omega_e x_e$ are estimated by a procedure similar to that given for SrF^+ (6). The constant term (d_{ij}) used in Badger's rule (7) is based on molecular data for PbCl, PbS, CsCl, and BaCl (6). The value of α_e is obtained from the other constants assuming a Morse potential function.

$PbCl^+$ has 10 valence electrons and is isoelectronic with the Group III A monochlorides. By analogy with the electronic states and levels for these isoelectronic molecules (6, 8), we estimate the ground state configuration to be $^1\Sigma$ with a triplet level lying at 30,000 cm^{-1}. The uncertainty in the latter value is believed to be no greater than 5000 cm^{-1}. If the triplet level is decreased to 25,000 cm^{-1}, the entropy increases only 0.01 cal K^{-1} mol^{-1} at 4000 K and 1.14 cal K^{-1} mol^{-1} at 6000 K. The enthalpy at 0 K is -2.357 kcal mol^{-1}.

Enthalpy of Formation

The adopted results are $\Delta_f H°(SCl, g, 298.15\ K) = 37.2 \pm 4.0$ kcal mol^{-1} and $D_0^0(S-Cl) = 57.1 \pm 4.0$ kcal mol^{-1}. We calculate $\Delta_f H°$ from an estimated value for the primary bond dissociation energy of SCl_2 of 69.7 ± 3.0 kcal mol^{-1}, using auxiliary heat of formation data from JANAF (1). The value of $D_0^0(SCl-Cl)$ is obtained from the relationship $D_0^0(SCl-Cl)/\Delta_{at}H°(SCl_2) = 0.55 \pm 0.03$ with $\Delta_a H°(SCl_2) = 126.8 \pm 0.9$ kcal mol^{-1} (1). *The value of the ratio is taken to be the mean of three values calculated (1) for SF_2(0.53±0.05), $SiCl_2$(0.57±0.01), and SiF_2(0.54±0.03).* Converting $\Delta_f H°$ to 298.15 K, we obtain $\Delta_f H°(SCl, g, 298.15\ K) = 37.4$ kcal mol^{-1} which is in reasonable agreement with the previous estimate made by Mills (35±5, 2), McBride et al. (32.0, 3), and Benson (36.5±2, 4).

Perona et al. (5) have measured the hydrogen chloride infrared emission from reactions involving H and D atoms with SCl_2. From the observed highest vibrational level of HCl, they estimated an upper limit to $D_0^0(SCl-Cl)$ of ≤ 58 kcal mol^{-1}. From this result, we calculate $\Delta_f H°(SCl, g, 0\ K) \lesssim 25.5$ kcal mol^{-1} and $D_0^0(SCl) \gtrsim 68.8$ kcal mol^{-1}. We note that the results from this study predict that $D_0^0(S-Cl) > D_0^0(SCl-Cl)$ which is inconsistent with established trends in the bond dissociation energies (1) for other mono- and dihalides, such as the silicon chlorides, silicon fluorides, and sulfur fluorides. Factors which can influence the D_0^0 values estimated from infrared chemiluminescence studies have been discussed by Perona et al. (5). It seems likely that their estimate of D° may be too low due to the formation of some HCl in higher vibrational levels by an energy exchange mechanism rather than what is actually produced by the H/SCl_2 chemical reaction. For these reasons, we believe that the $\Delta_f H°(0\ K)$ value (19±3 kcal mol^{-1} recently reported by Takacs (6) based primarily on his analysis of the chemiluminscence work of Perona et al. (5) is suspect. The results *adopted here predict $D_0^0(SCl-Cl) > D_0^0(S-Cl)$ by roughly 13 kcal mol^{-1} which seems reasonable by comparison with bond energy data (1)* for other halide systems.

Heat Capacity and Entropy

We estimate the S-Cl bond length to lie between those for SCl_2 and S_2Cl_2 (1). The value of B_e is calculated from the adopted r_e. We use Badger's rule (7) to estimate a value for ω_e. The equation is written as $\omega_e^2 = 3.159 \times 10^6/\mu(r_e - d_{ij})^3$, and we use molecular data (1) for SiCl to determine the constant $d_{ij} = 1.172$. The value of x_e is estimated from the expression $x_e \mu^{1/2} = 0.01595$ calculated from data for SiCl (1). By analogy with SiCl, SiF, and SF, we expect the ground state electronic configuration for SCl to be $^2\pi$. The ground state splitting (400 cm^{-1}) and double pi state at 25000 cm^{-1} are estimated from those observed for SF (1).

McBride et al. (3) have previously estimated thermal functions over an extended temperature range (0-6000 K), using molecular data similar to ours. Their entropies are consistently higher than our values by 0.6 cal K^{-1} mol^{-1} at 298.15 K and 0.3 cal K^{-1} mol^{-1} at 4000 K. The difference at 298.15 K arises primarily from the electronic contribution caused by treating the ground state as a single level (3) with a quantum weight of 4. We believe that the uncertainty in S°(298.15 K) should not exceed ±0.6 cal K^{-1} mol^{-1}. Their estimate of $\omega_e x_e = 5.85\ cm^{-1}$ (3), obtained assuming a linear Birge-Sponer relation, seems rather high in comparison with similar data (1) for SiCl, SiF, and SF.

Enthalpy of Formation

Blais and Cottin (1) have measured the appearance potential (AP) of $SCl^+(g)$ from $SCl_2(g)$ as 12.5±0.2 eV using the electron impact technique. Subsequent work by Hartmann et al. (2) using the same method led to $AP(SCl^+/SCl_2)$ = 12.2±0.1 eV which confirms the earlier results. We assume that the fragment ions produced in the dissociative ionization process $e^- + SCl_2(g) = SCl^+(g) + Cl(g) + 2\ e^-$ are formed with no excitation energy or excess kinetic energy, and we calculate the adopted value of $\Delta_f H°(0\ K)$ = 252.3±5.0 kcal mol^{-1} by combining the mean value (284.795 kcal mol^{-1}) of these two AP's with $\Delta_f H°$ data (3) for Cl(g) and $SCl_2(g)$.

Blais and Cottin (1) have also reported the electron impact AP for $SCl^+(g)$ from $S_2Cl_2(g)$ as 13.6±0.2 eV. Assuming that the ionization process is $e^- + S_2Cl_2(g) = SCl^+(g) + SCl(g) + 2e^-$, their AP value gives $\Delta_f H°(SCl^+, g, 0\ K)$ = 272.8 kcal mol^{-1} which is about 20 kcal mol^{-1} higher than the adopted value. Comparison of JANAF IPs (3) for SF (10.09±0.1 eV), SF_2 (10.29±0.3 eV), and SCl_2 (9.46±0.02 eV) suggests that the ionization value for SCl should lie near 9.3 eV. Our adopted data for SCl(g) and $SCl^+(g)$ give IP(SCl) = 9.33±0.4 eV. The higher $\Delta_f H°$ value of 272.8 kcal mol^{-1} corresponds to IP(SCl) = 10.2 ev which appears to be too high by comparison with the difference in the IPs for SF and SF_2 and the highly reliable IP value for SCl_2(3).

$\Delta_f H°(298.15\ K)$ is obtained from the adopted $\Delta_f H°(0\ K)$ value by using JANAF enthalpies $H°(0\ K) - H°(298.15\ K)$ (3) for S(α, cr), $Cl_2(g)$, and $e^-(g)$. $\Delta_r H°(298.15\ K)$ determined for the direct ionization $SCl = SCl^+ + e^-$ from our tables differs from a room-temperature threshold energy due to inclusion of the enthalpies of all the species in this ionization process and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by −1.481 kcal mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron. The S-Cl bond strength to form $S^+(g)$ and Cl(g) by dissociation is calculated to be 80.8±5.0 kcal mol^{-1}.

Heat Capacity and Entropy

The value of r_e has been selected such that when it is substituted into the equation for Badger's rule (5) written as $\omega_e^2 = 3.159 \times 10^6/\mu(r_e - d_{ij})^3$, a value of ω_e(553 cm^{-1}) is obtained which agrees with that (552.3 cm^{-1}) determined for $P^{35}Cl$ by Coxon and Wickramaaratchi (6). The value of d_{ij} is taken equal to 1.10 based on the molecular data for SiCl(3) and $P^{35}Cl$ (6). This procedure gives r_e = 1.95 Å which is only slightly lower than the S-Cl bond lengths (3) measured for SCl_2(2.015 Å) and S_2Cl_2(2.057 Å). We calculate B_e from the estimated value of r_e. Using the expression $x_e\mu^{1/2} = 0.01623$, x_3 is determined to be 0.00396 which gives $\omega_e x_e$ = 2.19 cm^{-1} when multiplied by the estimated value of ω_e. The value of the constant in the above expression is based on the values determined for SiCl and PCl. The value of α_e is determined from the other estimated molecular constants assuming a Morse potential function.

Examination of the electronic configurations and levels for diatomic halides having 12 valence electrons, such as PF (3) PCl (6), NCl, and NF (7) suggests that the ground state for SCl^+ is most likely $^3\Sigma$, and several low-lying excited states are expected. We estimate the relative term value for the $a^1\Delta$ state from that observed for PF (7090.41 cm^{-1}). Relative term values for the $b^1\Sigma$ and $A^3\Pi_r$ states are estimated by analogy with those observed for PCl (6). As discussed by Coxon and Wickramaaratchi (6) for PCl, other singlet ($^1\Pi$) and triplet ($^3\Pi_i$ and $^3\Sigma$) states may be expected to lie in the range 20000 - 35000 cm^{-1}, similar to those observed for the isoelectronic molecules O_2, S_2, and SO (3). Inclusion of estimated term values for these additional levels changes our entropy by only about 0.05 cal K^{-1} mol^{-1} at 4500 K, and we prefer to omit these levels at this time. The adopted electronic entropy contribution from the excited states amounts to 0.01 cal K^{-1} mol^{-1} at 1500 K, and this contribution increases to 0.51 cal K^{-1} mol^{-1} at 4500 K.

Point Group: $[C_s]$ σ = [1]

Bond Distances: S-Cl = [2.00] Å

S-S = [1.90] Å

Bond Angle: S-S-Cl = 105°

Product of Moments of Inertia: $I_A I_B I_C = [4.34028 \times 10^{-114}]\ g^3\ cm^6$

Enthalpy of Formation

Perona et al. (1) have studied the infrared emission from vibrationally excited HCl and DCl formed in the reaction of H and D atoms on S_2Cl_2. From their observation that the highest HCl vibrational level occupied was $v = 7$, they obtained an upper limit estimate of the first bond dissociation energy for S_2Cl_2 of D_0^0 (S2Cl-Cl) $\lesssim$ 53 kcal mol^{-1}. Combining this value with $\Delta_f H°$ data for gaseous Cl and S_2Cl_2 (2), we calculate that $\Delta_f H°(S_2Cl, g) \gtrsim 20.8$ kcal mol^{-1}. A recent independent analysis of these thermochemical data for S_2Cl_2/S_2Cl was made by Takacs (3) who reported $\Delta_f H°(S_2Cl, g, 0\ K) = 17 \pm 2$ kcal mol^{-1} based on slightly different auxiliary $\Delta_f H$ datum for S_2Cl_2 (-7.7 kcal mol^{-1}) than what (-3.6 kcal mol^{-1}) was used here. In the same paper, Perona et al. (1) also used the infrared chemiluminescence technique to measure bond dissociation energies for Cl_2 and the first S-Cl bond in SCl_2. While this technique leads to results in accord with the known thermochemistry of Cl_2/Cl (2), it appears to give biased results in the case of SCl_2 (see SCl(g) table for discussion). Factors which can adversely influence the D_0^0 values determined from infrared chemiluminescence studies have been discussed by Perona et al. (1).

In a recent review of the thermochemistry of sulfur-containing species, Benson (4) has shown that in R_2S_2 compounds with R equal to H, alkyl, or aryl the first R-S bond dissociation energy exceeds the second one by 9.5 ± 1.0 kcal mol^{-1}. Assuming this same trend holds for R=Cl, we obtain $\Delta_r H° = 9.5$ kcal mol^{-1} for $S_2Cl_2(g) + S_2(g) = 2\ S_2Cl(g)$ which leads to $\Delta_f H°(S_2Cl, g, 0\ K) = 18.3 \pm 1.0$ kcal mol^{-1} by combining the value of $\Delta_r H°$ with JANAF $\Delta_f H°$ values for S_2Cl_2 and S_2 (2).

We choose to adopt a $\Delta_f H°$ value of 19.0±2.0 kcal mol^{-1} which is a weighted average of the two results derived above. The values of $\Delta_f H°$ at 298.15 K and of $\Delta_{at} H°(0\ K)$ are 18.8±2.0 kcal mol^{-1} and 140.9 ± 2.0 kcal mol^{-1}, respectively. Using JANAF data (2), we find bond dissociation energies in the S_2Cl radical are $D_0^0(S_2\text{-}Cl) = 40.2$ kcal mol^{-1} and D_0^0(S-SCl) = 83.9 kcal mol^{-1}.

Heat Capacity and Entropy

S_2Cl has 19 valence electrons, and according to the Walsh correlation diagram (5), the radical should have a bent structure with a bond angle somewhat greater than that (102°, 2) found for the 20 valence electron molecule SCl_2. We adopt a Cl-S-S angle of 105° which is intermediate between the measured angles for SCl_2 and S_2Cl_2(2). CNDO and INDO calculations (6) on S_2Cl as a function of bond angle show an energy minimum at 100°, supporting our adopted value. The S-Cl and S-S bond distances are estimated from experimentally measured structural data (2) for S_2Cl_2, SCl_2, and S_2. The principal moments of inertia are: $I_A = 5.0613 \times 10^{-39}$, $I_B = 26.8624 \times 10^{-39}$, and $I_C = 31.9237 \times 10^{-39}$ g cm^2.

Wight and Andrews (7) have observed an absorption band system at 21930-26178 cm^{-1} during mercury are photolysis of Ar/S_2Cl_2 matrices and alkali metal S_2Cl_2 matrix reactions. They assigned this band system to S_2Cl and suggested that the S-Cl stretching frequency was $\geq$ 490 cm^{-1} based on the observed vibrational spacing in the absorption spectrum. We estimate ν_1 = 500 cm^{-1} based on the S-Cl stretching frequencies for S_2Cl_2 (466 and 461 cm^{-1}, 2), SCl_2(528 cm^{-1}, 2), and SCl_2^+ (530±30 cm^{-1}, 8). The ν_2 bending and ν_3 S-S stretching frequencies are estimated by similar comparisons to that for ν_1. The value of ν_3 is chosen to lie between those (2, 9) observed for S_2Cl_2 (546 cm^{-1}) and S_3(590 cm^{-1}).

An absorption band system has been observed at 22000-26000 cm^{-1} when gaseous S_2Cl_2 is flash photolyzed (10, 11), when Ar/S_2Cl_2 matrices are mercury arc photolyzed during deposition (7), and when S_2Cl_2 is reacted with alkali metal atoms in argon matrices (7). Wight and Andrews (7), along with McGrath (10), have assigned this spectrum to the S_2Cl radical while Donovan et al. (11) believe that portions of the spectrum are due to SCl and S_3. In addition, Donovan et al. (11) observed during flash photolysis of S_2Cl_2 a number of transient bands in the region 30221-34200 cm^{-1} which may be due to S_2Cl. By analogy with the known electronic levels for the isoelectronic radical cations SCl_2^+, OCl_2^+, and OF_2^+ (12), we predict the existence of three excited states for S_2Cl which should give rise to transitions from the ground state in the 20000-30000 cm^{-1} region. No attempt is made here to make definite assignments for the observed absorption spectra (7, 10, and 11) assigned to S_2Cl since this will require the results of higher resolution experiments. We prefer to predict the electronic configurations for the ground and excited states from the Walsh correlation diagram (5) and to estimate their relative term values based on the vertical ionization potentials (8, 12) observed in the photoelectron spectra of SCl_2, OCl_2, and OF_2. A detailed description of the factors considered in making these estimates can be found on the SF_2^+ gas table (2).

Additional support for the existence of the S_2Cl radical is provided by the matrix photolysis work of Herring et al. (6).

Enthalpy of Formation

The adopted value is based upon a 3rd law analysis of effusion mass spectrometric data by Farber (1) who obtained $\Delta_r H°$ (298.15 K) = 27.1 kcal mol^{-1} for $Si(g) + SiCl_2(g) = 2\ SiCl(g)$. *With auxiliary JANAF data (2) this yields* $\Delta_f H°(298.15\ K) = 47.4 \pm 1.6$ kcal mol^{-1}. The error estimate is somewhat higher than that given by Farber and should more accurately reflect the uncertainties in relative cross-section values. A value of 88.3±3.0 kcal mol^{-1} is obtained for D_0^0 using auxiliary JANAF data (2). A linear Birge-Sponer extrapolation of the ground state vibrational data (3) yields D_0^0 = 93.8 kcal mol^{-1} in good agreement with the adopted value. Similar extrapolations for other electronic states yield higher values; Gaydon (4) obtained 104±12 kcal mol^{-1} from the B' $^2\Delta$ state. The value of D_0^0 may be compared to the average *(per bond) enthalpies of atomization of 94.7, 96, and 101.9 kcal* mol^{-1} for $SiCl_4$, $SiCl_3$, and $SiCl_2$, respectively (2).

Heat Capacity and Entropy

Vibrational and rotational constants and splitting for the ground state are taken from the analysis of the A-X system by Singhal and Verma (3). These are in excellent agreement with those of several other investigators (5-10, 12, 13, 15). Spectroscopic information for the A $^2\Sigma$ state is also taken from Singhal and Verma (3) and yields different molecular constants than an earlier study by Sanii and Verma (5). Molecular constants for the B $^2\Sigma$ state are taken from Ovcharenko (6) and Rai (7) and show good agreement with those of Ovcharenko (8) and Mishra (9). The molecular constants for the B' $^2\Delta$ state are taken from Verma (10) and are in good agreement with the less precise measurements by Ovcharenko (11). The vibrational properties of the C $^2\pi$ state were taken from Jevons (12) while the rotational constants are from Pandley (13). The latter differ slightly from those of Ovcharenko (14). The spin splittings of 2.727 cm^{-1} (10) and 10-12 cm^{-1} (13, 14) for the B' and C states, respectively, have been ignored in our calculations. The vibrational constants for the D $^2\Pi$ state were taken from Oldershaw (15); since no rotational study is available, we have used the ground state B_e and α_e as first approximations in our calculations. This introduces a nearly negligible error in the thermal functions. Oldershaw (15) has observed two additional sets of high energy levels but these are not included due to uncertainties in their states. It should be recognized that the $^4\Sigma^-$ state observed for SiF and SiI (2) has not been discovered for SiCl; by analogy with SiF and SiI it is expected to lie at 26,000±3,000 cm^{-1}. The stated uncertainty in the entropy should account for this level as well as the splittings mentioned above. The ground state is treated as two distinct levels due to the splitting of this state as expressed by the spin coupling constant (A = 207.2 cm^{-1}). This leads to slightly biased results at low temperatures (below 500 K); the stated uncertainty in S°(298.15 K) should account for this also. All molecular constant data has been corrected to reflect the natural isotopic abundances of Si and Cl.

Enthalpy of Formation

$\Delta_f H°$ is a weighted average of results from three gas-phase equilibrium reactions studied mass spectrometrically by Hildenbrand (1) and Potter et al. (2). Analyses of these data are summarized below. The overall range of values is less than 4 kcal mol^{-1}, suggesting the approximate uncertainty in $\Delta_f H°$. From the adopted $\Delta_f H°$ we calculate D_0^0 = 98.2±2 kcal mol^{-1}. Independent methods give 98±4 (3), ≥ 99 (4), 95.6±1.6 (5), 97±6 (6) and 88.1 kcal mol^{-1} (7).

Electron-impact data (3) gave D_0^0(ClSr-Cl) = 112.8±3.3 and we use $\Delta_{at}H°(SrCl_2)$ = 210.8±3 kcal mol^{-1} to derive D_0^0 = 98±4 kcal mol^{-1}. Chemiluminescence from crossed beams of Sr atoms with Cl_2 gave an approximate lower limit of 99 kcal mol^{-1} (4). Flame studies gave D_0^0 = 95.6±1.6 kcal mol^{-1} (5) and D_0^0(ClSr-Cl) = 114±5 kcal mol^{-1} (6); we derive D_0^0 = 97±6 kcal mol^{-1} from the latter value using $\Delta_{at}H°(SrCl_2)$ = 210.8±3 kcal mol^{-1}. Ryabova et al. (6, 5) considered the flames to involve $SrCl_2$, SrOHCl and SrOH as well as SrCl. Schofield and Sugden (8) inferred that the flames involved mainly $SrCl_2$ rather than SrCl as assumed in earlier flame studies. Gaydon (9) discounted a value of D_0^0 derived from limited spectroscopic data on the ground state. Novikov and Gurvich (7) published additional emission spectra and derived D_0^0 = 88.1 kcal mol^{-1} by parabolic extrapolation. This value should be considered as approximate in light of Gaydon's precautionary notes, especially since the observed levels extend only to about 0.3 of the dissociation limit. Hildenbrand (1) found that ionicity corrections bring the Birge-Sponer extrapolation into reasonable agreement with D_0^0.

(1) Hildenbrand (1970)	C	1661		2.07±2		-30.72±3.6	99.6

Reactions: (A) Sr(g) + $SrCl_2$(g) = 2SrCl(g); (B) Sr(g) + AlCl(g) = SrCl(g) + Al(g); (C) Ca(g) + SrCl(g) = CaCl(g) + Sr(g).

Heat Capacity and Entropy

Electronic levels and vibrational constants are based on the review of Rosen (10) as modified by the additional data of Novikov and Gurvich (7). Vibrational constants are adjusted for natural isotopic abundances. B_e is calculated from r_e which is estimated by comparison of the bond lengths of MX_2(M=Mg, Ca, Sr, Ba and X=F, Cl) with those of MgCl, CaCl and MF(M=Mg, Ca, Sr, Ba). The value of α_e is estimated from the Morse potential function.

Titanium Chloride (TiCl) $Cl_1Ti_1(g)$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(298.15\ K)$, of TiCl(g) is calculated from the dissociation energy which is estimated as 105 kcal mol^{-1}. This estimate is obtained from the relation $D(TiCl_4) < D_0^0(TiCl) < D(TiCl_3)$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of $TiF_2(g)$ by Zmbov and Margrave (1).

Extrapolations of the vibrational levels reported by Shenyavskaya (2), Rao (3) and Mace and Packer (4) yield values of the dissociation energy which are very low with respect to bond energy relations.

Heat Capacity and Entropy

The vibrational frequency, ω_e, and anharmonic vibrational term, $\omega_e x_e$, were reported by Shenyavskaya et al. (2). The interatomic distance is estimated from Guggenheimer's relation (5). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+ (6). α_e is estimated from the Morse potential function.

$B_e = [0.11105]\ cm^{-1}$ $\alpha_e = [0.00042]\ cm^{-1}$ $r_e = [2.26]$ Å

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WCl, g, 298.15\ K) = 132.3\ kcal\ mol^{-1}$, is calculated from the bond dissociation energy, $D_0^0(W-Cl, 298.15\ K) = 100 \pm 10\ kcal\ mol^{-1}$. This estimated $\Delta_{at}H°(298.15\ K)$ is obtained from the average bond dissociation energy for $WCl_x(g) + W(g) + xCl(g)$ where x = 2,4,5,6, using all JANAF values.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in $WCl_6(g)$. This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency ω_e (1). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D° + 0.5\ \omega_e) = 0.0032$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for WF(g) (2).

Enthalpy of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl, $ZrCl_2$, $ZrCl_3$ and $ZrCl_4$. Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction $ZrCl_3(g) + ZrCl(g) = 2\ ZrCl_2(g)$ in the temperature range 1978-2274 K, 2nd and 3rd law analyses give the enthalpies of reaction at 298 K as -10.36 and -12.83 kcal mol^{-1}, respectively. The 3rd law drift is 1.4 ± 2.5 cal K^{-1} mol^{-1}. Based on the 3rd law $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(ZrCl_2, g, 298.15\ K)$ = -44.5 kcal mol^{-1} (2) and $\Delta_f H°(ZrCl_3, g, 298.15\ K)$ = -125.3 kcal mol^{-1} (3), we obtain $\Delta_f H°(ZrCl, g, 298.15\ K)$ = 49.1 kcal mol^{-1} *which is adopted in the tabulation.*

Farber et al. (4) also studied mass spectrometrically the reaction Zr(cr) + Cl(g) → ZnCl(g). The reported a second law heat of reaction $\Delta_r H°(298.15\ K)$ = 8.7 ± 1.4 kcal mol^{-1}. Using the equilibrium constants K = I(ZrCl)/I(Cl) which we calculated from their reported ion intensities of run 3 in the temperature range 1667-1896 K, we obtain $\Delta_r H°(298.15\ K)$ = 20.3 kcal mol^{-1} by the 3rd law method. The 3rd law drift is 6.1 ± 2.4 cal K^{-1} mol^{-1}. The enthalpy of formation is derived as $\Delta_f H°(ZrCl, g, 298.15\ K)$ = 49.2 kcal mol^{-1}.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in $ZrCl_4(g)$. The bond distance is then used with Guggenheimer's relation (5) for polar molecules to calculate the fundamental vibrational frequency ω_e. The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D° + 0.5\ \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function.

The ground state configuration is taken from the ground state multiplet of Zr^+ reported by Moore (6). The electronic levels and the quantum weights are estimated to be the same as those of ZrF(g).

(f) The dissociation energy of each state is relative to the lowest level of the ground state.

Enthalpy of Formation

Zero by definition. Refer to the monatomic chlorine gas table for a discussion of the dissociation energy.

Heat Capacity and Entropy

The thermal functions are calculated using a direct summation technique. Included in the calculation are the ground state plus the $^3\Pi_0^+$ excited state at T_e = 17833 cm^{-1}. To account, in an approximate way, for the presence of the $^3\Pi_0^-$, $^3\Pi_{1u}$, and $^3\Pi_{2u}$ excited states (all near T_e = 17000 cm^{-1}) the rotational states of the $^3\Pi_0^+$ state are artificially weighted by a factor of six.

For the ground state only, the calculation is performed including the so-called quasi-bound rotational levels above the dissociation limit (4,5). For a given vibrational quantum number, v, the summation over rotational states is carried out up to a rotational quantum number, J, given by $J = J_{lim}(1-v/v_{max})$, where J_{lim} and v_{max} were determined by Gurvich et al. (3) to be 418 and 61, respectively. We adopt the $^{35}Cl_2$ ground state spectroscopic constants and dissociation energy of Douglas and Hoy (1) who gave Dunham type coefficients which fitted the spectroscopic data for v ≤ 40. For 41 ≤ v ≤ 60, we use the exact G_v, B_v, and D_v data as given by Douglas and Hoy (1).

For the $^3\Pi_0^+$ state, we use the spectroscopic constants given in Gurvich et al. (3) as deduced from Clyne and Coxon (6). The excited states contribute significantly to the heat capacity above 3000 K but the effect on the Gibbs free energy function is considerably smaller (amounting to only 0.4 J K^{-1} mol^{-1} at 6000 K). The rotational levels are extrapolated to high J values according to the method of Khachkuruzov (7) who proposed a simpler form of Woolley's method (8).

The spectroscopic constants of the hypothetical natural abundance species are determined from the $^{35}Cl_2$ data using a standard reduced mass scaling routine. Our adopted value for S°(298.15 K) differs by 0.003 J K^{-1} mol^{-1} from values recommended by CODATA (11) and Gurvich et al. (3) and by 0.007 J K^{-1} mol^{-1} from the value recommended by Wagman et al. (9). For this comparison, the values reported by CODATA (11) and Gurvich et al. (3) are increased by 0.1094 J K^{-1} mol^{-1} to account for a change in standard-state pressure from 1 atm to 1 bar.

Phase Data

Hultgren et al. (10) had recommended a triple point of 172.16 K (0.01374 atm) and a boiling point of 239.10 K (1 atm). These values should prove reasonably accurate, although they have not been evaluated by the present authors, and are furnished for the convenience of the reader. As a result of the low values, the reference state for chlorine is chosen to be the ideal diatomic gas at all temperatures.

PREVIOUS: September 1965 (1 atm) CURRENT: June 1982 (1 bar)

$S°(298.15\ K) = 109.265 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1013 \pm 2\ K$

$\Delta_f H°(0\ K) = -314.39 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -312.54 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [44.77 \pm 6.3]\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted value for $\Delta_f H°(298.15\ K)$ of -74.7 kcal mol^{-1} is that given in NBS Technical Note 270-4 (1). This value is based mainly on results derived from heat of solution measurements on Co(cr) (2) and $CoCl_2$(cr) (3) in aqueous HCl, $\Delta_f H°(CoCl_2, cr, 298.15\ K) = -74.9 \pm 1.0$ kcal mol^{-1}, and from a 3rd law analysis of several sets of equilibrium data (4-11). Results of earlier heat of solution measurements on Co(cr) (12, 13) in aqueous HCl are in reasonable agreement (±0.4 kcal mol^{-1}) with those used in our calculations (2), while the results of Thomsen (14) are some 2 kcal mol^{-1} more negative. Results of a 2nd and 3rd law analysis of the equilibrium data with JANAF functions are tabulated below. Auxiliary $\Delta_f H°$ data used in the analysis are (in kcal mol^{-1}): $\Delta_f H°(HCl, g, 298.15\ K) = -22.063 \pm 0.05$ and $\Delta_f H°(FeCl_2, cr, 298.15\ K) = -81.7 \pm 0.1$ (15).

Egan (9)	B	emf	2	673;723	-74.1	-75.09±0.10	-1.5	75.1±0.1
Hamby and Scott (10)	B	emf	1	973		-73.09		73.1
Sheldon and Gee (11)	C	emf	Equation	490-760	-6.4	-7.10±0.22	-1.1±0.02	74.6±0.3

*Reactions: (A) $CoCl_2(cr) + H_2(g) = Co(cr) + 2\ HCl(g)$ (B) $Co(cr) + Cl_2(g) = CoCl_2(cr)$ (C) $Fe(cr) + CoCl_2(cr) = FeCl_2(cr) + Co(cr)$

Three (5-7) of the five sets of equilibrium data on the H_2 reduction of $CoCl_2$(cr) yield $\Delta_f H°$ values which are in good agreement (±0.3 kcal mol^{-1}) with the value (-74.9 kcal mol^{-1}) obtained by solution calorimetry (2, 3). Also, the results obtained from our analysis of the recent emf study of reaction (C) provide further confirmation for the adopted value of $\Delta_f H°$.

Heat Capacity and Entropy

$C_p°$ data below 300 K are based on the low temperature measurements of Chisholm and Stout (16) (11-300 K) and Kostryukova (17) (1.8-4 K). The $C_p°$ data of Kostryakova (17) below 3 K involve bias due to the presence of trace amounts of water in the $CoCl_2$ sample. His results (17) contain a small anomaly near 2.8 K which presumably arises from the $CoCl_2 \cdot 6\ H_2O$ anti-ferromagnetic transition at 2.3 K (18). The effect of the hexahydrate on the $C_p°$ data above 3 K is judged to be negligible. The $C_p°$ data above 3 K are joined graphically with those of Chisholm and Stout at 11 K (16). The latter data set contains a lambda peak at 24.71 K. $C_p°$ near the maximum is 4.1 cal K^{-1} mol^{-1}, and the enthalpy associated with the transition is on the order of a few calories. The existence of this anomaly has been confirmed from heat capacity measurements by Shalyt (19)(30-75 K, T_{trs} = 24.9 K) and Trapeznikowa et al. (20) (13-130 K, T_{trs} = 24.90 K). This anomaly is apparently associated with the cooperative ordering of the magnetic moments of the cobaltous ions. The latter two sets of $C_p°$ data are judged to be less reliable than that of Chisholm and Stout (16) and are not used in the calculation of S°(298.15 K). S°(298.15 K) is obtained from integration of the adopted $C_p°$'s and is based on S°(3 K) = 0.003 cal K^{-1} mol^{-1}.

$C_p°$ data above 300 K are estimated from Cp-T curves for $FeCl_2$ (15) and $MnCl_2$ (21). The results of the only high temperature enthalpy study (22) reported for $CoCl_2$(cr) have been analyzed by Kelley (21). However, a comparison of these $C_p°$'s with those for the isostructural chlorides $FeCl_2$ (15) and $MnCl_2$ (21) indicate that these values are probably too high by 3.5% at 400 K and 27.3% at 1000 K. Other comparisons (21, 15) exist which indicate that it is not unusual for the $C_p°$ data of these Russian workers to be in error by several percent.

PREVIOUS: CURRENT: June 1973

$S°(298.15\ K) = [-149.021]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1013 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-271.514]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [44.8 \pm 6.3\ ]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of the crystal by addition of the estimated value for $\Delta_{fus} H°$ and the difference in enthalpy, H°(1013 K) - H°(298.15 K), between the crystal and liquid. Independent values of $\Delta_f H°(\ell)$ (or $\Delta_f H°(cr)$) can be obtained from a 2nd and 3rd law analysis of two sets (1, 2) of emf data for the formation cell of molten $CoCl_2$. Results of our analysis of these data are tabulated below.

Source	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(\ell)$ kcal mol^{-1}	$\Delta_f H°(cr)$ kcal mol^{-1}
Devoto and Guzzi (1)	4	1023-1173	-75.8	-65.77±1.2	9.2±1.8	-65.8	-75.6
Hamby and Scott (2)	2	1073-1173	-65.9	-63.67±0.3	2.0	-63.7	-73.5

Even though both data sets contain few points and show significant positive drift, we note that the average $\Delta_f H°(cr)$ value (-74.6 kcal mol^{-1}) obtained from these results is in excellent agreement with our adopted value (-74.7 kcal mol^{-1}).

Heat Capacity and Entropy

$C_p°$ is assumed constant at 23.70 cal K^{-1} mol^{-1} in the temperature range 700-2000 K and is estimated from liquid heat capacities (3) for $FeCl_2$, $MgCl_2$, $CaCl_2$ and $NiCl_2$ (4). A glass transition is assumed at 700 K below which $C_p°$ is that of the crystal. S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} is that obtained by Schafer and Krehl (5) from cooling curve measurements. Other reported values for T_{fus} are 997 K (6) and 1008 K (7). Our adopted value for T_{fus} is that selected by Brewer et al. (8), while Kelley (9) chose T_{fus} = 1000 K. $\Delta_{fus} H°$ is calculated from $\Delta_{fus} H° = \Delta_{fus} S° \times T_{fus}$ with $\Delta_{fus} S° = 3.51 \pm 0.5$ cal K^{-1} g-atom^{-1}. $\Delta_{fus} S°$ is estimated from similar data (3, 4) for the isostructural chlorides $FeCl_2$, $MgCl_2$, $MnCl_2$, $NiCl_2$, and $CdCl_2$. Kelley (9) has analyzed freezing point depression data for several binary systems which involve $CoCl_2$. Unfortunately, the values of $\Delta_{fus} H°$ derived by Kelley (9) are very discrepant and probably of no use in defining $\Delta_{fus} H°$. Reported values fall in the range 6.71-8.75 kcal mol^{-1}, and Kelley (9) recommended $\Delta_{fus} H°$ = 7.39 kcal mol^{-1}. This value is 3.31 kcal mol^{-1} less than our estimated value and is also inconsistent with $\Delta_f H°$ values derived for the crystal and liquid from equilibrium data. See Enthalpy of Formation Section for $CoCl_2$(cr, ℓ). The discrepancies which arise in Kelley's analysis of the freezing point data may be associated with the ability of the divalent cobalt ion to form complex ions.

Vaporization Data

See the ideal gas table for details.

Enthalpy of Formation

$\Delta_f H°$ is calculated from $\Delta_{sub}H°$ = 52.3 ± 1.7 kcal mol^{-1} by addition of $\Delta_f H°(CoCl_2, cr, 298.15\ K)$ = -74.7 ± 0.3 kcal mol^{-1} (1). The adopted value for $\Delta_{sub}H°$ is based on results of a 2nd and 3rd law analysis of extensive sublimation data reported by Hill et al. (2). These studies included both Knudsen-effusion and torsion-effusion measurements which were performed in platinum-10% rhodium effusion cells. Orifice diameters of the cells varied from 0.0518 cm to 0.1645 cm. The extent of dimerization (~1-2%) was also determined from mass spectrometric measurements, and the measured vapor pressures were corrected to represent equilibrium pressure of the monomer. Results of our analysis of sixty-four vapor pressure points measured in five different cells are given below. Derived $\Delta_f H$ values show no significant trends with orifice size; thus, a mean value of the five results is adopted. Also included in this table is a value for $\Delta_f H$ which was obtained from an analysis of equilibrium data (3) for CoO(cr) + Cl_2(g) = $CoCl_2$(g) + 1/2 O_2(g). Orlov (3) has not reported sufficient information to allow a small correction to be made for dimerization; even so, his results still give a value for $\Delta_f H°$(-22.1 kcal mol^{-1}) which agrees fairly well with that adopted.

Source	Method	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°$ (298.15 K) kcal mol^{-1}

(3)	Transpiration	1323-1523	Equation	16.6	34.77±2.1	12.7	22.1±2.2(b)

(a)Two points rejected due to failure of a statistical test. (b)$\Delta_f H°$(CoO, cr, 298.15 K) = -56.82 ± 0.10 kcal mol^{-1} (1).

Other vapor pressures for $CoCl_2$(cr, ℓ) have been measured by static (4) and transpiration (5, 6) methods. In all three studies the presence of a small amount of dimer in the saturated vapor was not considered. JANAF pressures based on (a) selected values of the heats of sublimation and vaporization for the monomer and dimer, (b) the mass spectrometric value of $2\Delta_{sub}H$(monomer)- $\Delta_{sub}H$(dimer) = -38.99 kcal mol^{-1} (see Co_2Cl_4(g) table) at 298.15 K, and (c) adopted entropies for the condensed and gaseous species are compared with the observed total pressures in the table given below.

Source	Method	Process	T/K	Mole Fraction Dimer Calc. Range	P_{calc}/P_{obs} Range
(4)	Static	Sublimation	906-997	0.051.0.086	0.073-0.156
(4)	Static	Vaporization	1022-1256	0.082-0.092	0.198-0.816
(5)	Transpiration	Vaporization	1015-1144	0.090-0.092	0.531-0.743
(6)	Transpiration	Sublimation	925-1010	0.057-0.091	0.875-1.096
(6)	Transpiration	Vaporization	1019-1073	0.092	0.825-0.883

Our predictions agree reasonably well with the transpiration data of Schafer and Krehl (6), while the static measurements of Maier (4) show significant deviations from our pressures, particularly at lower temperatures. We note that JANAF analysis (1) of Maier's vapor pressures for $BaCl_2$, $AlCl_3$, and $FeCl_2$ indicate the existence of temperature dependent errors in his measurements; thus, the $CoCl_2$ results are probably not reliable. The transpiration data of Kulkarni and Dadape (5) show similar discrepancies.

Heat Capacity and Entropy

Measurements of the infrared (7-9) and electronic (10-12) spectra of both matrix-isolated and gaseous $CoCl_2$ have been interpreted on the basis of a linear structure of $D_{\infty h}$ symmetry. This structure is adopted, and the Co-Cl bond length is taken to be equal to the value determined by Tremmel et al. (13). The antisymmetric stretching frequency (ν_3) is that observed in the infrared absorption spectra of gaseous CoC_2 by Leroi et al. (7). This value has been confirmed from results of two infrared matrix isolation studies (8, 9). The doubly degenerate bending frequency (ν_2) was observed by Thompson and Carlson (8) in the infrared spectra of $CoCl_2$ isolated in an argon matrix. The infrared-inactive symmetric stretching frequency (ν_1) is estimated by comparison with similar data for $FeCl_2$ (1) and $NiCl_2$ (14). Some additional support for this value is provided by calculations of DeKock and Gruen (11). Assuming linear model, they calculated ν_1 = 332 cm^{-1} from ν_3 = 493 cm^{-1}. Also, Clifton and Gruen (15) observed a vibrational spacing of 332 cm^{-1} in the fluorescence spectrum of argon matrix-isolated $CoCl_2$ which may be ν_1. A similar assignment for $NiCl_2$ was recently proposed (14) based on observations of vibrational spacings in its fluorescence spectrum.

The electronic spectra of $CoCl_2$ have been extensively investigated both in the gas phase (10, 11, 16) and in various matrices (9, 12, 15, 17). Unfortunately, most of the results are conflicting and difficult to interpret. It is not certain whether the ground state configuration is $^4\phi$, or $^4\Sigma$. Theroretical arguments based on a ligand-field model (12, 18) favor the former, but recently Lever and Hollebone (19) interpreted the electronic spectra of $CoCl_2$ in terms of an "orbital angular over-lap" model and preferred the latter ground state configuration. Other problems associated with band assignments in the $CoCl_2$ spectra have been dealt with by Smith (18). The adopted states and levels comprise one of two sets of assignments proposed by Lever and Hollebone (19). The alternate functions derived from their second set of assignments (19) suggest that the adopted entropies may be biased by as much as +2 cal K^{-1} mol^{-1} at 298 K and +0.2 cal K^{-1} mol^{-1} at 4000 K. Functions based on the assignments of Smith (18) agree with those adopted to better than 1 cal K^{-1} mol^{-1} at all temperatures.

Enthalpy of Formation

Datz (1) studied the molecular association equilibrium in cesium chloride vapors by measuring the temperature dependence of the molecular weight of gaseous CsCl. The molecular weights were determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. The pressure sensing element was a fused silica manometer containing Au(ℓ). Based on the reported results, we derive the equilibrium constants for the reaction $Cs_2Cl_2(g) = 2CsCl(g)$ in the temperature range 1224 - 1418 K. The enthalpy change of this reaction is evaluated by the 2nd and 3rd law method as 39.3±1.1 and 42.9±0.6 kcal mol^{-1}, respectively. The drift in the 3rd law value is equivalent to an entropy error of 2.7±0.8 cal $K^{-1}\ mol^{-1}$. Using the 3rd law $\Delta_r H°$ and $\Delta_f H°(CsCl, g, 298.15\ K) = -57.4$ kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K) = -157.7 \pm 2.5$ kcal mol^{-1} (-659.817 ± 10.5 kJ mol^{-1}) for $Cs_2Cl_2(g)$, which is adopted.

Schrier (2) determined the vapor pressures of molten cesium chloride at temperatures between 1165 and 1387 K by the boiling point or manometric method. The vapor analysis was performed using the transpiration method. An inert gas, N_2, was passed over the CsCl sample at a given temperature. The salt vapor entrained by the carrier gas was collected, weighed and analyzed. The data obtained were combined with the boiling point measurements to yield the average molecular weight of the vapor. Association into dimer was postulated. The mole fraction in the vapor and the partial pressure of CsCl(g) and $Cs_2Cl_2(g)$ were calculated. The equilibrium constants, 1209 - 1350 K, for dissociation of the Cs_2Cl_2 dimer were derived. Using the reported equilibrium constants, we evaluate the enthalpy change $\Delta_r H°(298.15\ K)$ of the reaction $Cs_2Cl_2(g) = 2CsCl(g)$ to be 34.1±2.9 and 43.2±0.9 kcal mol^{-1} by the 2nd and 3rd law methods. Based on the 3rd law $\Delta_r H°(298.15\ K)$ value and $\Delta_f H°(CsCl, g, 298.15\ K) = -57.4$ kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K) = -158.0$ kcal mol^{-1} for $Cs_2Cl_2(g)$, which is in agreement with the adopted value.

Miller and Kusch (3) made an analysis of the velocity distribution of the CsCl molecules which escape through an ideal aperture from an isothermal enclosure. They found that there was no definite evidence that any species other than diatomic molecules were present in the beams in measurable amounts, in other words, the dimerization must be small, e.g. <1.5 per cent. However, according to our calculation the concentration of dimer is 15 - 34 per cent in the temperature range 600 - 900 K, and 33 -20 per cent at the temperatures 1000 - 1600 K.

Heat Capacity and Entropy

The molecular structure is assumed to be planar, having D_{2h} symmetry. Based on the bond distances of Cs-Cs and Cl-Cl estimated by Berkowitz (4), the Cs-Cl bond distance and Cl-Cs-Cl bond angle are calculated. The vibrational frequencies were calculated by Berkowitz (5), on the basis of the potential function for an ionic model. The principal moments of inertia are: $I_A = 62.8570 \times 10^{-39}$, $I_B = 210.7205 \times 10^{-39}$, and $I_C = 273.5775 \times 10^{-39}$ g cm^2.

PREVIOUS: June 1968 (1 atm) CURRENT: June 1968 (1 bar)

COPPER CHLORIDE ($CuCl_2$) CRYSTAL M_r = 134.4520

$S°(298.15\ K) = 108.085\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -206.65 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -205.85 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

Shchukarev and Oranskaya have reported equilibrium constants for the dissociation $CuCl_2(cr) + CuCl(cr/\ell) + 0.5\ Cl_2(g)$, which are in general agreement with earlier reports by Ephraim (2) and Tarasenkov et al. (3). These data were subjected to third law analysis which revealed a significant trend of 13±0.5 cal $K^{-1}\ mol^{-1}$, indicating that equilibrium conditions were not reached. However an average value of $\Delta_r H°(298.15\ K) = 16.5 \pm 1.9$ kcal mol^{-1} yields a heat of formation of $CuCl_2(cr) = -49.5 \pm 2.5$ kcal mol^{-1} which is in good agreement with the adopted value taken from (4).

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 11-300 K by Stout and Chisholm (5). The integration of this data from $S°(10\ K) = 0.111$ cal $K^{-1}\ mol^{-1}$ gave $S°(298.15\ K) = 25.833$ cal $K^{-1}\ mol^{-1}$. The heat capacity above 298.15 K was obtained by smooth extrapolation of the above data, since the heat capacities of Krestovnikov and Karetnikov (6) were not compatible with the low temperature data.

Decomposition Data

The temperature of decomposition, T_{dcm} = 766 K, was estimated from the table for $CuCl_2(cr)$, $CuCl(\ell)$ and $Cl_2(g)$ so that the pressure of Cl_2 is 1 bar.

Point Group= C_s

Bond Distances: P-Cl = 1.99 ± 0.04 Å P-F = 1.50 ± 0.03 Å P-O = 1.54 ± 0.03 Å

Bond Angle: Cl-P-Cl = F-P-Cl = 103° O-P-Cl = O-P-F = 115.35°

Product of the Moments of Inertia: $I_A I_B I_C = 4.70925 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

The $\Delta_f H°(298.15\ K)$ of $POFCL_2$ was estimated to be -183 kcal mol^{-1} from the $\Delta_f H°(298.15\ K)$ of $POCl_3$ by assuming bond energies of 120 kcal mol^{-1} for D(P-F) and 80 kcal mol^{-1} for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from Neale and Williams (1) and Neale et al. (2).

Essentially the same $\Delta_f H°(298.15\ K)$ may be obtained by assuming a $\Delta_r H° = 0$ for the following reaction:

$$POCl_3(g) + POF_3(g) \rightarrow POCl_2F(g) + POF_2Cl(g)$$

Heat Capacity and Entropy

The molecular constants were determined by Brockway and Beach (3) and by Williams et al. (4). Brockway and Beach used electron diffraction. Williams et al. (4) measured microwave spectra. Brockway and Beach (3) assumed that the F-P-F and F-P-Cl angles were equal in POF_2Cl and $POFCl_2$. An analysis of their data by Williams et al. (4) indicates that the angles in POF_2Cl, $POFCl_2$, and $POCl_3$, and POF_3 should be 103° rather than the reported 106° ± 3°. The principal moments of inertia are: $I_A = 26.9230 \times 10^{-39}$, $I_B = 37.9561 \times 10^{-39}$, and $I_C = 46.0837 \times 10^{-39}$.

The Raman spectra and vibrational frequencies for $POFCl_2$ were reported by Delwaulle and Francois (5). These frequency assignments are summarized by Delwaulle and Francois (6).

PREVIOUS: March 1963 (1 atm) CURRENT: March 1963 (1 bar)

$S°(298.15\ K) = 117.947 \pm 3.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 950\ K$

$\Delta_f H°(0\ K) = -344.419 \pm 0.42\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -341.833 \pm 0.42\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.012 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

Koehler and Coughlin (1) determined $\Delta_r H°(298.15\ K) = -4.06 \pm 0.05$ kcal mol^{-1} for Fe(α) + 2 HCl(12.731 H_2O) = $FeCl_2$(cr) + H_2(g) by solution calorimetry. This leads to $\Delta_f H°(FeCl_2, cr, 298.15\ K) = -81.7 \pm 0.1$ kcal mol^{-1} which is adopted in the tabulation. The value $\Delta_f H°(298.15\ K)$ [HCl(12.731 H_2O)] = -38.812 kcal mol^{-1} (2) is used in the calculation.

Li and Gregory (3) also determined calorimetrically $\Delta_r H°(298.15\ K) = -19.5 \pm 0.2$ kcal mol^{-1} for $FeCl_2$(cr) + Fe^{++}(aq) + 2 Cl^-(aq) in aqueous solution at concentrations near 10^{-3} molal. Using $\Delta_f H°(Fe^{++}, aq, \infty\ 298.15\ K) = -21.3$ kcal mol^{-1} (4) and $\Delta_f H°(Cl^-, aq, \infty\ 298.15\ K) = -39.952$ kcal mol^{-1} (2), we have obtained $\Delta_f H°(FeCl_2, cr, 298.15\ K) = -81.7$ kcal mol^{-1} which is in excellent agreement with the adopted value.

Kangro and Petersen (5) determined the equilibrium constants for the reaction $FeCl_2$(cr) + H_2(g) = Fe(cr) + 2 HCl(g) in the temperature range from 484-662°C. By use of 2nd and 3rd law analyses, the enthalpy of reaction is evaluated as 37.81 and 38.24 kcal mol^{-1}, respectively. Using the 3rd law $\Delta_r H°(298.15\ K)$, we obtain $\Delta_f H°(FeCl_2, cr, 298.15\ K) = -82.36 \pm 0.5$ kcal mol^{-1} which is in reasonable agreement with the value adopted.

Heat Capacity and Entropy

Kelley and Moore (6) measured the low temperature heat capacities in the temperature range from 53.2 - 295.0 K and made an extrapolation to 0 K which yielded an entropy of 5.19±0.8 cal K^{-1} mol^{-1} at 50.12 K. This value also includes the uncoupling energy of Fe^{++} ($R\ln 5$ = 3.2 cal K^{-1} mol^{-1}). We have adopted the measured heat capacities, but made a minor adjustment of the entropy at 53.2 K to 4.93 cal K^{-1} mol^{-1} which is still within the limit of uncertainty, but yields the entropy at 298.15 K as 28.19 cal K^{-1} mol^{-1}. The latter was found by E. F. Westrum (7).

Moore (8) measured high temperature enthalpy data from 670.5 to 941 K by drop calorimetry. The low temperature heat capacities and high temperature enthalpy data were smoothly joined at 298.15 K. The $C_p°$ values above 941 K were obtained by graphical extrapolation. Oetting and Gregory (9) measured high temperature heat capacities in the temperature range from 60 to 500 C in a constant heating adiabatic calorimeter. Their $C_p°$ values are in good agreement with those found by Moore (8).

Fusion Data

T(fus) and $\Delta_{fus} H°$ were taken from Moore (8).

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ for the monomer and dimer are calculated from the adopted enthalpies of formation of the crystal and the respective gaseous species.

PREVIOUS: June 1965 CURRENT: December 1970

$S°(298.15\ K)$ = [139.876] J K^{-1} mol^{-1}

T_{fus} = 950 K

$\Delta_f H°(298.15\ K)$ = [-311.336] kJ mol^{-1}

$\Delta_{fus} H°$ = 43.012 ± 0.21 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(FeCl_2, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(950\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Moore (1) derived the constant heat capacity from enthalpy data measured in the temperature range from 950 to 1100 K in a drop calorimeter. The constant $C_p°$ is assumed for all the other temperatures. The entropy is calculated a manner similar to that used for the enthalpy of formation.

Fusion Data

T_{fus} and $\Delta_{fus} H°$ were taken from Moore (1).

Vaporization Data

The boiling point, T_{vap} = 1297 K, is the calculated temperature at which the sum of the partial pressures of $FeCl_2(g)$ and $Fe_2Cl_4(g)$ over $FeCl_2(\ell)$ reaches one atmosphere. At T_{vap}, the mole fraction of the dimer is 0.1635. The enthalpy of vaporization is calculated to be the difference between the enthalpies of formation at 1297 K for one mole of $FeCl_2(\ell)$ vaporizing to the equilibrium mixture of 0.719 moles of $FeCl_2(g)$ and 0.1403 moles of $Fe_2Cl_4(g)$.

Enthalpy of Formation

Using the Gibbs energy functions of monomeric and dimeric $FeCl_2(g)$ with the adopted enthalpy of dimerization at 298.15 K, $\Delta_{dim}H° = -35.7\ kcal\ mol^{-1}$ (1), we have derived partial pressure of monomeric $FeCl_2$ from the reported pressure data (2-7). Schafer (4) determined Kp for the equilibrium reaction C assuming the dimer concentration was insignificant at the equilibrium conditions.

Reaction: A) $FeCl_2(\ell) + FeCl_2(g)$; B) $FeCl_2(cr) + FeCl_2(g)$; C) $Fe(cr) + 2\ HCl(g) + H_2(g)$.

[a] 1 point rejected due to failure of a statistical test.

The adopted value, $\Delta_f H°(FeCl_2, g, 298.15\ K) = -33.7\ kcal\ mol^{-1}$, is in very good agreement with those derived from the reactions A and C. The adopted value is also between the more discrepant results for reaction B derived from mass spectrometry and from effusion studies. This implies that the total pressures calculated from the monomer and dimer tables fit the observed vapor pressures over liquid much better than those over solid. For the liquid, the ratio of the calculated to the observed vapor pressure is about 1.0 ± 0.1 and for the solid, the ratio is about 1.3 ± 0.2

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicated that other transition metal dichlorides are linear (8). The bond distance is estimated by comparison with that of $Fe_2Cl_6(g)$ reported by Zasorin (9). The ground state ($^5\Delta$), low lying electronic levels and the quantum weights were obtained from the work of Dekock and Gruen (10).

The asymmetric stretching frequency was observed in the infrared spectra of the vapor at 492 cm^{-1} by Leroi (11) and at 494 cm^{-1} in Ar matrices by Thompson (12) and Frey (13). Normal coordinate analysis yields the stretching force constant k_1 = 2.23 md/Å which leads to the stretching vibrational frequency, ν_1 = 327 cm^{-1}, by a valence force field model. The bending frequency, ν_2 = 88 cm^{-1} was observed in the matrix infrared spectra (12).

The drift indicated that the entropy of $FeCl_2(g)$ is made more consistent by introducing two low lying electronic levels and a relatively low bending frequency. The enthalpies derived by 2nd and 3rd law analyses are in good agreement.

Ground State Quantum Weight = [1] $\sigma = 2$

Point Group: C_{2v}

Bond Distances: Si-H = 1.480 Å Si-Cl = 2.033 Å

Bond Angles: H-Si-H = 111.3° Cl-Si-Cl = 109.72°

Product of the Moments of Inertia: $I_A I_B I_C = 7.53113 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated from values for $SiCl_4$, $SiHCl_3$, and SiH_4(1). Data for $SiHCl_3$ (1) suggest that $\Delta_f H°$ shows minor deviations from linearity in the chlorosilanes. We assume that $\Delta_f H°$ has a cubic variation with a constant third difference of -1.5 kcal mol^{-1}. $\Delta_f H°$ values of the chloromethanes yield an almost constant third difference of about -2.5 kcal mol^{-1} (2, 3, 1). This approximation corresonds to Allen's bond additivity scheme involving near-neighbor interactions taken two and three at a time (2). Our adopted $\Delta_f H°$ is 1.5 kcal mol^{-1} more negative than that estimated by linear interpolation between $SiCl_4$ and SiH_4.

Heat Capacity and Entropy

The molecular structure is based on microwave data of Davis and Gerry (4) for three isotopic forms of dichlorosilane. Structural parameters are essentially substitutional (r_s) values. They are in reasonable agreement with an early electron diffraction study (5). The principal moments of inertia are $I_A = 5.9928 \times 10^{-39}$, $I_B = 33.0411 \times 10^{-39}$ and $I_C = 38.0343 \times 10^{-39}$ g cm^2.

Vibrational frequencies are those selected by Shimanouchi (6) from a gas-phase infrared study of SiH_2Cl_2, $SiDHCl_2$ and SiD_2Cl_2 done by Christensen and Nielsen (7). Assignments are based on band contours and isotopic rules and are supported by theoretical calculations (7, 4). Two frequencies, ν_4 = 188 and infrared inactive ν_5 = 710 cm^{-1}, are from liquid-phase Raman spectra (8) which also support the vibrational assignment. Christensen and Nielsen (7) found a weak infrared band at ~190 cm^{-1} but could not estimate a definite band contour.

We neglect excited states and assume the electronic ground state to be a singlet. A recent vacuum ultraviolet study of Si_2HCl_2 (9) is not available to us. We assume that there is little shift in electronic levels between SiH_2Cl_2 and SiH_3Cl (1), since there is little shift in absorption spectra between CH_2Cl_2 and CH_3Cl (10). This implies that contributions from the excited states in SiH_2Cl_2 should be unimportant, just as we believe them to be in SiH_3Cl (1).

MERCURIC CHLORIDE ($HgCl_2$) CRYSTAL M_r = 271.496

$S°(298.15\ K) = [144.494 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 550\ K$

$\Delta_f H°(298.15\ K) = -230.12 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H = 19.414 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

Taken from (1).

Heat Capacity and Entropy

$C_p°$ was determined from the enthalpy data of Topol and Ransom (2) and Ewald (3). Above 550 the curve was smoothly extrapolated. The entropy was estimated by adjusting the value to give the best fit of the melting, sublimation, and vaporization data.

Melting

T_{fus} was taken from (1). $\Delta_{fus}H$ was given by Topol and Ransom (2).

MERCURIC CHLORIDE ($HgCl_2$) LIQUID M_r = 271.496

$S°(298.15\ K)$ = [164.471] J K^{-1} mol^{-1} $\Delta_f H°(298.15\ K)$ = [-213.222] kJ mol^{-1}

T_{fus} = 550 K $\Delta_{fus}H°$ = 19.414 ± .21 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(HgCl_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(550 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity was estimated to conform with the bromide and iodide, the value given by Topol and Ransom (1) was discounted. A glass type transition was assumed to be 367 K below which the heat capacity was equal to that of the crystal. The entropy was obtained from S°(cr), the entropy of fusion and the estimated heat capacity.

Fusion and Vaporization

T_{fus} and T_{vap} were taken from (2). $\Delta_{fus}H°$ was given by Topol and Ransom (1) and $\Delta_{vap}H$ was obtained from Prideaux (3) and Johnson (4); T_{vap} = 577 K and $\Delta_{vap}H°$ = 58.9 kJ mol^{-1}.

Mercury Chloride ($HgCl_2$) Cl_2Hg_1(cr,l)

MERCURIC CHLORIDE ($HgCl_2$) IDEAL GAS M_r = 271.496

$S°(298.15\ K) = 294.793\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -142.31 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -146.29 \pm 6.3\ kJ\ mol^{-1}$

Vibrational Levels and Multiplicities

ν, cm^{-1}
360 (1)
70 (2)
413 (1)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Hg-Cl = 2.31 A

Bond Angle: O-Hg-Cl = 180°

Rotational Constant: $B_o = 0.044554\ cm^{-1}$

Enthalpy of Formation

The heat of formation of the crystal as given in (1) was combined with the 3rd law enthalpy of sublimation at 298.15 K from the data of Niwa and Zhibata (2), Ruf and Treadwell (3) and Johnson (4).

Heat Capacity and Entropy

The vibrational constants were given by Klemperer and Lindeman (5). The bond length is a weighted average of the values given by Braune and Knoke (6), Gregg et al. (7), Maxwell and Mosely (8), and Akishin et al. (9).

MERCUROUS CHLORIDE (Hg_2Cl_2) CRYSTAL M_r = 472.086

$\Delta_f H°(0\ K) = -260.537 \pm 0.21\ kJ\ mol^{-1}$

$S°(298.15\ K) = 192.535\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = -264.927 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation is based on the average Gibbs energy of formation, -50.315 kcal mol^{-1}, as measured by Gerke (1) and Hills and Ives (2), and the entropy of formation.

Heat Capacity and Entropy

The data of Pollitzer (3) from 22-199 K was treated by Kelley (4). The heat capacities listed by Kelley were raised by 0.06 to match the entropy data of Gerke (1). Data above room temperature were obtained by smooth extrapolation. A mean value of the entropy of formation of -46.614 cal K^{-1} mol^{-1} was adopted from the cell measurements of Gerke (1).

Sublimation

The vapor pressure over mercurous chloride reaches 1 atmosphere at 655 K according to Smith and Menzies (5). At this point the vapor is dissociated into $Hg(g)$ and $HgCl_2(g)$.

Enthalpy of Formation

The enthalpy of formation is calculated from that of KCl(g) using $\Delta_r H°(298.15\ K) = 45.0$ kcal mol^{-1} for $K_2Cl_2(g) \rightarrow 2\ KCl(g)$ as selected from data analyses summarized below. The three experimental techniques include PVT measurements (1), combination of total vapor pressure and transpiration data (2,3,4), and mass spectrometric studies of the variation of ion intensities with temperature (5). The results are reasonably consistent, considering the uncertainties inherent in the problem.

The resulting tables were tested by comparison with other data. Calculated total vapor pressures are in satisfactory agreement with the observed values over the range 820-1500 K; however, near the boiling point they are lower by 6-18 percent [see KCl(g)]. Knudsen effusion data and transpiration data over KCl(cr) have been reviewed by Pugh and Barrow (6). These data suggest negligible dimer formation when combined with the total vapor pressures of Pugh and Barrow (6) but significant dimer formation when combined with the lower (20-30 percent) total pressures of Dietz (7). Calculated dimer formation (22 mole percent at 900 K) agrees with the latter combination but calculated total pressures agree with those of Pugh and Barrow (6). Velocity distribution studies of Miller and Kusch (8) suggest about 10 mole percent of dimer at 900 K. Thus, while minor inconsistencies do exist, it is not apparent that they exceed the combined experimental errors.

Heat Capacity and Entropy

The structure and vibrational frequencies are those calculated from an ionic model by Berkowitz (9). The sixth fundamental was arbitrarily lowered from 206 to 100 cm^{-1} since the resulting entropy increase (1.4 cal K^{-1} mol^{-1} at 1300 K.) improved the overall agreement with the equilibrium data. Based on electron diffraction studies of the monomer-dimer vapor, Akishin and Rambidi (10) have derived the bond distance and angle to be 2.81 Å and 98°. Interpretation of the diffraction data, however, is complicated by the presence of only about 30 mole percent of dimer at the temperature of measurement. Adoption of this dimer structure would reduce the entropy by 0.23 cal K^{-1} mol^{-1}. Principal moments of inertia for the Berkowitz structure are $I_A = 45.3554 \times 10^{-39}$, $I_B = 60.0935 \times 10^{-39}$, and $I_C = 105.4488 \times 10^{-39}$ g cm^2.

Ground State Quantum Weight: 1 σ = 4
Point Group: D_{2h}
Bond Distance: Li-Cl = 2.23 Å Li-Li = 2.62 Å
Bond Angle: Cl-Li-Cl = 108 ± 4°
Product of the Moments of Inertia: $I_A I_B I_C$ = 6.41793 x 10^{-114} g^3 cm^6

Enthalpy of Formation

An enthalpy of sublimation at 298.15 K of 52.1 kcal mol^{-1} was chosen to fit the vapor pressure data and relative concentrations of monomer, dimer and trimer as described in the table for LiCl(g). This value is in reasonable agreement with the value of 53.5 kcal mol^{-1} from a 3rd law analysis of the vapor pressure data of Nesmeyanov and Sazonov (1) and the relative concentrations of monomer, dimer, and trimer from the work of Miller and Kusch (2). Also a value of 54.1 kcal mol^{-1} was found by Milne and Klein (3) from mass spectrometer studies.

Heat Capacity and Entropy

Klemperer and Norris (4) observed two bands in the infrared spectrum and made tentative assignments. The remaining four frequencies were calculated by Berkowitz (5) from a reasonable model. The bond lengths and angles were determined from the electron diffraction experiments of Bauer et al. (6). The principal moments of inertia are: I_A = 3.9605 x 10^{-39}, I_B = 38.3234 x 10^{-39}, and I_C = 42.2839 x 10^{-39} g cm^2.

PREVIOUS. June 1962 (1 atm) CURRENT: June 1962 (1 bar)

MAGNESIUM CHLORIDE ($MgCl_2$) CRYSTAL M_r = 95.211

$S°(298.15\ K) = 89.629\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 987\ K$

$\Delta_f H°(0\ K) = -641.196 \pm 0.46\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -641.616 \pm 0.46\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.095 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -153.35 \pm 0.11\ kcal\ mol^{-1}$ is from enthalpy of solution measurements reported by Shomate and Huffman (1). Shomate and Huffman's enthalpy of solution of Mg in 1 M HCL ($\Delta_f H = -111.322 \pm 0.041\ kcal\ mol^{-1}$) has been substantiated for calibration purposes by Gunn and Cunningham (2) ($\Delta_f H = -111.3\ kcal\ mol^{-1}$) and by Westrum and Eyring (3) ($\Delta_f H = -111.27\ kcal\ mol^{-1}$). Auxiliary enthalpy of dilution and enthalpy of formation data for HCl were taken from Parker (4) and from Wagman et al. (5).

Heat Capacity and Entropy

High temperature heat content data by Moore (6) were joined by Shomate correlation with low temperature heat capacity data reported by Kelley and Moore. $C_p°(cr)$ above T_{fus} is a linear extrapolation from 700 K. S°(298.15 K) is derived from the low temperature data and is based on $S°(53.6\ K) = 2.006\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

$\Delta_{fus} H° = 10.30 \pm 0.05\ kcal\ mol^{-1}$ is taken from enthalpy measurements of Moore (6). T_{fus} = 987 K is from (8).

Sublimation Data

The value of $\Delta_{sub} H°(298.15\ K)$ was derived by 2nd and 3rd law analyses of vapor pressure data. See the ideal gas table for details.

PREVIOUS: December 1960 CURRENT: December 1965

$S°(298.15\ K) = [129.480] J\ K^{-1}\ mol^{-1}$

T_{fus} = 987 K

$\Delta_f H°(298.15\ K) = [-601.577]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.095 \pm 0.21\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(MgCl_2, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MgCl_2, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(987\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A constant $C_p°(\ell) = 22.0\ cal\ K^{-1}\ mol^{-1}$ over the temperature range 1006-1428 K is from the high temperature enthalpy data of Moore (1). This constant value was assumed to hold from an assumed glass transition of 660 K to 3000 K. $C_p°(\ell)$ below 660 K is taken to be that of the crystal. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which the Gibbs energy change of the reaction $MgCl_2(\ell) = MgCl_2(g)$ is zero. The difference between $\Delta_f H°$ for $MgCl_2(\ell)$ and $MgCl_2(g)$ at T_{vap} is $\Delta_{vap} H°$.

Magnesium Chloride ($MgCl_2$) Cl_2Mg_1(cr,l)

$S°(298.15\ K) = 277.027 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -392.57 \pm 2.1\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -392.46 \pm 2.1\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν_i, cm^{-1}
590 (1)
88 (2)
[273](1)

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: $D_{\infty h}$
Bond Distance: Mg-Cl = 2.18 Å
Bond Angle: Cl-Mg-Cl = 180°
Rotational Constant: $B_0 = 0.050027\ cm^{-1}$

Enthalpy of Formation

Analysis of vapor pressure data on $MgCl_2$ is clouded by conflicting evidence for the amount of dimer in the vapor. Berkowitz and Marquart (1) by mass spectrometer studies found about 2% dimer at 920 K and derived $\Delta_{dim}H = -39.2$ kcal mol^{-1} and $\Delta_{dim}S = -29.9$ cal K^{-1} mol^{-1}. Schrier and Clark (2) from gas transpiration data calculated about 30% dimer in the saturated vapor at 1300 K with $\Delta_{dim}H = -32.0$ kcal mol^{-1} and $\Delta_{dim}S = -18.8$ cal K^{-1} mol^{-1}. Thermodynamic functions for the gaseous monomer adopted here are clearly not compatible with large amounts of dimer and it is assumed for the present that the mass spectrometer results are correct.

Several vapor pressure studies have been published and third law analyses are given below. Berkowitz and Marquart (1) gave a single point while the remaining publications gave only equations but not individual points. Total pressures calculated from the equations were corrected for dimer.

Source	Method	T/K	$\Delta_{sub}H°(298.15\ K)$ kcal mol^{-1} Third Law
Berkowitz and Marquart (1)	Mass spectrometer	920	58.10
Schrier and Clark (2)	Boiling Point	1208-1413	59.55-59.68
Hildenbrand et al. (3)	Torsion-effusion	802-985	59.55-59.19
Hildenbrand et al. (4)	Torsion-effusion	800-970	59.53-59.38
Fischer et al. (5)	"Bell" method (total vapor pressures)	1136-1435	59.30-59.56

The selected value for $\Delta_{sub}H°(298.15\ K)$ is 59.55 kcal mol^{-1} which is combined with $\Delta_f H°(298.15\ K)$ of the crystal to give $\Delta_f H°(g, 298.15\ K) = -93.80$ kcal mol^{-1}.

Heat Capacity and Entropy

White, Mann, and co-workers (6) by matrix infrared spectroscopy determined the molecule to be linear with the asymmetric stretching frequency at 590 cm^{-1} and the doubly degenerate bending frequency at 88 cm^{-1}. The symmetric stretching frequency was estimated as 273 cm^{-1}. The asymmetric stretching was observed by Buchler and Klemperer (7) at 597 cm^{-1} and by Randall et al. (8) at 598 cm^{-1}, both by infrared spectroscopy of the vapor at high temperature. Electric deflection experiments by Klemperer and co-workers as summarized by Hayes (9) and the electron diffraction data of Akishin and Spiridonov (10) agree with the linear structure within their error limits of about 20. The Mg-Cl bond length was determined as 2.18 Å by Akishin and Spiridonov (10).

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

MOLYBDENUM CHLORIDE OXIDE (MoO_2Cl_2) IDEAL GAS M_r = 198.8448

$S°(298.15\ K)$ =337.787± 5.44 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = -628.99 ± 14.6 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = -633.04 ± 14.6 kJ mol^{-1}

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}	ν, cm^{-1}
972 (1)	134 (1)	156 (1)
453 (1)	233 (1)	437 (1)
347 (1)	996 (1)	287 (1)

Ground State Quantum Weight: 1 σ = 2

Point Group: C_{2v}

Bond Distances: Mo-O = 1.75 ± 0.10 Å Mo-Cl = 2.28 ± 0.03 Å

Bond Angles: O-Mo-O = 109.5° Cl-Mo-Cl = 113°

O-Mo-O plane perpendicular to Cl-Mo-Cl plane

Product of Moments of Inertia: $I_A I_B I_C$ = 1.09994 x 10^{-112} g^3 cm^6

Enthalpy of Formation

Graham and Hepler (1) determined calorimetrically $\Delta_r H°$ = -65.3 ± 0.5 kcal mol^{-1} for the reaction:

$$MoO_2Cl_2(cr) + 4\ NaOH(\infty H_2O) + Na_2MoO_4(\infty H_2O) + 2\ NaCl(\infty H_2O) + 2\ H_2O(\ell).$$

Combining this result with the following enthalpy of formation data; $\Delta_f H°(Na_2MoO_4, \infty H_2O)$ = -353±0.4 kcal mol^{-1} (2); $\Delta_f H°(NaCl, \infty H_2O)$ = -97.33±0.09 kcal mol^{-1} (3, 4); $\Delta_f H°(NaOH, \infty H_2O)$ = -112.46±0.1 kcal mol^{-1} (3, 4); $\Delta_f H°(H_2O, \ell)$ = -68.315 kcal mol^{-1} (5); we derive $\Delta_f H°(MoO_2Cl_2, cr)$ = -169.6±1.0 kcal mol^{-1}.

Shchukarev et al. (6) measured the heats of solution of MoO_3(cr), MoO_2Cl_2(cr) and NaCl(cr) in NaOH(aq) and derived $\Delta_r H°$ = -45.56±0.5 kcal mol^{-1} for the reaction $MoO_2Cl_2(cr) + 2\ NaOH \cdot 77\ H_2O + MoO_3(cr) + 2\ NaCl(cr) + H_2O(\ell)$. Using JANAF auxiliary data (3, 4), we obtain $\Delta_f H°(MoO_2Cl_2, cr, 298.15\ K)$ = -172.86±1.0 kcal mol^{-1}.

The two investigations differ only in the heat of solution of MoO_2Cl_2(cr), both samples were better than 99.9% pure, and multiple determinations on two different samples were employed in each case. We adopt an average of the two values, -171.2±1.7 kcal mol^{-1} for $\Delta_f H°(MoO_2Cl_2, cr, 298.15\ K)$. Shchukarev et al. (8) reported an equation for the vapor pressure over the solid from which we have calcualted a 2nd law $\Delta_{sub}H°(298.15\ K)$ = 19.9 kcal mol^{-1} with an estimated uncertainty of ±2 kcal mol^{-1}, a ΔCp correction of -4.1 cal K^{-1} mol^{-1} was used (3). Thus, our adopted value is $\Delta_f H°(MoO_2Cl_2, g, 298.15\ K)$ = -151.3±3.5 kcal mol^{-1}.

Shchukarev et al. (7) reported equilibrium constants for the reaction $MoO_2Cl_2(g) + 0.5\ O_2(g) = MoO_3(cr) + Cl_2(g)$. Shchukarev et al. (8) and Hultgren and Brewer (9) reported equilibrium data for the reaction $MoO_3(cr) + 2\ HCl(g) = MoO_2Cl_2(g) + H_2O(g)$. 2nd and 3rd law analysis of these equilibrium data give the following results:

Source	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$-\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(7)	7	-15.6	-30.11±2.0	-15.0	148.0 ± 3.0
(8)	Eqn	12.1	13.8 ±1.0	2.95	150.6 ± 1.2
(9) Set I	5	27.2	15.2 ±1.7	-21.37	149.2 ± 2.0
Set II	5	26.5	15.4 ±3.2	-21.75	149.4 ± 3.5

These equilbrium data are in agreement with the adopted enthalpy of formation but are suspect because of the significant drifts and because the range of validity of the equation (8) is estimated.

Heat Capacity and Entropy

The molecular structural data are from the compilation of Sutton (10). Infrared data (11, 12, 13) for vapor phase MoO_2Cl_2 have indicated that the molecule possesses a distorted tetrahedral structure by reason of the similarity of its spectra to that of CrO_2Cl_2. Principal moments of inertia are I_A = 32.2143 x 10^{-39}, I_B = 53.4145 x 10^{-39}, and I_C = 63.9238 x 10^{-39} g cm^2.

The vibrational frequencies 972, 996, 453, and 437 have been observed in the infrared vapor phase spectra of MoO_2Cl_2 by Barraclough and Stals (11). These frequencies were assigned to the symmetric and asymmetric Mo-O and Mo-Cl stretches, respectively. Similar infrared data for these four frequencies have been reported by Iorns and Stafford (12) and Ward and Stafford (13). The rest of the frequencies are from the infrared and Raman studies of crystalline MoO_2Cl_2 by Adams and Churchill (14). Assignments are made by comparison with data reported for $CrO_2Cl_2(\ell)$ by Miller et al. (15).

Enthalpy of Formation

An analysis is given below of the more extensive measurements relating to the dimer dissociation, $(NaCl)_2(g) \rightarrow 2\ NaCl(g)$. The mass spectrometric studies suggest that higher polymeric species may be neglected. Velocity distribution analyses are consistent with this procedure. When reduced to 298.15 K, the observed heats of dissociation of the dimer show a range of more than 7 kcal mol^{-1}, reflecting the considerable uncertainty involved in such measurements. A value of $\Delta_r H°(298.15\ K) = 48.6$ kcal mol^{-1} was selected for the dissociation; combining this with $\Delta_{sub} H°(298.15\ K) = 54.9$ kcal mol^{-1} for sublimation to the monomer leads to $\Delta_{sub} H°(298.15\ K) = 61.2$ kcal mol^{-1} for sublimation to the dimer.

Heat Capacity and Entropy

The structure and vibrational frequencies are those calculated from an ionic model by Berkowitz (8). Electron diffraction studies by Akishin and Rambidi (9) gave a similar bond angle (108°) and a slightly shorter bond distance (2.50 Å); however, interpretation of the diffraction pattern was complicated by uncertainty in the monomer-dimer ratio for the vapor. Principal moments of inertia for the Berkowitz structure are $I_A = 17.9886 \times 10^{-39}$, $I_B = 53.3306 \times 10^{-39}$ and $I_C = 71.3192 \times 10^{-39}$ g cm^2.

NICKEL CHLORIDE ($NiCl_2$) CRYSTAL M_r = 129.596

$S°(298.15\ K) = 98.157 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1304 \pm 4\ K,\ p = 2.5\ atm$

$\Delta_f H°(0\ K) = -305.389 \pm 0.21\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -304.930 \pm 0.21\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 77.170 \pm 0.84\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ of -72.88 ± 0.5 kcal mol^{-1} is based on our 3rd law analysis of equilibrium data for the reaction $NiCl_2(cr) + H_2(g) \rightarrow Ni(cr) + 2HCl(g)$ of Busey and Giauque (1). This value is selected from the studies shown below mainly because of the attention to purity of the sample, assurance of equilibrium, and correction for diffusion of hydrogen through pyrex by these authors. The results of Busey and Giauque (1) show excellent agreement between 2nd and 3rd law values with a consequent low drift. Our analysis of the other studies is given below and the large drifts for some of the studies indicate a lack of equilibrium which is attained very slowly in this system; this is certainly the case for Shchukarev et al. (2) and possibly also for (3, 4, 5). The emf results of Egan (6) and Gee and Shelton (7) are about 0.5 kcal mol^{-1} more negative than the adopted value and we increase the uncertainty in the event that these results prove to be more accurate.

B) $Ni(cr) + Cl_2(g) \rightarrow NiCl_2(cr)$

C) $Co(cr) + NiCl_2(g) \rightarrow CoCl_2(cr) + Ni(cr)$

D) $Fe(cr) + NiCl_2(g) \rightarrow FeCl_2(cr) + Ni(cr)$

Heat Capacity and Entropy

Heat capacity data below 300 K are based on the measurements of Kostryokova (8) (2-30 K) and Busey and Giauque (9) (14.14-336.36 K). The two sets of data are joined smoothly via a least squares procedure; Kostryokova's values (8) are higher than those of Busey and Giauque (9) by 5.3% at 15 K and 0.3% at 30 K. The results of Busey and Giauque (9) indicate a sharp lambda peak at 52.35 K which is apparently associated with the cooperative ordering of the magnetic moments of the nickel ions. $C_p°$ near the maximum is 6.74 cal K^{-1} mol^{-1} and the enthalpy associated with this transition is of the order of a few calories. The only other measurements in this temperature region are by Trapeznikowa et al. (10) (13-129 K) who report three peaks in $C_p°$ at 49.55 K, 57-58 K, and 60-61 K. We put no weight on these results since the authors apparently suffered from an impure sample among other experimental problems (9); their results range from 4 to 13% higher than those of Busey and Giauque over the temperature range 40-130 K. Earlier results by Kostryokova (11) below 16 K are in good agreement with the adopted $C_p°$ values. $S°(298.15\ K)$ is obtained from integration of the adopted $C_p°$'s and is based on $C_p°(2\ K) = 0.0055$.

$C_p°$ data above 300 K are based on the high temperature enthalpy data of Coughlin (12) (376-1282 K). These data are corrected to IPTS 68 (13) and then joined smoothly with the low temperature $C_p°$ data of Busey and Giauque (9) to yield the adopted $C_p°$ values. Data above 1300 K are extrapolated. The high temperature enthalpy data of Krestovnikov and Karetinkov (14) range from 2 to 11% higher than those of Coughlin and are believed to be of lower accuracy.

Fusion Data

See the liquid table for details.

Sublimation Data

$T_{sub} = \sim 1245$ K is calculated as the temperature at which $\Delta_r G = 0$ for $NiCl_2(cr) \rightarrow NiCl_2(g)$ (15). See the enthalpy of formation section of the $NiCl_2(g)$ table (15) for the derivation of the adopted enthalpy of sublimation.

PREVIOUS: CURRENT: September 1977

$S°(298.15\ K)$ = [151.810] J K^{-1} mol^{-1}

T_{fus} = 1304 ± 4 K, p ≅ 2.5 atm

$\Delta_f H°(298.15)$ = [−233.516] kJ mol^{-1}

$\Delta_{fus} H°$ = 77.170 ± 0.84 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(NiCl_2, l, 298.15\ K)$ is calculated from that of the crystal by addition of $\Delta_{fus} H°$ and the difference in enthalpy, H°(1304 K) − H°(298.15 K), between the crystal and liquid (1).

Heat Capacity and Entropy

The adopted values of $C_p°$ are obtained from our analysis of the high temperature enthalpy data of Coughlin (2) (1305-1337 K) after correction to IPTS 68 (3). The constant $C_p°$ value obtained from these data is assumed to be valid above an assumed glass transition temperature at 880 K. The assumption of a constant $C_p°$ over such a broad range based on data over a very short range leads to a rather large uncertainty in the thermal functions. Below the glass transition at 880 K, $C_p°$ is assumed to be that of the crystal.

S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The temperature and heat of melting are obtained from our analysis of Coughlin's (2) measurements after correction to IPTS 68 (3). He observed pre-melting beginning at 1288 K and continuing to 1305 K where the enthalpy change again becomes regular. We adopt a melting point near the upper end of this range, T_{fus} = 1304±4 K. The adopted enthalpy of melting is 18.444±0.2 kcal mol^{-1} at T_{fus}.

Phase Data

$NiCl_2(\ell)$ will not exist as a stable phase at 1 bar pressure according to calculations from our tables (1). We calculate sublimation at ~1245 K in good agreement with the measured value of 1241±3 K at 730 torr (4). The adopted melting point of 1304±4 K is from Coughlin's work which was conducted at 2-3.5 atm in the presence of inert gas. These pressures are high enough to increase the sublimation point above the melting point and a relatively short liquid range will be observed. Information on the enthalpy of sublimation is in the enthalpy of formation section of the ideal gas table (1).

Enthalpy of Formation

The adopted value of $\Delta_f H°(298.15\ K)$ is calculated from $\Delta_{sub} H°(298.15\ K) = 55.21 \pm 0.3$ kcal mol^{-1} by addition of $\Delta_f H°(NiCl_2, cr, 298.15\ K)$ (1). The adopted value is an average derived from our 3rd law analysis of the sublimation data of Ratkovskii et al. (2), McCreary and Thorn (3), Schaefer et al. (4), and Hildenbrand (5). The data of Maier (6) are rejected because there is an apparent temperature dependent error at the high temperature end of his data.

Schoonmaker et al. (7) observed no dimers in their Knudsen-mass spectroscopic study while Schaefer and Binnewies (8) observed dimerization to the extent of 0.15% at 796 K by a similar technique. We have not corrected for this small dimerization effect. Of more importance may be the observation of significant quantities of $SiCl_4(g)$ and $Si_2Cl_6(g)$ by Schoonmaker et al. (7) indicating reaction between $NiCl_2(g)$ and the quartz liner in their experiment. Schaefer and Binnewies (8) make no mention of Si_xCl_y species even though their Knudsen cell contains a quartz crucible. Therefore we ignore this effect while recognizing the need for further work in the characterization of the vapor over $NiCl_2$.

Heat Capacity and Entropy

The adopted gas phase values of ν_2 = 87 cm^{-1} and ν_3 = 523 cm^{-1} are from the matrix isolation work of Thompson and Carlson (9), we have added 2 cm^{-1} to the observed values to account for the matrix effect. The symmetric stretching frequency, ν_1, has not been observed in the infrared spectrum and this is one of the major indications that the molecule is linear. The adopted value of ν_1 (360 cm^{-1}) is from the observed vibrational spacing of the fluorescence spectrum by Gruen et al. (10) and is in good agreement with the value of 351 cm^{-1} calculated by Milligan et al. (11).

The rotational constant is calculated assuming the molecule is linear with the bond distance estimated to be 2.09 Å in accordance with Brewer et al. (12). Further support for a linear structure comes from the molecular beam work of Buchler et al. (13) which indicates a zero dipole moment for a number of transition metal difluorides including NiF_2.

The ground state of the linear $NiCl_2$ molecule is established as $^3\Pi g$ from numerous studies on the Laporte-forbidden d-d transitions (14 - 16) as well as a study of the Laporte-allowed charge-transfer transitions (17). The very complex electronic spectra for both the gas phase and matrix isolated $NiCl_2$ have been studied by numerous investigators and interpreted using crystal field or ligand field theory. Our adopted values for the excited states are from Lever and Hollebone (14) who used an "orbital angular overlap" model to fit the spin-allowed and spin-forbidden d-d transition spectra. These assignments are in good agreement with those of DeKock and Gruen (16, 18) and Smith (15) but differ from those of Hougen et al. (19).

Enthalpy of Formation

Kustodina et al. (1) derived the enthalpy of formation of Cl_2O dissolved in CCl_4 from solution calorimetry at 278, 283, 298 and 308 K. The enthalpy of formation in CCl_4 was interpolated to 285 K. Yost and Felt (2) measured the partial vapor pressures of Cl_2O above its CCl_4 solution at 273 and 298 K which yield the heat of solution -6.59 kcal mol^{-1} at 285 K. The $\Delta_f H°(298.15\ K)$ = 21.0 kcal mol^{-1} was calculated from these two values. Wallace and Goodeve (3) obtained the heat of explosion of $Cl_2O(g)$: their data give $\Delta_f H°(Cl_2O, g, 298.15\ K)$ = 21.4 kcal mol^{-1} which is in very good agreement with the above. Also Gunther and Wekua (4) measured the enthalpy of explosion; their data give $\Delta_f H°(Cl_2O, g, 298.15\ K)$ = 24.7 kcal mol^{-1}.

Source	Reaction	T/K	$\Delta_r H°(T)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	$Cl_2(g) + 1/2\ O_2(g) + Cl_2O_{(in\ CCl_4)}$	285	14.38	-
(2)	$Cl_2O_{(in\ CCl_4)} + Cl_2O(g)$	285	6.59	21.0
(3)	$Cl_2O(g) + Cl_2(g) + 1/2\ O_2(g)$	298	-21.4	21.4
(4)	$Cl_2O(g) + Cl_2(g) + 1/2\ O_2(g)$	298	-24.7	24.7

Heat Capacity and Entropy

The vibrational frequencies were obtained from Rochkind and Pimentel (5). The infrared spectrum of $Cl_2O(g)$ has been investigated previously beginning with the work of Bailey and Cassie (6). Hedberg (7) proposed stretching frequencies at 688 cm^{-1} (ν_1) and 969 cm^{-1} (ν_3) but left the bending frequency unknown. Previous evidence concerning the bending mode (ν_2) (9) was shown by Hedberg (7) to be spurious. Rochkind and Pimentel (5) present infrared studies of Cl_2O gas and condensed phases which reveal the bending frequency and require reassignment of the stretching fundamentals. The bond distance and bond angle were obtained from Dunitz and Hedberg (8).

The principal moments of inertia are: $I_A = 2.0224 \times 10^{-39}$, $I_B = 23.0829 \times 10^{-39}$ and $I_C = 25.1033 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weights: [1] σ = 2
Point Group: [C_{2v}]
Bond Distances: O-Ti = [1.62] Å Ti-Cl = [2.20] Å
Bond Angle: O-Ti-Cl = [120]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [4.63214 x 10^{-113}] g^3 cm^6

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as -130 kcal mol^{-1} by Gordon (1). $\Delta_f H°(298.15\ K)$ was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon (1). Principal moments of inertia are: I_A = 17.8783 x 10^{-39} g cm^2, I_B = 42.7411 x 10^{-39} g cm^2, and I_C = 60.6194 x 10^{-39} g cm^2.

Enthalpy of Formation

The adopted $\Delta_f H° = -84.8 \pm 0.5$ kcal mol^{-1} is based on Kp for dissociation to SO_2 and Cl_2 (see below). The relatively thorough study of Arii (2) gave similar values of Kp near the pressure of SO_2Cl_2 and at reduced pressures. The entropy discrepancy is large ($\delta S = -11$ cal K^{-1} mol^{-1}), but this may be due to the small temperature range and to uncertainties in absorption on the activated charcoal catalyst. Absorption uncertainties probably exist in all of the Kp studies, but the high-temperature data of Trautz (3) have an additional uncertainty; i.e., Kp is very sensitive to small systematic errors in the data since the SO_2Cl_2 is almost completely decomposed. Exclusion of data (3) above 416 K yields a 3rd law $\Delta_r H°$ which agrees satisfactorily with Arii (2). Data of Londergan (1) yield a 3rd law $\Delta_r H°$ which is smaller by about 0.4 kcal mol^{-1}; these data yield almost no entropy discrepancy, but the experimental method (1) appears to be less satisfactory.

The adopted $\Delta_f H°$ is consistent with old calorimetric data of Thomsen (5) for hydrolysis of the liquid but inconsistent with recent data of Neale and Williams (4), on which the selections of NBS 270-3 (6) are probably based. Consistency tests require $\Delta_v H$; thus, we note that in the absence of a catalyst $SO_2Cl_2(g)$ persists to well above the boiling point even though it is unstable with respect to SO_2 and Cl_2. Evidence for this conclusion includes studies of catalysts (3, 7), vapor densities (8), boiling point and vapor pressures (9, 10, 7). The boiling point (69.5 ± 0.3°C) and $\Delta_{vap}S$ (20.8 cal K^{-1} mol^{-1}) are almost exactly those predicted by comparison with SO_2ClF (7.3°C and 20.6 cal K^{-1} mol^{-1}) and SO_2F_2 (-55.3°C and 21.1 cal K^{-1} mol^{-1}), which have normal vapors. Vapor pressure data (9) for SO_2Cl_2 yield $\Delta_v H = 7.1$ kcal mol^{-1} at 69.5°C and $\Delta_v H° = 7.8$ kcal mol^{-1} at 25°C. Trautz et al. (10) used a condensation method to measure $\Delta_{vap}H = 6.67$ kcal mol^{-1} near Tb, but we dismiss this value since the resulting $\Delta_{vap}S$ (19.5 cal K^{-1} mol^{-1}) is too small for normal vapor and much too small for dissociating vapor.

[c] Calorimetric $\Delta_r H$ adjusted to 25°C.

Heat Capacity and Entropy

Bond lengths and bond angles are those derived from new electron-diffraction data by Hargittai (11). These differ significantly from early results of Palmer (12). Microwave spectra were reported by Abbar (13), but structural parameters were not derived from the data. The adopted structure has an O-S-Cl angle of 107.7° and principal moments of inertia of $I_A = 24.0520 \times 10^{-39}$, $I_B = 36.0706 \times 10^{39}$ and $I_C = 43.8672 \times 10^{39}$ g cm^2.

The vibrational assignment is from force-constant calculations of Toyuki and Shimizu (14). Pfeiffer's assignment (15) is only slightly different and results in negligible change in the thermodynamic functions. Spectral data were summarized by Gillespie and Robinson (16) in their study of the liquid-phase Raman spectra. Only those frequencies above 500 cm^{-1} are based on gas-phase spectra. Trautz et al. (10) found Cp = 15.4 ± 0.3 J K^{-1} mol^{-1} by calorimetry at 43 mmHg and 16 to 99°C; this Cp is too low, like $\Delta_{vap}H$ (10), and the error is almost 20%.

PREVIOUS: June 1971 (1 atm) CURRENT: June 1971 (1 bar)

TUNGSTEN CHLORIDE OXIDE (WO_2Cl_2) CRYSTAL M_r = 286.7548

$S°(298.15\ K) = [200.832]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -780.32 \pm 5.9\ kJ\ mol^{-1}$

Enthalpy of Formation

Shchukarev et al. (1) measured calorimetrically the enthalpies of reaction (1) and (2) at 298.15 K at -67.3±0.2 and -13.6±0.11 kcal mol^{-1}, respectively. The reactions are given as follows: (1) $WO_2Cl_2(cr) + 4\ NaOH(aq, 16.3\ H_2O) \rightarrow Na_2WO_4(aq, 80000\ H_2O) + 2\ NaCl(aq, 40000\ H_2O) + 2\ H_2O(\ell)$ and (2) $H_2WO_4(cr) + 2\ NaOH(aq, 16.3\ H_2O) \rightarrow Na_2WO_4(aq, 20000\ H_2O) + 2\ H_2O(\ell)$.

Based on these data and the enthalpies of dilution for NaOH(aq), NaCl(aq) and $Na_2WO_4(aq)$, we obtain $\Delta_r H°(298.15\ K)$ = 53.77±1.0 kcal mol^{-1} for $WO_2Cl_2(cr) + 2\ OH^-(aq, \infty) \rightarrow H_2WO_4(cr) + 2\ Cl^-(aq,\infty)$. This leads to $\Delta_f H°(WO_2Cl_2, cr, 298.15\ K)$ = -186.5 kcal mol^{-1} using $\Delta_f H°(H_2WO_4, cr, 298.15\ K)$ = -270.5±0.4 kcal mol^{-1}.

Heat Capacity and Entropy

$C_p°(300)$ = 25.0 cal K^{-1} mol^{-1} is estimated using Kopp's rule. Heat capacities at higher temperature are estimated from those of $WO_2(cr)$, $WO_3(cr)$, $WCl_6(cr)$. The entropy $S°(298.15\ K)$ = 48.0 cal K^{-1} mol^{-1} is calculated from $\Delta S°(598.6\ K)$ = 32.27±1.3 cal K^{-1} mol^{-1} for $WO_2Cl_2(cr) \rightarrow WO_2Cl_2(g)$. The value of $\Delta S°(598.6\ K)$ is obtained from the 2nd law analysis of the vapor pressure data given by Shchukarev and Suvorov (4).

Decomposition Data

Shchukarev and Suvorov (4) found that $WO_2Cl_2(cr)$ does not melt but decomposes. The saturated vapor over $WO_2Cl_2(cr)$ consists mainly of $WOCl_4(g)$ which will disproportionate to form $WO_2Cl_2(g)$ and $WCl_6(g)$. The estimated T_{dcm} = 642 K is derived by interpolation to one atmosphere in the total pressures of $WOCl_4(g)$, $WO_2Cl_2(g)$ reported by Shchukarev and Suvorov (4).

Point Group: [C_{2v}]
Bond Distances: W-Cl = [2.26] Å W-O = [1.81] Å
Bond Angles: Cl-W-Cl = [113]° O-W-O = [109.47]° O-W-Cl = [90]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [1.16512 x 10^{-112}] $g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(WO_2Cl_2, g, 298.15\ K) = -160.5\ kcal\ mol^{-1}$ is obtained from $\Delta_r H°(298.15\ K) = 26.0\ kcal\ mol^{-1}$ for $WO_2Cl_2(cr) + WO_2Cl_2(g)$. The latter is calculated by the 3rd law method from the partial pressures of $WO_2Cl_2(g)$ given by Shchukarev and Suvorov (6). 2nd law analysis gives $\Delta_r H°(598.6\ K) = 24.1 \pm 0.8\ kcal\ mol^{-1}$ $\Delta_r H°(298.15\ K) = 26.0\ kcal\ mol^{-1}$. These reported partial vapor pressures of $WO_2Cl_2(g)$ were derived by the optical tensimetric method from total pressures over $WO_2Cl_2(cr)$ considering the species $WOCl_4(g)$, $WO_2Cl_2(g)$ and $WCl_6(g)$. Since the decomposition of $WO_2Cl_2(cr)$ was very complicated, we tentatively assign 6 kcal mol^{-1} uncertainty to the adopted enthalpy of formation.

Shchukarev and Suvorov (6) have also derived a log Kp equation for the disproportionation process, $2\ WOCl_4(g) = WO_2Cl_2(g) + WCl_6(g)$. 3rd law analysis gives $\Delta_r H°(298.15\ K) = 10.3\ kcal\ mol^{-1}$ for the above process. This leads to $\Delta_f H°(WO_2Cl_2, g, 298.15\ K) = -145.7 \pm 16\ kcal\ mol^{-1}$. The 2nd law $\Delta_r H°(590\ K)$ is 11.0 kcal mol^{-1} $\Delta_r H°(298.15\ K) = 10.1\ kcal\ mol^{-1}$. The drift in the 3rd law analysis is 0.3 cal $K^{-1}\ mol^{-1}$.

Heat Capacity and Entropy

The molecular configuration is assumed to be a distorted tetrahedron of C_{2v} symmetry, similar to that of $MoO_2Cl_2(g)$ (1), and $CrO_2Cl_2(g)$ (2). The bond distances W-O and W-Cl are estimated to be the same as those in $WO_3(g)$ and $WCl_6(g)$, respectively. The bond angles are assumed to be the same as those in $MoO_2Cl_2(g)$ (1). The principal moments of inertia are: $I_A = 33.9761 \times 10^{-39}$, $I_B = 53.4238 \times 10^{-39}$ and $I_C = 64.1894 \times 10^{-39}\ g\ cm^2$.

The vibrational frequencies, 984 cm^{-1} and 972 cm^{-1}, were observed in the infrared spectra Barraclough and Stals (3). They tentatively assigned these two as the symmetric and asymmetric W-O stretching frequencies. The rest of the frequencies are estimated by comparison with those observed in the infrared and Raman spectra for $CrO_2Cl_2(g)$ (4, 5). They are not listed in point group order.

$S°(298.15\ K) = 135.98 \pm 2.1\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 774\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -359.4 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 21.88 \pm 0.84\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ of -85.9 ± 0.2 kcal mol^{-1} is obtained from a 3rd law analysis of six sets of electromotive force data (3, 4, 6, 7) for three different reactions, namely, (A) Pb(cr) + 2 AgCl(cr) = 2 Ag(cr) + $PbCl_2$(cr), (B) Pb(cr) + Hg_2Cl_2(cr) = 2 Hg(ℓ) + $PbCl_2$(cr), and (C) Pb(ℓ) + Cl_2(g) = $PbCl_2$(cr). Seven other sets of similar data (1, 2, 5) give $\Delta_f H°$ values which are within ±0.2 kcal mol^{-1} of adopted value, while one set of emf data (7) for (D) 2CuCl(cr) + Pb(cr) = $PbCl_2$(cr) + 2 Cu(cr) gives a $\Delta_f H°$ value of -85.4 kcal mol^{-1}. A $\Delta_f H°$ value can be obtained also from a 3rd law analysis of equilibrium data (8) for (E) $PbCl_2$(cr) + H_2(g) = Pb(ℓ) + 2 HCl(g). Auxiliary enthalpies of formation used in our analysis are $\Delta_f H°(298.15\ K)$, kcal mol^{-1}: AgCl, cr, = -30.370 (9), CuCl, cr = -33.0 ± 0.4 (10), Pb, ℓ = 1.025 (10), Hg_2Cl_2, cr = -63.319 ± 0.05 (10) and HCl, g = -22.063 ± 0.05 (10). We assign an uncertainty of ±0.2 kcal mol^{-1} to $\Delta_f H°$ to reflect the estimated error in the adopted value for S°(298.15 K).

Heat Capacity and Entropy

$C_p°$ data below 298.15 K have been reported by Nerst (15.6-87.7 K, 11), Eucken (106.5-290.7 K, 12), and Bronsted (283 K, 13). We combine these results with $C_p°$ = 18.52 cal K^{-1} mol^{-1} (14) at 330 K and obtain S°(298.15 K) = 33.7 cal K^{-1} mol^{-1} based on S°(15.6 K) = 0.9 cal K^{-1} mol^{-1}. Kelley and King (15) analyzed the same $C_p°$'s and found S°(298.15 K) = 34.0 ± 1.0 cal K^{-1} mol^{-1}. Data obtained from cell measurements on both the crystal and liquid allow independent calculations of S°(298.15 K). Thirteen of the 23 sets of emf data htat we have analyzed are more compatible with a value for S°(298.15 K) which is at least one cal K^{-1} mol^{-1} less than that determined from the low temperature data. Since the cell measurements are judged to be more reliable, we adopt S°(298.15 K) = 32.5 ± 0.5 cal K^{-1} mol^{-1} and omit the $C_p°$ data below 298.25 K.

$C_p°$'s above 300 K are based on the smoothed relative enthalpies of Alim et al. (16). Their measurements were made in an isothermal diphenyl ether calorimeter over the temperature range 400 to 950 K. The $PbCl_2$ was reported to have a purity of 99.96%, and samples of this material were sealed in platinum capsules for the drop experiments. Their enthalpies are fitted to a polynomial which represents the data to within ±0.4%. The calculated $C_p°$'s above 300 K are joined graphically with those of Eucken (12) at 298.15 K by comparison with the $C_p°$-T curve for $BaCl_2$(cr) (10). Our adopted enthalpies are in reasonable agreement with those of Kelley (17). His results are based on the enthalpy measurements of Krestovnikov and Karetnikov (18), and most of the points agree with ours to better than a percent but show a maximum deviation of -1.3% at 500 K. Other enthalpy data that have been recently reported are those of Bloom and Tricklebank (693-773 K, 19) and Thompson and Flengas (577-745 K, 20). Both of these studies show rather poor agreement with our adopted results. Deviations from our values are -4.2% at 673 K to -5.0% at 773 K for (19), -0.1% at 680 K and -6.2% at 745 K for (20). Both drop investigations were conducted with quartz capsules which might have been slowly attacked by the $PbCl_2$ at the higher temperatures. The earlier enthalpy measurements of Goodwin and Kalmus (21) are considered less reliable and not included in our analysis.

Modestova (22) has reported the existence of a transition for $PbCl_2$ at 695 K based on differential thermal analysis and x-ray studies. This transition has not been observed by other workers, and we prefer not to include it. However, if it does exist, we speculate that the enthalpy associated with it is quite small; thus, our functions would be only slightly altered.

Fusion Data

T_{fus} = 774 K is from the enthalpy study of Alim et al. (16). Other values reported for T_{fus} based on enthalpy measurements are 771 (21), 774 (18), 774 (19) and 772 (20). DTA measurements (24) gave T_{fus} equal to 774 K, while cryoscopic studies (23) yielded 768 K. $\Delta_{fus} H°$ is calculated to be 5.23 kcal mol^{-1} from the adopted enthalpies for the crystal and liquid at T_{fus}. Published values (all in kcal mol^{-1}) include 5.15 (21), 5.70 (23), 2.98 (18), 5.3(19), 5.56 (20), and 5.03 (24).

Sublimation Data

See the ideal gas table for details.

$S°(298.15\ K) = [153.396]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 774\ K$

$\Delta_f H°(298.15\ K) = [-344.251]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 21.88 \pm 0.84\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(PbCl_2, \ell, 298.15\ K)$ is calculated from that of the crystal by addition of $\Delta_{fus}H°$ and the difference in enthalpy, $H°(774\ K)-H°(298.15\ K)$, between the crystal and liquid. Independent values of $\Delta_f H°(\ell)$ (or $\Delta_f H°(cr)$) can be obtained from a 2nd and 3rd analysis of nine sets of emf data (1-9) for the formation cell of molten $PbCl_2$ ((A) $Pb(\ell) + Cl_2(g) = PbCl_2(\ell)$) and three sets of equilibrium data (10, 11) for (B) $PbCl_2(\ell) + H_2(g) = Pb(\ell) + 2\ HCl(g)$. Auxiliary enthalpies of formation used in the analysis are $\Delta_f H°(Pb, \ell, 298.15\ K) = 1.025\ kcal\ mol^{-1}$ (12) and $\Delta_f H°(HCl, g, 298.15\ K) = -22.063 \pm 0.05\ kcal\ mol^{-1}$ (12). Five of the nine sets of emf data yield values for $\Delta_f H°(cr)$ which are in good agreement ($\pm 0.2\ kcal\ mol^{-1}$) with the adopted value. Also, the results of the extensive emf measurements of Warner and Seifert (8) by the electronic commutator method are quite compatible with our adopted functions.

Heat Capacity and Entropy

$C_p°$ is assumed constant at 26.65 cal K^{-1} mol^{-1} over the temperature range 500-2000 K and is based on the smoothed relative enthalpies (774-950 K) of Alim et al. (13). A glass transition is assumed at 500 K below which $C_p°$ is that of the crystal. The smoothed enthalpies of Kelley (14) (800-1000 K) deviate by +4.0% from our values, while those of Thompson and Flengas (15) (813-945 K) deviate by ±1%. The enthalpies of Bloom and Tricklebank (16) are consistently lower than our values by -3.1% at 823 K, and the deviation increases to -12.6% at 1073 K. Warner and Seifert (8) have determined $C_p°$ data for $PbCl_2(\ell)$ from their emf measurements. They reported values of (all in cal K^{-1} mol^{-1}) 25.7 (800 K), 26.2 (900 K), 26.5 (1000 K) and 26.7 (1100 K). Bizouard and Pauty (17) measured $C_p°$ for the liquid as 24.7 cal K^{-1} mol^{-1}. $S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Vaporization Data

T_{vap} is the temperature at which $\Delta_r G° = 0$ for the process $PbCl_2(\ell) \rightarrow PbCl_2(g)$. $\Delta_{vap}H°$ is calculated as the difference between the enthalpies of formation of the gas and liquid at T_{vap}.

Enthalpy of Formation

$\Delta_f H°$ of -41.6 ± 0.3 kcal mol^{-1} is obtained from $\Delta_f H°(cr)$ = -85.9 ± 0.2 kcal mol^{-1} by addition of $\Delta_{sub}H°(298.15\ K)$. The adopted value for $\Delta_{sub}H°(298.15\ K)$ is 44.3 ± 0.1 kcal mol^{-1} and is based on a 3rd law analysis of six sets of vapor pressure data (4, 9, 11, 14, 15) for both the crystal and liquid. Results of our analysis of a total of eighteen sets of Vp data are given below. Seven (1, 2, 3, 7, 8, 10, 12) of the remaining twelve sets yield $\Delta_f H°(g)$ values which are within 0.3 kcal mol^{-1} of the adopted value. Mass spectrometric studies (16) of the equilibrium vapors over the condensed phases indicated that the predominant species is the monomer.

Heat Capacity and Entropy

The bond length is taken from the electron diffraction study of Lister and Sutton (17). Electric deflection experiments by Buchler et al. (18) showed that $PbCl_2$ possessed a permanent dipole moment; thus, the molecule must have a bent structure. Infrared studies (19) of matrix isolated $PbCl_2$ have led to a value for the bond angle of 96 ± 3° which we adopt. This value is based on the observed Cl isotopic splitting of the antisymmetrical stretching frequency (ν_3). The principal moments of inertia are: $I_A = 23.7690 \times 10^{-39}$, $I_B = 39.3510 \times 10^{-39}$, and $I_C = 63.1200 \times 10^{-39}$ g cm^2.

The vibrational frequencies are from the matrix infrared studies of Hastie et al. (19). Both of the stretching frequencies (ν_1 and ν_3) were observed in matrices of N_2, Ar, and Ne. The adopted values are gas-phase frequencies which were estimated by Hastie et al. (19) from their matrix data. Other matrix infrared (20) and matrix Raman (21) studies have led to stretching frequencies which deviate by less than 30 cm^{-1} from our adopted values. Also, ν_1 is in agreement with the value of 314 cm^{-1} which was observed by Beattie and Perry (22) in a gas-phase Raman study at 1000°C. The bending frequency (ν_2) is somewhat more uncertain that the stretching frequencies. Hastie et al. (19) observed a relatively weak band at 80 cm^{-1} when $PbCl_2$ was trapped in a neon matrix and assigned this band to ν_2. Gas-phase (22) and matrix (21) Raman studies have indicated that ν_2 lies much closer to 100 cm^{-1}. The gas-phase Raman spectrum (22) was obtained in the presence of an excess of chlorine to suppress decomposition and subsequent resonance fluorescence. We prefer the lower value (80 cm^{-1}) but assign an uncertainty of ±20 cm^{-1} which corresponds to 0.5 cal K^{-1} mol^{-1} in S°(298.15 K).

The ground state is assumed to be $^1A_1$ based on an analogy with those for other Group IV A dichlorides (23). The upper $^1B_1$ level at 31000 cm^{-1} was observed by Hastie et al. (23). Also included is a triplet level ($^3B_1$) at 22000 cm^{-1}. The energy separation for the $^1B_1$-$^3B_1$ states (9000 cm^{-1}) is assumed to be similar to that observed for other Group IV A dichlorides (23).

Enthalpy of Formation

The appearance potential for $PbCl_2^+$ from $PbCl_2(g)$ has been determined spectrometrically as (in eV) 11.2±0.2 (1), 10.3±0.2 (2) and 10.3±0.5 (3). Hastie et al. (2) preferred the lower AP for $PbCl_2^+$, since this value was obtained with more sensitive equipment. Subsequent measurements by Hastie and Swingler (4) confirm the lower result. They reported an ionization efficiency curve for $PbCl_2^+$ from which we obtain AP = 10.0 eV by the linear extrapolation method. Also, molecular orbital calculations by Hastie and Margrave (5) indicated $IP(PbCl_2,g)$ = 10.3 eV. We adopt a mean value from (2, 3, and 4) of 10.2±0.5 eV (235.2 kcal mol^{-1}) for the process $PbCl_2(g) + e^- \rightarrow PbCl_2^+(g) + 2\ e^-$ which gives $\Delta_f H°(PbCl_2^+, g, 0\ K) = 194.1 \pm 12.0$ kcal mol^{-1} when AP is combined with $\Delta_f H°(PbCl_2, g, 0\ K) = -41.1 \pm 0.3$ kcal mol^{-1} (6). $\Delta_f H°(298\ K) = 195.1$ kcal mol^{-1}.

Heat Capacity and Entropy

The correlation diagram of Walsh (7) predicts a bent configuration for $PbCl_2^+$, since the molecule has seventeen valence electrons. Also, Walsh (7) predicted that the apex angle for a non-hydride AB_2 molecule would decrease markedly in going from a 17- to an 18- electron molecule. We assume that the bond angle in $PbCl_2^+$ is 20° larger than that for $PbCl_2$ (6). The adopted value (116°) is consistent with JANAF bond angles for the isoelectronic molecules BCl_2(112°) and $AlCl_2$(120°) (6). The bond length is assumed to lie between that for PbCl and $PbCl_2$ (6). The principal moments of inertia are: $I_A = 13.0315 \times 10^{-39}$, $I_B = 44.7956 \times 10^{-39}$ and $I_C = 57.8271 \times 10^{-39}$ g cm^2.

The vibrational frequencies are estimated by comparison with those for BCl_2, CCl_2, $SiCl_2$, and $PbCl_2$ (6). The ground state is assumed to be $^2A_1$ by analogy with that for the isoelectronic molecule NO_2 (8). MO calculations by Hastie and Margrave (5) for the Group III A dihalides predicted an upper $^2B_1$ state with the $^2A_1$-$^2B_1$ separation in the energy range 1-2 eV. We have included this state and estimated the $^2A_1$-$^2B_1$ separation (20,000 cm^{-1}) to be somewhat greater than that for AlO_2 (15,000 cm^{-1}) (6), BCl_2 (11,000 cm^{-1}) (6) and NO_2 (<15,000 cm^{-1}) (8).

PREVIOUS: June 1973 (1 atm) CURRENT: June 1973 (1 bar)

$S°(298.15\ K) = 183.678 \pm 4.2\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = -49.79 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Trautz and Hoffmann (1) have measured calorimetrically the enthalpy of solution of gaseous chlorine in liquid dichlorodisulfane at 298.15 K. They reported $\Delta_{sln}H° = -9.8 \pm 0.4$ kcal mol^{-1} for a final state consisting of SCl_2 dissolved in an excess of S_2Cl_2. Combining their measured $\Delta_{sln}H$ value with $\Delta_f H°(S_2Cl_2, \ell, 298.15\ K) = -13.9 \pm 0.5$ kcal mol^{-1} (2), we obtain the adopted result of $\Delta_f H°(SCl_2, \ell, 298.15\ K) = -11.9 \pm 0.5$ kcal mol^{-1}. In arriving at this value, no enthalpy corrections are applied for dissolution of the SCl_2 in the excess S_2Cl_2 and for the temperature difference since we expect both corrections to be small and they tend to cancel. Our adopted value agrees with the selected values of NBS (-12 kcal mol^{-1}, 3) and Mills (-11.8 kcal mol^{-1}, 4).

Heat Capacity and Entropy

The heat capacity of liquid SCl_2 is estimated as 21.75 cal K^{-1} mol^{-1} using the value of 7.25 cal K^{-1} g-atom^{-1} recommended by Kubaschewski et al. (5). This estimated value of $C_p°$ corresponds to a specific heat of 0.21 cal g K^{-1} which agrees with the experimentally measured value for S_2Cl_2 of 0.22 cal g K^{-1} (2). We assume that $C_p°$ is constant in the temperature range 298-800 K. The value of S°(298.15 K) is selected as 43.9±1.0 cal K^{-1} mol^{-1} which minimizes differences between the second and third law entropies of vaporization determined from vapor pressure data (6) on a pure stabilized sample of SCl_2. Further details on the results of these analyses can be found in the heat of formation section of the $SCl_2(g)$ table (2).

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy of vaporization becomes zero. The value of $\Delta_{vap}H°$ is calculated as the difference between the $\Delta_f H°$ values for the gas and liquid at T_{vap}. The experimental value of T_{vap} determined from vapor pressure measurements is 332.7 K (6).

Enthalpy of Formation

Rosser and Whitt (1) have reported the results of a vapor pressure study of SCl_2. Measurements were conducted on a sample of SCl_2 stabilized with PCl_3 to suppress decomposition. Using JANAF free energy functions (2), we analyze their vapor pressure points (1) lying above 298 K by the second and third law methods. In the analysis we select $S°(SCl_2, \ell, 298.15\ K) = 43.9\ cal\ K^{-1}\ mol^{-1}$ which minimizes the difference between the 2nd and 3rd law entropies of vaporization. Our results are $\Delta_{vap}H°$ (2nd law) = $\Delta_{vap}H°$ (3rd law) = 7.75±0.02 kcal mol^{-1} which leads to the adopted heat of formation of $\Delta_f H°(SCl_2, g, 298.15\ K) = -4.2 \pm 0.8$ kcal mol^{-1} when combined with $\Delta_f H°(SCl_2, \ell, 298.15\ K) = -11.9 \pm 0.5$ kcal mol^{-1} (2). The adopted value of $\Delta_f H°$ is rounded to the nearest 0.1 kcal mol^{-1}. The overall uncertainty is estimated as ±0.8 kcal mol^{-1} based on contributions from the uncertainty in $\Delta_f H°$ of *the liquid (±0.5 kcal mol^{-1}) and from the uncertainty in the entropy (±1.0 cal K^{-1} mol^{-1})* of the liquid (2) which amounts to roughly 0.3 kcal mol^{-1} in $\Delta_f H°$.

Barton and Yost (3) have studied the dissociation of $S_2Cl_2(g)$ at various temperatures. Their measured dissociation data above 760 K have been reanalyzed by Yost and Russell (4) who have determined equilibrium constants for the reactions (a) $S_2(g) + Cl_2(g) = S_2Cl_2(g)$ and (b) $0.5S_2(g) + Cl_2(g) = SCl_2(g)$ by combining the dissociation pressures with molecular data and an estimated value for the $\Delta_f H°$ of SCl_2. Second and third law analyses of the equilibrium data for reaction (b) give $\Delta_r H°(298.15\ K)$ (2nd law) = $\Delta_r H°(298.15\ K)$ (3rd law) = -20.69±0.01 kcal mol^{-1} which corresponds to $\Delta_f H°(SCl_2, g, 298.15\ K) = -5.3$ kcal mol^{-1} using the recent JANAF (2) value of $\Delta_f H°$ for $S_2(g)$. This $\Delta_f H°$ value for $SCl_2(g)$ is some 1.1 kcal mol^{-1} more negative than that obtained from an analysis of vapor pressure data described above. We find a similar discrepancy in the equilibrium data for reaction (a) where the derived $\Delta_f H°$ value of $S_2Cl_2(g)$ is 3 kcal mol^{-1} more negative than that obtained from an analysis of vapor pressure data. (See $S_2Cl_2(g)$ table for details). We conclude that the equilibrium constants reported by Yost and Russell (4) are biased, and we give no weight to the $\Delta_f H°$ values derived from their data.

Values of $\Delta_f H°$ previously selected by Colwell (5) and Mills (6) have been based primarily on the equilibrium data of Yost and Russell (4). The value selected by NBS (7) is -4.7 kcal mol^{-1}. Our adopted results give an enthalpy of atomization and mean S-Cl bond dissociation energy of 126.8±0.9 kcal mol^{-1} and 63.4 kcal mol^{-1}, respectively.

Heat Capacity and Entropy

Early electron diffraction studies (8, 9) and more recent microwave measurements (10, 11) have shown that the SCl_2 molecule has C_{2v} symmetry. We adopt structural parameters from the microwave work of Davis and Gerry (11). The bond length and angle refer to an average structure of $^{32}S^{35}Cl_2$ in the (000) vibrational state obtained from a quadratic potential function based solely on microwave data (11). This average structure is only slightly different from the effective structure determined by Murray et al. (10) but quite different from the molecular structure derived from electron diffraction measurements (8, 9) which are considered less accurate. The symmetrical stretch (ν_1) and bending (ν_2) frequencies are those observed by Frankiss and Harrison (12) in the Raman spectra of the vapor at 335 K. The asymmetrical stretching frequency (ν_3) was not detected in this recent Raman study (12) and still remains relatively uncertain (±10 cm^{-1}). We use ν_3 = 525 cm^{-1} based on the infrared measurements of Savoie and Tremblay (13), as suggested by Frankiss and Harrison (12). The electronic levels and configurations are taken from the *CNDO/2 MO* calculations and electronic absorption spectral measurements of Colton and Rabalais (14). The principal moments of inertia are: $I_A = 5.8026 \times 10^{-38}$, $I_B = 29.1706 \times 10^{-38}$, and $I_C = 34.9733 \times 10^{-39}\ g\ cm^{-2}$.

Our ideal gas thermal functions are essentially an extension of those previously published by Frankiss and Harrison (12) who also reviewed data published prior to their paper. All earlier functions require revision since they are based on liquid state vibrational frequencies and the molecular structure determined by electron diffraction.

Enthalpy of Formation

$\Delta_f H°(0\ K)$ is calculated from IP = 9.46±0.02 eV by addition of the JANAF $\Delta_f H°(0\ K)$ value for SCl_2 (1). The selected value of IP is calculated as the adiabatic IP from the first band system observed in the HeI photoelectron spectrum of SCl_2 by Solouki et al. (2). The adiabatic IP is 0.21 eV less than the vertical value determined by photoelectron spectroscopy (2) and 0.24-0.74 eV less than the vertical IP's measured by electron impact (3, 4).

$\Delta_f H°(298.15\ K)$ is obtained from the adopted $\Delta_f H°(0\ K)$ value by using JANAF enthalpies (1) for S(α, cr), Cl_2(g), and e^-(g). $\Delta_r H°(298.15\ K)$ determined for the direct ionization $SCl_2 = SCl_2^+ + e^-$ from our tables differs from a room-temperature threshold energy due to inclusion of the enthalpies of all the species in this ionization process and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by -1.481 kcal mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

We perform bond energy calculations which show that the S-Cl primary bond dissociation energy for SCl_2^+ (66.6 kcal mol^{-1}) is quite similar to that for the neutral dichloride (69.7 kcal mol^{-1}), indicating that the removal of the electron during ionization should produce minimal structural changes. According to the Walsh diagram (6) for AB_2 molecules, the most loosely bound electron in SCl_2 occupies a $4b_1$ orbital which is S-Cl antibonding and Cl-Cl bonding. Thus, we would expect a slight increase in the bond angle and a decrease in the S-Cl bond distance upon removing this electron to form SCl_2^+. We estimate the Cl-S-Cl bond angle as 105° (102.7° for SCl_2) and the S-Cl bond distance as 2.00 Å (2.015 Å for SCl_2. Based on this estimated structure, the principal moments of inertia are: $I_A = 5.4345 \times 10^{-39}$, $I_B = 29.6437 \times 10^{-39}$, and $I_C = 35.0782 \times 10^{-39}$ g cm.

The photoelectron spectrum of SCl_2 has been measured by Solouki et al. (2) who reported observing a vibrational spacing of 530±30 cm^{-1} in the first band system. They assigned this progression to the S-Cl symmetric stretching frequency ν_1. By analogy with the observed vibrational frequencies for SCl_2 (1), the difference between ν_1 and ν_3 is expected to be small. We adopt $\nu_1 = \nu_3 = 530\ cm^{-1}$, and we estimate the bending frequency to be 5 cm^{-1} lower than that for SCl_2 (205 cm^{-1}, 1).

The electronic configurations of the ground and excited states are predicted from Walsh's empirical diagram (6) which correlates well with the observed photoelectron spectra and calculated orbital energies for the related dihalide molecules SCl_2(2), OCl_2, and OF_2 (7). We use relative term values for three of the four predicted states calculated from the vertical ionization energies reported by Solouki et al. (2). We include a second $^2A_1$ state at 21000 cm^{-1} based on the fact that this state has been observed in the PE spectrum of OCl_2 (7), lying 2258 cm^{-1} above the first $^2A_1$ state. Inclusion of this state is also supported by the results of orbital energy calculations (2) on SCl_2. The enthalpy between 0 K and 298.15 K is -2.9764 kcal mol^{-1}.

PREVIOUS: June 1978 (1 atm) CURRENT June 1978 (1 bar)

$S°(298.15\ K) = 223.844 \pm 4.2\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = -58.158 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Feher and Strater (1) have measured calorimetrically the heats of chlorination of sulfur and liquid dichlorodisulfane at 298.15 K. Recalculation of their calorimetric data using 1975 atomic weights (2) and a $\Delta C_p°$ of 10.80 cal K^{-1} mol^{-1} for the formation reactions $2S(rh) + Cl_2(g) \rightarrow S_2Cl_2(l)$ leads to the adopted $\Delta_f H°$ of -13.9±0.5 kcal mol^{-1}. (-58.158 ± 2.1 kJ mol^{-1}).

Other calorimetric values for $\Delta_f H°$ which were published prior to 1930 have been recently summarized by Mills (3). Two of these four values, which range from -14.3 to -17.6 kcal mol^{-1}, agree with the adopted $\Delta_f H°$ value within the combined experimental error. Our selected value agrees with that from Mills (3) but is some 0.3 kcal mol^{-1} less negative than the value (-14.2 kcal mol^{-1}) recommended by NBS (4).

Heat Capacity and Entropy

$C_p°$ has been measured calorimetrically as 29.706 cal K^{-1} mol^{-1} by Trautz and Rick (5) at 295.15 K and by Ogier (6) as the mean $C_p°$ value over the temperature range 285-343 K. We adopt this value and assume $C_p°$ is constant from 298.15 K to 1000 K. The value of $S°(298.15\ K)$ is selected as 53.5±1.0 cal K^{-1} mol^{-1} which minimizes differences between the second and third law entropies of vaporization determined from two independent sets (7, 8) of vapor pressure data. Further details on the results of these analyses can be found in the heat of formation section of the S_2Cl_2 gas phase table (9).

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy of vaporization becomes zero. The value of $\Delta_{vap}H°$ is calculated as the difference between the $\Delta_f H°$ values for the gas and liquid at T_{vap}. Experimental values of T_{vap} determined from vapor pressure measurements include 411 K (7) and 408.9 K (8).

Enthalpy of Formation

Harvey and Schuette (1) and Trautz et al. (2) have used a static method to measure vapor pressures for liquid S_2Cl_2 at various temperatures below the normal boiling point. Barton and Yost (3) measured the extent of dissociation for gaseous S_2Cl_2 above 760 K. These dissociation data have been reanalyzed by Yost and Russell (4) who reported equilibrium constants for the reaction $S_2(g) + Cl_2(g) = S_2Cl_2(g)$. We analyze these data by the 2nd and 3rd law methods with the results presented below:

Source	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	A	12[a]	304-411	9.46	9.89±0.07	1.1±0.2	4.01
(2)	A	Set 1 20[b]	374-410	10.0	9.93±0.01	-0.1±0.2	3.97
		Set 2 39[c]	329-374	10.15	9.95±0.02	-0.6±0.1	3.95

(4)	B	Equation	760-1100	-35.4	-38.1 ±0.9	-3.1±7	7.4

Reaction: (A) $S_2Cl_2(l) = S_2Cl_2(g)$ (B) $S_2(g) + Cl_2(g) = S_2Cl_2(g)$.

[a]Points below 298.15 K not analyzed; 2 points rejected due to failure of a statistical test.

[b]Two points rejected due to failure of a statistical test.

[c]Three points rejected.

We adopt $\Delta_f H°(S_2Cl_2, g, 298.15\ K) = -4.0$ kcal mol^{-1} which is the rounded mean value determined from the four 3rd law enthalpies of vaporization. We estimate the uncertainty in the $\Delta_f H°$ value as ±1.0 kcal mol^{-1} which includes contributions from the uncertainties in the values of $\Delta_f H°(298.15\ K)$ and $S°(298.15\ K)$ for the liquid (5). $\Delta_f H°(0\ K)$ is -3.6 kcal mol^{-1} and the enthalpy of atomization is 192.1±1.0 kcal mol^{-1}.

Bodewig and Plambeck (6) determined $\Delta_r G = -12.4$ kcal mol^{-1} for $2\ S(\ell) + 2\ Cl^- = S_2Cl_2(g) + 2\ e^-$ in fused LiCl-KCL eutectic at 693 K. This datum has been analyzed by Mills (7) who reported $\Delta_f H°(298.15\ K)$ value of -5.8±2 kcal mol^{-1}. Our selected $\Delta_f H°$ value is some 0.4 kcal mol^{-1} less negative than that recommended by NBS (8) and is only 0.1 kcal mol^{-1} less negative than the value adopted by Mills (7).

Heat Capacity and Entropy

The heat capacity and entropy values from 298.15 K to 1500 K are those calculated by Frankiss and Harrison (9) who used gas-phase infrared (ν_1 = 546 cm^{-1}, 10) and Raman (9) frequencies and the most recent structural data determined in an electron diffraction study by Beagley et al (11). Contributions to the thermal functions for internal rotation were determined by integration of the potential function from $\phi = 0°$ to 2π. Terms in the potential function were established from the torsional vibration (ν_4 = 92 cm^{-1}) and the dihedral angle (84.8°, 11) of the two rotamers. Thermal functions are calculated below 298.15 K by treating the torsion as a harmonic oscillator and including its contribution in the vibrational partition function. *Justification for* this treatment lies in the fact that values of the ratio V_o/RT become extremely large (>20) at these lower temperatures. We add R*ln* 2 to the calculated entropies below 298.15 K to account for the optical activity of the skew rotamer. The absorption spectra (12) reported for S_2Cl_2 vapor indicate no low-lying electronic states which would contribute to the thermal functions below 1500 K. The principal moments of inertia are: $I_A = 15.2331 \times 10^{-39}$, $I_B = 60.6645 \times 10^{-39}$, and $I_C = 68.8282 \times 10^{-39}$ g cm^2.

Thermodynamic functions previously published for S_2Cl_2 have been reviewed by Frankiss and Harrison (9) who concluded that all previous calculations had treated incorrectly the internal rotation of the SCl top. Noble and Mei (14) have discussed the vibrational spectral data on S_2Cl_2 published prior to 1974.

Enthalpy of Formation

The adopted $\Delta_f H°(SiCl_2, g, 298.15\ K) = -40.3\ kcal\ mol^{-1}$ is the mean value derived from four studies (2, 3, 7, 8). JANAF analyses of all the equilibrium data are summarized below. The $\Delta_f H°(298.15\ K)$ values are calculated from the third law $\Delta_r H°(298.15\ K)$ values using auxiliary JANAF data (1). Four sets of data (2, 3, 7, 8) yield average values of $\Delta_f H°$ (from third law) which agree within 0.4 kcal mol^{-1} and values of $\Delta_r S°$(second law) which are in reasonable agreement with the JANAF functions. Two of these equilibrium studies used flow techniques, one used mass spectrometry, while the fourth used a static technique. The adopted $\Delta_f H°(298.15\ K)$ value corresponds to $\Delta_{at} H°(0\ K) = 204.2\ kcal\ mol^{-1}$ and an average bond energy of 102.1 kcal mol^{-1}. This latter value compares with 94.7 kcal mol^{-1} for $SiCl_4(g)$, implying that the average bond energy in $SiCl_2(g)$ is 7% larger.

Two other flow studies (4, 5) yield large entropy errors, suggesting that there are temperature-dependent errors in $K_p°$. The reported equilibrium constants are reasonable at the lower temperatures but deviate progressively at the higher temperatures. In contrast, the static study of Ishino (6) gave $K_p°$ values which differ by a factor of five from the adopted ones. These data yield a consistent entropy but $\Delta_r H°$ (third law) is lower by 5 kcal mol^{-1}.

Heat Capacity and Entropy

Maass, et al. (9) observed the infrared spectra of $SiCl_2$ in argon, neon, and nitrogen matrices. They observed and assigned all three fundamental frequencies. The bond angle was calculated to be 105±3° from the isotopic splitting. The bond length is assumed to be the same as in SiH_2Cl_2 (1). The earlier work of Milligan and Jacox (10) is consistent with these results. The principal moments of inertia are: $I_A = 5.1016 \times 10^{-39}$, $I_B = 30.5397 \times 10^{-39}$, $I_C = 35.6413 \times 10^{-39}\ g\ cm^2$.

The ground state is assumed to be $^1A_1$ as suggested by Huckel-molecular-orbital calculation (12). Singlet excited states (11, 13) are included near 28000 and 30000 cm^{-1}, but the values are placed in brackets to emphasize the uncertainty in the analysis. Also tentatively adopted is the suggestion by Hastie et al. (13) that the continuous spectrum near 23000 cm^{-1} is due to a triplet excited state.

PREVIOUS: December 1977 (1 atm) CURRENT: December 1977 (1 bar)

$S°(298.15\ K) = 114.809 \pm 0.17\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 1000 \pm 10\ K$
$T_{fus} = 1147 \pm 1\ K$

$\Delta_f H°(0\ K) = -829.34 \pm 2.5\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -828.85 \pm 2.5\ kJ\ mol^{-1}$
$\Delta_{trs} H° = [6.008 \pm 1.3]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 16.221 \pm 0.63\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is from (1) and was selected by Parker in a manner analogous to that described (2) for $\Delta_f H°(BaCl_2, cr)$. The adopted value is essentially that derived by Ehrlich et al (3) from their measurements of $\Delta_{sol} H°$ of Sr(cr) and $SrCl_2$(cr) in HCl(aq, 550 H_2O). Earlier solution data for Sr (4) and $SrCl_2$ (5) are in good agreement.

Parker (2) rejected $\Delta_f H° = -210\ kcal\ mol^{-1}$ obtained by Siemonsen (6) from direct chlorination and $\Delta_f H° = -201.0\ kcal\ mol^{-1}$ which would result from SrO(cr) based on Mah's direction combustion (7). Parker noted that these more negative values are inconsistent with data for $SrCl_2$(cr, aq) and related compounds. They are also less consistent with equilibrium data discussed on the tables for $SrCl_2$(ℓ, g). Impurity effects are of concern in all these studies involving Sr(cr), but the evidence favors the solution calorimetry.

Heat Capacity and Entropy

$C_p°$ is based on adiabatic calorimetry (7.4-300 K) of Smith et al. (8) with omission of the point at 11.22 K which appears to be about 30% low. S° is calculated from $C_p°$ using $S°(7\ K) = 0.012\ cal\ K^{-1}\ mol^{-1}$. $C_p°$ above 300 K is from constrained fitting of enthalpy data (418-936 K for α-phase and 1034-1134 K for β-phase) from Dworkin and Bredig (9).

The transition near 1000 K is gradual and may be second order rather than first order as we have treated it. Gradual transitions also are observed for BaF_2, SrF_2 and perhaps CaF_2, all of which have α-phases of the fluorite structure. Reasonable $C_p°$ curves are obtained by omitting from the curve fits those enthalpy data from about 50 below to 30 above T_{trs}. The resulting Gibbs-energy functions agree well with those obtained (9) by second-order analysis.

Deviations of the fitted data (9) from the adopted functions for α-phase are -0.5 to +0.3% except for +2.0% at 417.6 K. Data of Efremova and Matizen (10) deviate by +0.6 to +2.2% (805-959 K), while the equation of Janz et al. (11) agrees almost exactly near 850 K but deviates by -4.8% at 600 K. The β-phase deviations are -0.4 to +0.3% (9), 0.0 to -1.0% (10, 1047-1142 K) and -2 to 0% (11, 1050-1147 K).

Transition Data

T_{trs} = 1000 K is arbitrarily selected as the peak of the gradual transition. Reported values include 1003 (9), 1002 (11) and 990 K (10). $\Delta_{trs} H°$ is calculated as the difference in the enthalpy curve fits (cf. above) at T_{trs}. $\Delta_{trs} H°$ is assigned an uncertainty of 0.3 kcal mol^{-1} as a first-order transition, but the result is placed in brackets to emphasize that the transition may be a second order. Reported values of $\Delta_{trs} H°$ include 1.65 (9) and 0.65 (11) kcal mol^{-1}.

Fusion Data

See the liquid table for details.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: CURRENT: December 1972

$S°(298.15\ K) = [135.820]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1147 \pm 1\ K$

$\Delta_f H°(298.15\ K) = [-805.352]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 16.221 \pm 0.63\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of the crystal by addition of $\Delta_{fus} H°$ and the difference in enthalpy, H°(1147 K)-H°(298.15 K), between the crystal and liquid. An independent value of $\Delta_f H°$ for liquid (and crystal) may be derived from equilibrium data (1) for $Ca(\ell) + SrCl_2(\ell) \rightarrow Sr(\ell) + CaCl_2(\ell)$ at 1273 K. Our third-law analysis yields $\Delta_r H°(298.15\ K) = 6.5 \pm 1.3$ kcal mol^{-1} or $\Delta_f H°(\ell) = -191.5 \pm 1.5$ kcal mol^{-1} and $\Delta_f H°(cr) = -197.2 \pm 1.5$ kcal mol^{-1}. This confirms the adopted values as opposed to the more negative values (cf. $SrCl_2$, cr).

Heat Capacity and Entropy

The constant $C_p°$ of 25.0 cal K^{-1} mol^{-1} is a compromise chosen by comparison with $BaCl_2$ and $CaCl_2$. Our fits of the enthalpy data yield 26.8 (2) and 23.5 (3) cal K^{-1} mol^{-1}; the adopted value is roughly their mean. The value 26.7 cal K^{-1} mol^{-1} was also reported (4). Deviations from our adopted functions are ±0.3% (2, 1154-1204 K), +1.1 to -1.7% (3, 1152-1797 K) and -1.1 to -0.2% (4, equation, 1148-1287 K). $C_p°$ is taken equal to that of the crystal from 298.15 to 800 K, the assumed glass transition. S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} is selected from 1146 (2), 1147±2 (3) and 1148 K (4) reported in the enthalpy studies. $\Delta_{fus} H°$ is obtained from the difference in the adopted enthalpy fits for liquid and β-phases. Published values include 3.85 (2, 3), 3.88 (2), 3.65±0.17 (4) and 3.73 kcal mol^{-1} (5), the last value obtained by dynamic differential calorimetry.

Vaporization Data

T_{vap} is calculated as the temperature at which $\Delta_r G° = 0$ for $SrCl_2(\ell) \rightarrow SrCl_2(g)$. $\Delta_{vap} H°$ is calculated as the corresponding $\Delta_r H°$.

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from $\Delta_f H°(cr)$ by addition of $\Delta_{sub}H° = 85.0 \pm 1.5$ kcal mol^{-1} derived by third law analysis of the vapor-pressure equation of Hildenbrand et al. (1, 2). The equation (1) summarized five torsion-effusion runs (102 total points) and is reasonably consistent with three boiling pressures in the mmHg range measured by Novikov (3). Effusion studies (4-7) yield lower values of $\Delta_{sub}H°$, but that of Loehman et al. (6) is consistent with the adopted value. Langmuir data (6) suggest that the sublimation coefficient is 0.3±0.2. Equilibria derived from flame studies (8, 9) and mass-spectrometric effusion (10) confirm the adopted $\Delta_f H°$ via independent paths (cf. below). Mass spectra (11) at 1220 K showed that the saturated vapor consists predominantly of $SrCl_2$ with considerably less than 1% of dimer.

[b] Pressures obtained from an equation.
[c] Assuming a sublimation coefficient of 1.0; agreement with (1) requires $\alpha = 0.5$.
[d] $\Delta_r H°$ for $Sr(g) + 2\ HCl(g) = SrCl_2(g) + 2\ H(g)$. [e] $\Delta_r H°$ for $Sr(g) + CaCl_2(g) = SrCl_2(g) + Ca(g)$.

Heat Capacity and Entropy

Vibrations ν_2 and ν_3 are the values quoted by Hildenbrand (10) and derived from IR spectra of molecules in matrix isolation (12). The bending mode was observed (13). Hastie et al. (14) failed to observe ν_2 but estimated a higher value of 60±15 cm^{-1}. Agreement is better for ν_1 = 269 (10, 13) or 274 cm^{-1} (14) and for ν_3 = 300±7 (15, gas), 300 (10, 13) or 307 cm^{-1} (14). We adopt a rounded value of 270 cm^{-1} for ν_1.

Bond length is from gas-phase electron diffraction (16) which also gave the bond angle 180° ± 30°. Later studies (17) of electric deflection of molecular beams revealed a permanent electric dipole moment, leading to the conclusion that $SrCl_2$ is bent. The matrix spectra (10, 12) were first interpreted to give an angle of 155° but reanalysis (13) gave the angle 112°, calculated from the three observed fundamentals. An angle of 130° ± 8° was derived by Hastie et al. (14) from the Cl-isotope splitting of ν_3. We adopt an intermediate value of 120° ± 20°. S° would change by +0.1 cal K^{-1} mol^{-1} for 112° and -1.3 cal K^{-1} mol^{-1} for 155°. The singlet ground state is taken by analogy with $BaCl_2(g)$. Principal moments of inertia are $I_A = 11.5986 \times 10^{-39}$, $I_B = 62.9539 \times 10^{-39}$, and $I_C = 74.5525 \times 10^{-39}\ g\ cm^2$.

$S°(298.15\ K) = 87.345 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -514.76 \pm 16.7\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -515.47 \pm 16.7\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of $TiCl_2$(cr) has been measured calorimetrically. The chosen value of $\Delta_f H°(298.15\ K)$ is the average of two such determinations. Values of $\Delta_f H°(298.15\ K)$ are also calculated from the heats of reaction for the processes (A) $2TiCl_3(cr) = TiCl_2(cr) + TiCl_4(g)$, (B) $3TiCl_2(cr) = 2TiCl_3(g) + Ti(cr)$, and (C) $2TiCl_2(cr) = TiCl_4(g) + Ti(cr)$. These enthalpies of reaction are combined with auxiliary JANAF values for the heats of formation of $TiCl_3$(cr), $TiCl_4$(g), $TiCl_3$(cr) and Ti(cr). The following table summarizes the data used to calculate $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

The heat capacity fo $TiCl_2$(cr) has been measured by Kim and Stout (8) over the range 6 to 300 K. They calculated the adopted value of $S°(298.15\ K)$ from their measurements based on $S°(6\ K) = 0.017\ cal\ K^{-1}\ mol^{-1}$. The heat capacity above 300 K is estimated by graphical extrapolation. The large uncertainty on $S°(298.15\ K)$ is due to the possibiility of sizeable electronic contributions to the heat capacity below 6 K which would account for the rather low value of $S°(298.15\ K)$ reported by Kim and Stout (8).

Sublimation Data

The enthalpy of sublimation is calculated from the enthalpies of formation of $TiCl_2$(cr) and $TiCl_2$(g). The temperature of sublimation is taken as the point at which $\Delta_r G° = 0$ for the process $TiCl_2(cr) = TiCl_2(g)$. These values are hypothetical since $TiCl_2$would be decomposed to $TiCl_3$(g) and $TiCl_4$(g) below this temperature.

Bond Angle: Cl-Ti-Cl = [180]°
Rotational Constant: B_0 = [0.044943] cm^{-1}

Enthalpy of Formation

Gross and Levi (1) have measured the equilibrium $2TiCl_3(g) + Ti(cr) + 3TiCl_2(g)$ at 1723 K and obtain $\Delta_r G°(1723) = 21.7$ kcal mol^{-1} from four measurements. This yields $\Delta_f H°(TiCl_2, g, 298.15\ K) = -56.7 \pm 3$ kcal mol^{-1}. They discuss the measurements of Farber and Darnell (2), on the vapor pressure of $TiCl_2(cr)$, and show that the results are probably in error due to disproportionation of $TiCl_3(g)$ on condensation. In the work of Skinner and Ruehrwein (3) on the reaction $2NaCl(g) + Ti(cr) = 2Na(g) + TiCl_2(g)$, Gross and Levi indicate that the basic assumption, of conversion to $TiCl_2$ only, is erroneous. In the 3rd law analysis of both these data sets significant drifts are obtained which tends to confirm the above arguments.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2(cr)$ reported by Benzinger and Rundle (4). The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to correspond to the inverted states of $NiCl_2(g)$ (5). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (6, 7, 8, 9).

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

TUNGSTEN CHLORIDE (WCl_2) CRYSTAL M_r = 254.756

$S°(298.15\ K) = [130.54]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -257.32 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WCl_2, cr, 298.15\ K) = -61.5 \pm 3\ kcal\ mol^{-1}$, is derived from the heat of combustion, $\Delta_c H° = -140 \pm 3\ kcal\ mol^{-1}$ for $WCl_2(cr) + 3/2\ O_2(g) + WO_3(cr) + Cl_2(g)$, reported by Shchukarev et al. (1). The value of $\Delta_c H°$ was determined calorimetrically, but no further information about the combustion process was given in the paper.

Heat Capacity and Entropy

$C_p°(298.15\ K) = 6.2\ cal\ K^{-1}\ g\text{-}atom^{-1}$ and $C_p°(900\ K) = 7.25\ cal\ K^{-1}\ g\text{-}atom^{-1}$ are estimated using the method described by Kubaschewski and Evans (2). Between 298 and 900, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy, $S°(298.15\ K) = 31.2\ cal\ K^{-1}\ mol^{-1}$, is estimated by the method of Latimer (3). Shchukarev et al. (1), have estimated $\Delta_r S° = -30\ cal\ K^{-1}\ mol^{-1}$ for $W(cr) + Cl_2(g) = WCl_2(cr)$ which leads to $S°(WCl_2, cr, 298.15\ K) = 31.1\ cal\ K^{-1}\ mol^{-1}$, using JANAF auxiliary data.

Decomposition Data

The decomposition temperature, T_{dcm} = 862 K, is obtained by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by Shchukarev et al. (4). Decomposition pressure data for Cl:W ratios less than two suggest that the decomposition reaction is not simple.

Bond Distance: W-Cl = [2.26] Å
Bond Angle: Cl-W-Cl = [180]°
Rotational Constant: B_o = [0.046548] cm^{-1}

Enthalpy of Formation

The value of $\Delta_f H°(WCl_2, g, 298.15\ K) = -3 \pm 25$ kcal mol^{-1} is calculated from the heat of formation of the crystal plus the heat of sublimation, $\Delta_{sub} H°(298.15\ K) = 58.5 \pm 25$ kcal mol^{-1}. The latter is estimated from the heats of sublimation of $TiCl_2$, $CrCl_2$, $MnCl_2$, $FeCl_2$, $CoCl_2$, $NiCl_2$ given by Brewer et al. (1). The uncertainty covers the difference between the heats of sublimation among the above compounds and also the possible error in transference from the first row transition metal dichlorides to tungsten dichloride.

Heat Capacity and Entropy

The molecular configuration of $WCl_2(g)$ is assumed to be linear. The bond distance is estimated to be the same as that in $WCl_6(g)$. The ground state configuration ($^5\Sigma$), the low lying electronic levels and their quantum weights are assumed to be the same as those for $CrCl_2(g)$, observed by DeKock and Gruen (3).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant, K_1, is estimated to be the same as that of $HgCl_2(g)$, 2.7 millidyne/Å. The bending force constant is assumed to be one hundredth of the stretching force constant.

PREVIOUS: December 1966 (1 atm) CURRENT: December 1966 (1 bar)

ZIRCONIUM CHLORIDE ($ZrCl_2$) CRYSTAL M_r = 162.126

$S°(298.15\ K) = [110.039 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [1000]\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-430.95 \pm 41.8]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [26.778 \pm 12.6]\ kJ\ mol^{-1}$

Enthalpy of Formation

The value of $\Delta_f H°(ZrCl_2, cr, 298.15\ K) = -103.0\ kcal\ mol^{-1}$ is calculated from the estimated $\Delta_{sub} H°(298.15\ K) = 58.5\ kcal\ mol^{-1}$ for $ZrCl_2(cr) + ZrCl_2(g)$, using $\Delta_f H°(ZrCl_2, g, 298.15\ K) = -44.5\ kcal\ mol^{-1}$ (1). The estimated $\Delta_{sub} H°(298.15\ K)$ is obtained as an average of the heats of sublimation at 298.15 K for $TiCl_2$, VCl_2, $CrCl_2$, $MnCl_2$, $FeCl_2$, $CoCl_2$, $NiCl_2$ given by Brewer, et al (2).

Heat Capacity and Entropy

The heat capacities of $ZrCl_2(cr)$ are estimated based on the assumption that $C°_p(ZrCl_2, cr) = 1/2[C°_p(ZrCl_4, cr) + C°_p(Zr, cr)]$. The entropy, $S°(298.15\ K)$, is also estimated in a manner similar to that of the heat capacity.

Fusion Data

The melting point was estimated to be 1000 K by Brewer (3) and the heat of melting was also estimated by Glassner (4).

PREVIOUS: June 1962 CURRENT: December 1969

$S°(298.15\ K)$ = [122.493] J K^{-1} mol^{-1}

T_{fus} = [1000] K

$\Delta_f H°(298.15\ K)$ = [-411.594] kJ mol^{-1}

$\Delta_{fus} H°$ = [26.778 ± 12.6] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(ZrCl_2, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(ZrCl_2, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1000\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7.25 cal K^{-1} g-atom^{-1}. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point was estimated to be 1000 K by Brewer (1), and the heat of melting was also estimated by Glassner (2).

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change approaches zero for the process $ZrCl_2(\ell) \rightarrow ZrCl_2(g)$. The difference between $\Delta_f H°$ for $ZrCl_2(\ell)$ and $ZrCl_2(g)$ at T_{vap} is $\Delta_{vap} H°$.

Enthalpy of formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl, $ZrCl_2$, $ZrCl_3$ and $ZrCl_4$. Ion intensities were measured 2.5 cal K^{-1} mol^{-1} above the ionization threshold. Using the reported equilibrium constants for the reaction $ZrCl_4(g) + ZrCl_2(g) \rightarrow 2\ ZrCl_3(g)$ in the temperature range 1673-2110 K, second and third law analyses give the heat of reaction at 298 K as -15.8 and +1.7 kcal mol^{-1}, respectively. The third law drift is 8.9±3.7 cal K^{-1} mol^{-1}. Based on the third law heat of reaction and $\Delta_f H°(ZrCl_4, g, 298.15\ K) = -207.77$ kcal mol^{-1} (2) and $\Delta_f H°(ZrCl_3, g, 298.15\ K) = -125.3$ kcal mol^{-1} (2), we obtain $\Delta_f H°(ZrCl_2, g, 298.15\ K) = -44.5$ kcal mol^{-1} (-186.188±20.9 kJ mol^{-1}) which is adopted in the tabulation.

Farber et al. (3) also studied mass spectrometrically the reaction (a) $Zr(cr) + ZrCl_4(g) \rightarrow 2\ ZrCl_2(g)$ and the reaction (b) $Zr(cr) + 2\ Cl(g) \rightarrow ZrCl_2(g)$. They reported second law heats of reaction as $\Delta_r H°(298.15\ K) = 28.8 \pm 1.8$ kcal mol^{-1} for reaction (a); and -141.1±2.2 kcal mol^{-1} for reaction (b). Third law analysis of the equilibrium constants which were calculated from their ion intensities of run 3 (the only available values) gives $\Delta_f H°(ZrCl_2, g, 298.15\ K) = -43.4$ kcal mol^{-1}. See JANAF $ZrCl_3(g)$ table (2) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that other transition metal dichlorides are linear (4, 5, 6, 7, 8, 9) even though some fluorides are bent (10). The bond distance is assumed to be the same as that of $ZrCl_4(g)$. The electronic levels and quantum weights are estimated to be the same as those of $TiCl_2(g)$ (2).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 2.5 millidyne/Å and the bending force constant 0.05 millidyne/Å.

Enthalpy of Formation

Schafer and Krehl (1) studied the reaction of chlorine with $CoCl_2$ by a transpiration method. They ascribed the enhanced volatility of $CoCl_2$(cr,ℓ) in the presence of Cl_2 to the formation of gaseous $CoCl_3$ according to the reaction $Cl_2(g) + 2\ CoCl_2(g) = 2\ CoCl_3(g)$. Partial pressures for the three species involved in the reaction were reported for the temperature range 918-1073 K. No consideration was given to possible dimerization of either the di- or trichloride. Subsequent measurements by Schafer and Breil (2) have confirmed the increased volatility of $CoCl_2$(ℓ) in the presence of Cl_2. However, the latter study was conducted at only one temperature (1056 K). JANAF data (3) for $CoCl_2$(g) and Co_2Cl_4(g) are used to correct their pressures (1, 2) for dimerization of the dichloride. Our corrected $CoCl_2$ pressures are 5% less than those reported by Schafer and Krehl (1) at 918 K and 11.4% less at 1073 K. We tentatively assume that dimerization of the trichloride is negligible over the temperature range investigated and treat the equilibrium pressures by the second and third law methods. Results of the analysis are: $\Delta_r H°(298.15\ K)$ (2nd Law) = -32.9 and $\Delta_r H°(298.15\ K)$ (3rd Law) = -33.36 ± 2.0 kcal mol^{-1}. The third law drift is -0.5 ± 2.9 cal K^{-1} mol^{-1}. The measurements of Schafer and Breil (2) at 1056 K give $\Delta_r H°(298.15\ K)$ (3rd Law) = -33.31 kcal mol^{-1}. Combining the average value for the third law heats of reaction with $\Delta_f H°(CoCl_2, g, 298.15\ K) = -22.4 \pm 2.0$ kcal mol^{-1} (3), we obtain $\Delta_f H°(CoCl_3, g, 298.15\ K) = -39.1 \pm 2.5$ kcal mol^{-1}. This value is adopted and corresponds to a bond dissociation energy of $D_0{}^0(CoCl_2\text{-}Cl, 298.15\ K) = 45.7$ kcal mol^{-1}. A comparison of this value with that for the monochloride ($D_0{}^0$(Co-Cl, 0 K) = 84.4 kcal mol^{-1}) and dichloride ($D_0{}^0$(CoCl-Cl) = 97.5 kcal mol^{-1}) clearly reveals the instability of the trichloride molecule.

Heat Capacity and Entropy

The structure of CoCl is not known; however, it can be limited to two possibilities. The molecule has either a pyramidal structure of C_{3v} symmetry, or a planar structure of D_{3h} symmetry. By analogy with the geometries for PCl_3 (3), $SiCl_3$ (3) and TiF_3 (3, 4), we adopt the pyramidal structure. The bond length is taken equal to that for CoCl (3). The Cl-Co-Cl bond angle is estimated as 100°. The principal moments of inertia are: $I_A = I_B = 36.1659 \times 10^{-39}$, and $I_C = 60.3628 \times 10^{-39}$ g cm^2.

The vibrational frequencies are estimated by comparison with those for PCl_3 (3), $SiCl_3$ (3) and TiF_3 (4). The ground state quantum weight is taken equal to that for Co^{+3} (5). The electronic levels are estimated from those for Fe^{+2} (5), since few levels have been observed in the spectrum of Co^{+3}. The Fe^{+2} ion is isoelectronic with Co^{+3}. The adopted upper levels and quantum weights contribute 0.65 cal K^{-1} mol^{-1} at 298.15 K and 2.4 cal K^{-1} mol^{-1} at 3000 K to the entropy of $CoCl_3$.

Enthalpy of Formation

The heat of sublimation was determined by second and third law analysis of the following vapor pressure data. Magee (1) measured both vapor pressure by torsion effusion and vapor density in the range 533-644 K and found only trimer present. The second and third law analyses gave $\Delta_{sub}H°(298.15\ K)$ = 37.37±0.04 and 37.24±0.02 kcal mol^{-1} with a drift of -0.25±0.07 cal K^{-1} mol^{-1}. Shelton (2), using Knudsen effusion in the range 547-657 K, obtained $\Delta_{sub}H°(298.15\ K)$ = 40.35±1.4 and 37.42±0.4 kcal mol^{-1} *with a drift of -4.9 cal* K^{-1} mol^{-1}. *Fedorov and Shakhova (3), using transport methods,* obtained vapor pressure over the liquid from 751-1057 K. Using second and third law analysis these gave $\Delta_{sub}H°(298.15\ K)$ = 38.6±1.0 and 39.27±0.5 kcal mol^{-1}.

Brewer and Lofgren (4) obtained equilibrium constants for the reaction 3 Cu(cr) + 3 HCl(g) → Cu_3Cl_3(g) + 1.5 H_2(g). Second and third law analysis of these constants gave $\Delta_r H°(298.15\ K)$ = 3.9±0.6 and 4.39±0.3 kcal mol^{-1} which leads to $\Delta_f H°$ = -61.8±0.5 kcal mol^{-1} (-258.571±2.1 kJ mol^{-1}). This was the value adopted since it is dependent only on HCl(g) and does not involve three times the uncertainty of CuCl(cr) as do the sublimation experiments, which yield values in good agreement but of larger uncertainty.

Heat Capacity and Entropy

The structure of the trimer has been investigated by Wong and Schomaker (5). They conclude that the molecule is planar with D_{3h} symmetry and a Cu-Cl bond length of 2.16 Å. They also state that a very large amplitude of the symetric in-plane bending appears plausible from the diffraction pattern. The infra-red spectrum has been investigated by Klemperer et al. (6). They observed one strong absorption with a maximumm at 350 cm^{-1}; they attribute this to bond stretching motion of type E'. They also suggest that the broad absorption may involve another mode of approximately equal frequency.

In order to estimate the remaining frequencies we assumed that the other infra-red active E' mode would be close to the *observed 350* cm^{-1} *and this was estimated as* 300 cm^{-1}. The in-plane bending is the third E' model and since this has a very large amplitude it was estimated as 60 cm^{-1}. By analogy with other D_{3h} rings the A_2' mode was assumed to be in the same region as the E' stretches and was taken to be 250 cm^{-1}. The $2A_1$' stretches were estimated as 100 and 150 cm^{-1}, while the out of plane A_2" was taken as 200 cm^{-1} and the E" as 80 cm^{-1}. These values gave calculated entropies in excellent agreement with the equilibrium data and thus support the estimates.

The principal moments of inertia are: $I_A = I_B$ = 100.4872 x 10^{-39} g cm^2, I_C = 200.9745 x 10^{-39} g cm^2.

PREVIOUS: December 1960 (1 atm) CURRENT: December 1960 (1 bar)

$S°(298.15\ K) = 142.336\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 577\ K$

$\Delta_f H°(0\ K) = -400.833 \pm 0.84\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -399.405 \pm 0.84\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.095\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy change, $\Delta_r H°(298.15\ K) = -24.49 \pm 0.07\ kcal\ mol^{-1}$, for the reaction $Fe(cr) + 3(HCl \cdot 12.731\ H_2O)(\ell) + 1/2(H_2O_2 \cdot 12.580\ H_2O)(\ell) = FeCl_3(cr) + H_2(g) + 45.483\ H_2O(\ell)$ *was determined by Koehler and Coughlin* (1). This leads to $\Delta_f H°(298.15\ K) = -95.46 \pm 0.20\ kcal\ mol^{-1}$ for $FeCl_3(cr)$, using $\Delta_f H°(298.15\ K) = -38.9 \pm 0.05$ and $-68.32 \pm 0.01\ kcal\ mol^{-1}$ for hydrochloric acid and hydrogen peroxide solution, respectively, obtained from Rossini et al. (2). From $\Delta_r H°(298.15\ K) = -38.0 \pm 0.2\ kcal\ mol^{-1}$ for the reaction $FeCl_3(cr) = Fe^{+++}(aq)$ reported by Li and Gregory (3), the value of $\Delta_f H°(FeCl_3, cr, 298.15\ K)$ was calculated as $-93.26 \pm 0.2\ kcal\ mol^{-1}$. The former $\Delta_f H°(298.15\ K)$ value is adopted.

The equilibrium pressures of the reaction $2\ FeCl_2(cr) + Cl_2(g) = 2FeCl_3(cr)$, in the temperature range of 435.7-482.2 K, were measured by Schafer and Oehler (4). Using the reported partial pressures for $Cl_2(g)$, the enthalpy change $\Delta_r H°(298.15\ K)$ of the reaction was evaluated as -27.49 ± 0.44 and $-27.21\ kcal\ mol^{-1}$ by the 2nd and 3rd law methods, respectively. Based on the 3rd law value for $\Delta_r H°(298.15\ K)$, the value of $\Delta_f H°(FeCl_3, cr, 298.15\ K)$ was derived to be $-95.36 \pm 0.12\ kcal\ mol^{-1}$ which is in good agreement with the adopted value.

Heat Capacity and Entropy

The low temperature (51-298.16 K) heat capacities and high temperature (339.6-560.9 K) heat content of $FeCl_3(cr)$ were determined by Todd and Coughlin (5). The low temperature $C_p°$ and the derived high temperature $C_p°$ were plotted. The two $C_p°$ curves were joined smoothly at 298.15 K). The $C_p°$ values above 560.9 K were obtained by graphical extrapolation. The value of $S°(298.15\ K)$ was derived from the low temperature data reported by Todd and Coughlin (5), using $S°(51\ K) = 6.29\ cal\ K^{-1}\ mol^{-1}$. The value of $S°(51\ K)$ was selected to make the second and third law values of $\Delta_r H°$, derived from the equilibrium data reported by Schafer and Oehler, (4), in good agreement. The difference in $S°(51\ K)$ between the selected value, 6.29, and the reported value, $4.50\ cal\ K^{-1}\ mol^{-1}$, by Todd and Coughlin (5), is assumed to be the magnetic entropy remaining at 51 K which was unaccounted for in the report.

Fusion Data

T_{fus} and $\Delta_{fus} H°$ were obtained from Todd and Coughlin (5).

Sublimation Data

The difference between $\Delta_f H°(298.15\ K)$ for $Fe_2Cl_6(g)$ and $2FeCl_3(cr)$ is the enthalpy of sublimation at 298.15 K. The former is obtained by the 2nd and 3rd law analyses of related equilibrium data. See $Fe_2Cl_6(g)$ table for details.

IRON CHLORIDE ($FeCl_3$) LIQUID M_r = 162.206

$S°(298.15\ K) = [200.657] J\ K^{-1}\ mol^{-1}$

$T_{fus} = 577\ K$

$\Delta_f H°(298.15\ K) = [-362.815]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 43.095\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(FeCl_3, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(FeCl_3, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(577\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity for $FeCl_3(\ell)$ was taken from Todd and Coughlin (1) and assumed as constant between 298.15 and 1500 K. $S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} and $\Delta_{fus} H°$ were reported by Todd and Coughlin (1).

Vaporization Data

The boiling point (T_{vap}) is determined as the temperature at which the Gibbs energy change ($\Delta_r G°$) of the reaction $2FeCl_3(\ell) = Fe_2Cl_6(g)$ is zero. The corresponding enthalpy change at T_{vap} is the enthalpy vaporization.

[160](1)
[310](2)
[130](2)

Ground State Quantum Weight: [6] σ = [6]
Point Group: D_{3h}
Bond Distance: Fe-Cl = [2.17] Å
Bond Angle: Cl-Fe-Cl = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [1.43810 \times 10^{-112}] g^3\ cm^6$

Enthalpy of Formation

The equilibrium pressures for the reaction $Fe_2Cl_6(g) = 2FeCl_3(g)$ were determined by Kangro and Bernstorff (1) and Schafer (2), respectively. Using their vapor pressure data the corresponding values of $\Delta_r H°(298.15\ K)$ for that reaction were evaluated by both the 2nd and 3rd law methods. Based on the 3rd law values for $\Delta_r H°(298.15\ K)$, the heats of formation $\Delta_f H°(298.15\ K)$ for $FeCl_3(g)$ were derived. The results obtained are presented as follows.

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Kangro and Bernstorff (1)	760.2-1014.2	34.99±0.44	35.73	-60.34±0.30
Schafer (2)	673.2-1073.2	34.81±0.02	34.93	-60.74±0.20

The adopted value of $\Delta_f H°(FeCl_3, g, 298.15\ K)$ is -60.5 ± 1.2 kcal mol^{-1}.

Heat Capacity and Entropy

The molecular structure was assumed to be the same as that of $AlCl_3(g)$ due to the similarities in structure between $Fe_2Cl_6(g)$ and $Al_2Cl_6(g)$. The Fe-Cl bond distance was estimated by comparison with those for $Fe_2Cl_6(g)$ reported by Zasorin et al. (3) and Hassel and Viervoll (4). Both the ground state quantum weight and vibrational frequencies were estimated so that the second and third law values of $\Delta_r H°(298.15\ K)$, derived from the vapor pressure data, for the reaction $Fe_2Cl_6(g) = 2FeCl_3(g)$ are in reasonable agreement. The principal moments of inertia are: $I_A = I_B = 41.5834 \times 10^{-39}$ and $I_C = 83.1667 \times 10^{-39}$ g cm^2.

254(1)	176(2)

Ground State Quantum Weight: [1] $\sigma = 3$

Point Group: C_{3v}

Bond Distances: Si-H = 1.4655 Å Si-Cl = 2.0118 Å

Bond Angles: H-Si-Cl = 108.32° Cl-Si-Cl = 110.60°

Product of the Moments of Inertia: $I_A I_B I_C = 7.59150 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from that of $SiCl_4(g)$ (1) using the difference $\Delta(\Delta_f H°) = 39.8$ kcal mol^{-1} taken from the analysis of Hunt and Sirtl (2). The authors derived $\Delta_f H°(SiHCl_3, g, 298.15\ K) = -116.9 \pm 0.7$ kcal mol^{-1} from six previously reported equilibrium studies. These were at temperatures (773-1200 K) and compositions where the dominant equilibrium was $SiHCl_3 + HCl = SiCl_4 + H_2$. *Selected data (2) were either close to or extrapolated to infinite residence time.* Equilibria were reduced to $\Delta_f H°(298.15\ K)$ using auxiliary data (2) which are similar to JANAF values (1), except for $\Delta_f H°(SiCl_4, g, 298.15\ K)$. Since this is now 1.7 kcal mol^{-1} more negative, we change $\Delta_f H°(SiHCl_3)$ accordingly. Our adopted value is 1.8 kcal mol^{-1} more negative than that estimated by linear interpolation between $SiCl_4(g)$ and $SiH_4(g)$. (1)

We dismiss two calorimetric values due to probable bias. These include $\Delta_f H°(\ell) = -112$ kcal mol^{-1} from oxygen-bomb calorimetry (3) and $\Delta_f H°(g) = -117.4 \pm 1.7$ kcal mol^{-1} from solution calorimetry (4) in dilute aqueous NaOH. Revised auxiliary data (1, 5) change these values to $\Delta_f H°(g) = -115$ (3) and -124 kcal mol^{-1}. Wagman et al. (5) adopted -122.6 kcal mol^{-1}, presumably based on Wolf (4). The combustion result is suspect because the chemical reaction was determined only qualitatively and included corrosion reactions of the bomb (3). In our approximate revision of the solution result, we eliminate $Na_2SiO_3(cr)$ by taking the difference between the overall reactions (4) for $SiCl_4(\ell)$ and $SiHCl_3(g)$. This yields the difference $\Delta(\Delta_f H°) = \Delta_f H°(SiHCl_3, g) - \Delta_f H°(SiCl_4, g) = 34.6$ compared to 39.8 kcal mol^{-1} (2). The solution result is suspect due to the possibility that the two hydrolyses did not proceed to equivalent degrees. Solution results (4) for $SiCl_4$, $SiBr_4(\ell)$ and $SiI_4(cr)$ also have a negative bias compared to our adopted values (1).

Heat Capacity and Entropy

The molecular structure is based on microwave data of Mitzlaff et al. (6) for twleve isotopic forms of $SiHCl_3$ and $SiDCl_3$. Structural parameters are substitutional (r_s) values. They are in reasonable agreement with previous data (6) determined by various methods. The principal moments of inertia are $I_A = I_B = 34.3279 \times 10^{-39}$ and $I_C = 64.4220 \times 10^{-39}\ g\ cm^2$.

Vibrational frequencies are those selected by Shimanouchi (7) from gas-phase infrared spectra of Buerger and Ruoff (8). Assignments are based on band contours and isotopic splittings and are consistent with recent liquid-phase Raman spectra (9).

We neglect excited states and assume the electronic ground state to be a singlet. We expect that contributions from excited states should be unimportant, as discussed on the tables for SiH_2Cl_2, SiH_3Cl and SiH_3Br (1).

LITHIUM CHLORIDE $((LiCl)_3)$ IDEAL GAS $M_r = 127.182$

$S°(298.15\ K) = [335.747]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -997.47\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1004.72 \pm 20.9\ kJ\ mol^{-1}$

Vibrational Levels and Degeneracies

ν, cm^{-1}
[650](6)
[220](6)

Point Group: D_{3h} $\sigma = 6$

Bond Distance: Li-Cl = [2.2] Å

Bond Angle: Li-Cl-Li = [120]°

Product of the Moment of Inertia: $I_A I_B I_C = 2.67006 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

The heat of sublimation at 298.15 K was chosen so as to give the correct ratio of monomer, dimer and trimer at 870 K. The value used was 52.6 kcal mol^{-1} which compares very well with the value 53.6 kcal mol^{-1} obtained from a third law analysis of the data of Nesmeyanov and Sazonov (1) in conjunction with the relative concentrations of monomer, dimer, and trimer at 870 K from the work of Miller and Kusch. (2).

Heat Capacity and Entropy

The postulated structure, bond lengths and frequencies were all taken from Hildenbrand et al. (3). The principal moments of inertia are: $I_A = I_B = 51.1090 \times 10^{-39}$ and $I_C = 102.2179 \times 10^{-39}$ g cm^2.

1290(1)	486(1)	337(1)
581(2)	267(2)	193(2)

Point Group: C_{3v} $\sigma = 3$
Bond Distances: P-O = 1.45 ± 0.03 Å P-Cl = 1.99 ± .02 Å
Bond Angle: Cl-P-Cl = 103.6 ± 2°
Product of the Moments of Inertia: $I_A I_B I_C = 1.01841 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

The $\Delta_f H°(298.15\ K)$ for $POCl_3(g)$ was derived from the $\Delta_f H°(298.15\ K)$ of $POCl_3(\ell)$ and the $\Delta_{vap} H°(298.15\ K)$. The $\Delta_f H°(298.15\ K)$ of the $POCl_3(\ell)$ was calculated from the heat of hydrolysis observed by Charnley and Skinner (1) for the reaction:

$$POCl_3(\ell) + (n + 3)\ H_2O(\ell) \rightarrow [H_3PO_4 + 3\ HCl]\ in\ n\ H_2O(\ell)$$

The auxiliary thermochemical data, on the enthalpies of formation of water and aqueous solutions of HCl and of H_3PO_4, were taken from the (2), and were adjusted for consistency with JANAF Tables. The heat of vaporization was measured and corrected to 298.15 K by Ott and Giauque (3).

Heat Capacity and Entropy

The molecular constants are from the microwave spectral data of Williams et al. (4). In order to determine the structure Williams et al. (4) assumed the P-Cl distance equal to 1.99 Å. This was the smallest value allowed (2.02±0.03 Å) by the electron diffraction work of Brockway and Beach (5).

Ott and Giauque (3) have given the moments of inertia obtained from a weighted average of the iotopic species. $I_A \neq I_B$ due to isotopic loss of symmetry. The S°(298.15 K) calculated from calorimetric data by Ott and Giauque (3) was 77.75 cal $K^{-1}\ mol^{-1}$ and the S°(298.15 K), calculated from the spectral data was 77.77 cal $K^{-1}\ mol^{-1}$.

The principal moments of inertia are: $I_A = I_B = 42.0514 \times 10^{-39}$ and $I_C = 57.5920 \times 10^{-39}\ g\ cm^2$.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

PHOSPHORUS CHLORIDE (PCl_3) IDEAL GAS M_r = 137.33276

$S°(298.15\ K) = 311.682 \pm .42\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -285.50 \pm 5.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -288.70 \pm 5.4\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
510 (1)	507 (2)
259 (1)	187 (2)

Ground State Quantum Weight = 1 $\sigma = 3$

Point Group: C_{3v}

Bond Distance: P-Cl = 2.039 ± 0.0014 Å

Bond Angle: Cl-P-Cl = 100.27 ± 0.09°

Product of the Moments of Inertia: $I_A I_B I_C = 6.05196 \times 10^{-113}\ g^3\ cm^6$

Enthalpy of Formation

Neale and Williams (1) measured the heat of hydrolysis of liquid phosphorus trichloride and reported a $\Delta_r H° = -67.5 \pm 0.3$ kcal mol^{-1} for the following reaction:

$$PCl_3(\ell) + (X_2 + 3)\ H_2O + H_3PO_3(aq) + 3\ HCl(aq)$$

with X_2 in range 4500 to 7500. Combining this result with enthalpy of formation data for aqueous H_3PO_3, -229.4 kcal mol^{-1} (2, 5, 16), H_2O (2) and aqueous HCl (2), we derive $\Delta_f H°(PCl_3, \ell, 0\ K) = -76.7$ kcal mol^{-1}. Charnley and Skinner (3) made an independent investigation of the hydrolysis of liquid phosphorus trichloride and obtained enthalpy data in very good agreement with Neale and Williams' results. Their results lead to $\Delta_f H°(PCl_3, \ell, 0\ K) = -76.5$ kcal mol^{-1} when combined with heat of formation data (2, 5, 16).

Neale and Williams (4) also investigated the hydrolysis of liquid phosphorus trichloride in aqueous bromine solution with the formation of phosphoric acid rather than phosphorus acid which results when hydrolysis occurs in water. They reported a $\Delta_r H° = -137.9$ kcal mol^{-1} for the following reaction:

$$PCl_3(\ell) + Br_2(aq) + (X_2 + 4)H_2O + H_3PO_4(aq) + 3\ HCl(aq) + 2\ HBr(aq)$$

with X_2 in range 3500 to 6300. Combining this result with the following enthalpy of formation data: $\Delta_f H°(H_3PO_4 \cdot 1\ H_2O) = -306.4 \pm 0.5$ kcal mol^{-1} (5), $\Delta H°(Br, aq) = -0.2$ $kcal^{-1}$ mol (6), HCl(aq) and HBr(aq) (2), along with dilution data for $H_3PO_4(aq)$ (2), we derive $\Delta_f H°(PCl_3, \ell, 298.15\ K) = -77.0$ kcal mol^{-1}.

The enthalpy of formation from white phosphorus of gaseous PCl_3, $\Delta_f H°(PCl_3, g, 298.15\ K) = -69.0 \pm 1.1$ kcal mol^{-1}, is calculated from $\Delta_f H°(PCl_3, \ell, 298.15\ K) = -76.7 \pm 1.0$ kcal mol^{-1}, an average value of the three results given above, and the enthalpy of vaporization of PCl_3. $\Delta_{vap} H°(298.15\ K) = 7.7 \pm 0.1$ kcal mol^{-1} is determined from a 2nd law analysis of the combined vapor pressure data of Nisel'son and Seryakov (7) and Regnault (8). The smoothed vapor pressure data of Regnault as reported by Stull (9) were used.

An independent value for the heat of formation can be obtained from the work of Duus and Mykytiuk (17) on the reaction 1.5 $CaF_2 + PCl_3(g) \rightarrow 1.5\ CaCl_2 + PF_3(g)$. The authors reported $\Delta_f H°(630\ K) = -2.97$ kcal mol^{-1}. From a re-examination of their technique we believe that this heat evolution is likely to be too small, perhaps by 100%. The analytical results indicate that the reaction is 99% complete or better; thus, we can use this with JANAF entropies to calculate $\Delta_r H°(298.15\ K) \leq 3.55$ kcal mol^{-1}. Finch et al. (18) have reported $\Delta_f H°(CaF_2, cr, 0\ K) - \Delta_f H°(CaCl_2, cr, 0\ K) = -100.87 \pm 0.02$ kcal mol^{-1}; thus, we obtain $\Delta_f H°(PCl_3, g, 298.15\ K) > -70.1 \pm 2.0$ kcal mol^{-1} from $\Delta_f H°(PF_3, g, 298.15\ K) = -224.9 \pm 0.9$ kcal mol^{-1}. This value is not adopted because of the lack of calorimeter calibration, but it offers an attractive possibility for further study.

Heat Capacity and Entropy

The molecular structure and bond length given above for PCl_3 are from the electron diffraction studies of Hedberg and Iwasahi (11). The adopted values are in good agreement within experimental error with the following structural data reported by Kisliuk and Townes (12) from microwave studies: $r_{P-Cl} = 2.043 \pm 0.003$ Å, the angle Cl-P-Cl = 100°6'±20'. The vibrational frequencies are from the recent infrared and Raman studies of Frankiss and Miller (13) and are in excellent agreement with those of Muller et al. (14) and Davis and Oetjen (15). The principal moments of inertia are: $I_A = I_B = 32.3918 \times 10^{-39}$ and $I_C = 57.6799 \times 10^{-39}$ g cm^2.

Ground State Quantum Weight: 1 $\sigma = 3$
Point Group: C_{3v}
Bond Distances: P-S = 1.85 ± 0.02 Å P-Cl = 2.02 ± 0.01 Å
Bond Angle: Cl-P-Cl = 100.5° ± 1°
Product of the Moments of Inertia: $I_A I_B I_C = 2.06885 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was estimated by Henderson and Scheffee (1). Henderson and Scheffee use white (α) phosphorus as a reference state.

Heat Capacity and Entropy

Ziomek and Piotrowski (2) have chosen the most probable values for the wave numbers from the infrared spectral data of Cilento et al. (3) and the Raman spectral data of Simon and Schulze (4), Thatte (5), Gerding and Westrick (6) and Delwaulle and Francois (7). Ziomek and Piotrowski (2) found their normal coordinate treatments gave the listed wave numbers as fundamentals and lent support for the 247 cm^{-1} band missing from the Raman spectral data. The structure (bond distances and angles) was determined from microwave data by Williams et al. (8). The principal moments of inertia are: $I_A = 56.7997 \times 10^{-39}$, $I_B = I_C = 60.3519 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

The adopted value for the heat of formation of $SiCl_3(g)$ is based on the mass spectrometric study of the silicon subchlorides by Farber and Srivastava (1). Our 2nd and 3rd law analysis of ten data points (1593-1792 K) for the equilibrium $SiCl_4(g) + SiCl_2(g) = 2\ SiCl_3(g)$ yield $\Delta_r H°(298.15\ K)$(2nd law) = 6.4±1.1 kcal mol^{-1} and $\Delta_r H°(298.15\ K)$(3rd law) = 12.0±0.5 kcal mol^{-1} with a drift of 3.3±0.6 cal $K^{-1}\ mol^{-1}$. Using the 3rd law heat of reaction and auxiliary data (2), we calculate and adopt $\Delta_f H°(SiCl_3, g, 298.15\ K) = -93.3 \pm 2$ kcal mol^{-1}. This leads to $\Delta_a H°(0\ K) = 285.5 \pm 2$ kcal mol^{-1} or an average bond energy of 95.2 kcal mol^{-1}; a value which is within 0.5 kcal mol^{-1} of the average bond energy in $SiCl_4(g)$.

Many less definitive studies leading to the heat of formation of $SiCl_3(g)$ are reported in the literature. These studies yield values which are 5-10 kcal mol^{-1} less negative than our adopted value. These works include the relative reaction rates of $SiCl_3$ by Kerr et al. (3), decomposition studies of $SiCl_4$ by adiabatic compression by Vurzel et al. (4), interpretation of electron impact studies on several molecules by Steele et al. (5), examination of infrared emission of a reaction involving $SiCl_3(g)$ by Cadman et al. (6), silane kinetic studies by Walsh and Wells (7), and negative ion studies by Wang et al. (10) and Pabst et al. (11).

Heat Capacity and Entropy

Jacox and Milligan (8) studied the formation of $SiCl_3$ by photolysis of $HSiCl_3$ in matrices of argon, nitrogen and CO. The two stretching fundamentals were assigned from the infrared spectra. Isotopic splittings were found to be consistent with an angle of 72±5° between the threefold axis and each of the Si-Cl bonds. This yields a bond angle of 110.9° which is similar to that of $HSiCl_3$. Non-planarity of $SiCl_3$ is consistent with the electron-spin-resonance studies of Roncin (9).

We adopt the results of Jacox (8) and estimate the bond length and two bending vibrations by analogy with $HSiCl_3$ (2). The ground state quantum weight is taken as two, but excited electronic levels are neglected. Jacox (8) observed unstructured absorptions corresponding to excitation energies of 30000-34500 cm^{-1} and 41000-46000 cm^{-1}. The principal moments of inertia are: $I_A = I_B = 33.7539 \times 10^{-39}$ and $I_C = 64.6554 \times 10^{-39}\ g\ cm^2$.

$S°(298.15\ K) = 139.750 \pm 1.3\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 220.1\ K$

$\Delta_f H°(0\ K) = -724.06 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -721.74 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(298.15\ K)$, of $TiCl_3(cr)$ has been measured by several investigators. The results of these measurements are as follows.

Source	Method	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
Schaffer et al. (1954) (1)	Calorimetric, $TiCl_4 + Hg = TiCl_3 + 1/2\ Hg_2Cl_2$	-171.9, -172.4
Clifton and MacWood (1956) (2)	Solution calorimetric	-172.4
Johnson et al. (1956) (3)	Calorimetric, $TiCl_4(\ell) + HI(g) = TiCl_3(cr) + HCl(g) + 1/2\ I_2$	-172.5
Krieve et al. (1956) (5)	Solution calorimetric	-171.3
Krieve and Mason (1956) (5)	Equilibrium, $TiCl_3(cr) + HCl(g) = TiCl_4(g) + 1/2\ H_2(g)$	-172.9
Altman et al. (1956) (6)	Equilibrium, $Ti(cr) + 3\ TiCl_4(\ell) = 4\ TiCl_3(cr)$	-169.4, -171.0
Head (1960) (7)	Equilibrium, $2\ TiCl_4(2) + H_2(g) = 2\ TiCl_3(cr) + 2\ HCl(g)$	-172.3
	$TiCl_4(\ell) + Hg(\ell) = 1/2\ Hg_2Cl_2(cr) + TiCl_3(cr)$	
	$TiCl_4(\ell) + Ag(cr) = AgCl(cr) + TiCl_3(cr)$	

The chosen value of -172.5±1.0 kcal mol^{-1} is that reported by Johnson et al. (3).

Heat Capacity and Entropy

The heat capacity and entropy of $TiCl_3(cr)$ has been measured over the temperature range 54 to 1000 K by King et al. (8). The value of $S°(298.15\ K)$ is calculated from these data based on $S°(51\ K) = 4.29\ cal\ K^{-1}\ mol^{-1}$.

Transition Data

A second order transition at 220.1 K was observed by King et al. (8). The heat capacity at this temperature is in excess of 146.8 cal $K^{-1}\ mol^{-1}$. King et al. (8) measured the value of $H°(240\ K) - H°(200\ K)$ as 1.213 kcal mol^{-1}.

Sublimation Data

The enthalpy of sublimation is calculated from the enthalpies of formation of $TiCl_3(cr)$ and $TiCl_3(g)$ at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta_r G° = 0$ for the process $TiCl_3(cr) = TiCl_3(g)$.

Enthalpy of Formation

The enthalpy of formation of $TiCl_3(g)$ is calculated from the heats of reaction for the processes, (A) $3TiCl_4(g) + Ti(cr) = 4TiCl_3(g)$, and (B) $TiCl_3(cr) = TiCl_3(g)$, combined with auxiliary JANAF heats of formation for $TiCl_4(g)$, $TiCl_3(cr)$ and Ti(cr). Equilibrium measurements of reaction (A) have been reported by Gross and Levi (1). Vapor pressure measurements for reaction (B) have been reported by Sanderson and MacWood (2) and by Farber and Darnell (3). Second and third law analyses of these data yield the following results.

Source	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ k cal mol^{-1}
Gross and Levi (1)	A	3	1223		31.6±2.0		-128.5
Sanderson and MacWood (2)	B	9*	628-823	42.8±1.1	42.8	-0.1±1.5	-129.3
Farber and Darnell (3)	B	8	636-723	45.3±2.1	45.8	0.8±3.1	-126.2

*One point rejected due to failure of statistical test.

The chosen value of $\Delta_f H°(298.15\ K)$ is -128.9 kcal mol^{-1}. This value is the average of the first two determinations.

Heat Capacity and Entropy

The interatomic distance is estimated from that of the solid, given as 2.46 Å by Natta et al. (4), and from comparisons of bond distances of crystal and gas phase tetrahalides of titanium. The pyramidal bond angle is estimated assuming $TiCl_3(g)$ similar to the group V trihalides. The principal moments of inertia are: $I_A = I_B = 42.8614 \times 10^{-39}$ and $I_C = 73.1025 \times 10^{-39}\ g\ cm^2$. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} (5).

$S°(298.15\ K) = [145.812 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-714.21 \pm 62.8]\ kJ\ mol^{-1}$

Enthalpy of Formation

Turnbull and Watts (1) *determined the equilibrium pressures for the disproportionation of* $ZrCl_3$(cr) in the temperature range from 613 K to 723 K by a modified dew point technique. 2nd and 3rd law analyses of their vapor pressure-temperature equation give the same enthalpy of reaction $\Delta_r H°(298.15\ K) = 30.7$ kcal mol^{-1} for $2ZrCl_3(cr) + ZrCl_2(cr) + ZrCl_4(g)$. The adopted value, $\Delta_f H°(ZrCl_3, cr, 298.15\ K) = -170.7$ kcal mol^{-1}, is calculated from the enthalpy of reaction at 298.15 K, and $\Delta_f H°(ZrCl_4, g, 298.15\ K) = -207.77$ kcal mol^{-1} (2) and $\Delta_f H°(ZrCl_2, cr, 298.15\ K) = -103$ kcal mol^{-1} (3). The assigned uncertainty, ±15 kcal mol^{-1} is mainly due to the uncertainty in the enthalpy of formation of $ZrCl_2$(cr), and also the dew point technique used.

Heat Capacity and Entropy

The heat capacities of $ZrCl_3$(cr) are estimated from the $C_p°$ values of $ZrCl_4$(cr) by deduction of one Cl atom $C_p°$ contributions which are calculated as $1/4[C_p°(ZrCl_4, cr) - C_p°(Zr, cr)]$. The $S°(298.15\ K)$ is calculated as 34.85 cal K^{-1} mol^{-1} based on the assumption that $S°(ZrCl_3, cr, 298.15\ K) = S°(ZrCl_4, cr, 298.15\ K) - 1/4[S°(ZrCl_4, cr, 298.15\ K) - S°(Zr, cr, 298.15\ K)]$.

Sublimation Data

The enthalpy of sublimation is calculated from the difference in the enthalpies of formation of gas and crystal at 298.15 K. The sublimation temperature is taken as the point at which $\Delta_r G = 0$ for $ZrCl_3(cr) = ZrCl_3(g)$.

Enthalpy of Formation

Potter (1) investigated mass spectrometrically the equilibrium CaCl(g) + $ZrCl_4$(g) + $CaCl_2$(g) + $ZrCl_3$(g) in the temperature range 1163-1157 K. Ion intensities were measured 2.5 eV above threshold and they were used in the calculation of equilibrium constants. Using the reported equilibrium constants, the enthalpies of reaction at 298 K are evaluated by the 3rd law and 2nd law methods as -3.69 and -16.67 kcal mol^{-1}, respectively. The 3rd law drift is 9.31±1.25 cal K^{-1} mol^{-1}. Using the 3rd law $\Delta_r H°(298.15\ K)$ = -3.69 kcal mol^{-1}, $\Delta_f H°(ZrCl_4, g, 298.15\ K)$ = -207.77 kcal mol^{-1} (2), $\Delta_f H°(CaCl, g, 298.15\ K)$ = -28.8 kcal mol^{-1} (3) and $\Delta_f H°(CaCl_2, g, 298.15\ K)$ = -115.0 kcal mol^{-1} (4), we obtain $\Delta_f H°(ZrCl_3, g, 298.15\ K)$ = -125.3 kcal mol^{-1}, which is adopted in the tabulation.

Farber et al. (5) also studied mass spectrometrically the reaction Zr(cr) + 3 $ZrCl_4$(g) + 4 $ZrCl_3$(g) in the temperature range from 1579 K to 1729 K. They reported a second law heat of reaction as $\Delta_r H°(298.15\ K)$ = 59.2±1.6 kcal mol^{-1}. Since the attainment of equilibrium was questionable in their studies, the heat of reaction obtained from the third law method is generally more reliable. Using their reported ion intensities of run 3 (temperature range from 1667 K to 1896 K, five points), we have calculated the equilibrium constants $K_1 = (I_{ZrCl_2})^2/(I_{ZrCl_3})(I_{ZrCl})$ for reaction (1) $ZrCl_3$(g) + ZrCl(g) + 2 $ZrCl_2$(g); and $K_2 = (I_{ZrCl_3})^2/(I_{ZrCl_4})(I_{ZrCl_2})$ for reaction (2) $ZrCl_4$(g) + $ZrCl_2$ + 2 $ZrCl_3$(g). Third law analyses of the equilibrium constants give $\Delta_r H°(298.15\ K)$ = -11.0 kcal mol^{-1} for reaction (1) and its drift 4.1±1.7 cal K^{-1} mol^{-1}; and $\Delta_r H°(298.15\ K)$ = 1.4 kcal mol^{-1} for reaction (2) and its drift 11.1±1.2 cal K^{-1} mol^{-1}. Using the 3rd law heats of reaction, and $\Delta_f H°(ZrCl, g, 298.15\ K)$ = 49.1 kcal mol^{-1} (2) and $\Delta_f H°(ZrCl_4, g, 298.15\ K)$ = -207.77 kcal mol^{-1} (2), we obtain $\Delta_f H°(ZrCl_3, g, 298.15\ K)$ = -124.9 kcal mol^{-1} and $\Delta_f H°(ZrCl_2, g, 298.15\ K)$ = -43.4 kcal mol^{-1} which are in good agreement with the values adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be a pyramid similar to the group VA trichlorides. The bond distance is assumed to be the same as that of $ZrCl_4$(g). The principal moments of inertia are: $I_A = I_B$ = 45.9362 x 10^{-39} and I_C = 73.1025 x 10^{-39} g cm^2. The electronic levels are estimated as three times higher than those of $TiCl_3$(g), based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by Moore (6). The quantum weights are assumed to be the same as those of $TiCl_3$(g).

Vibrational frequencies are calculated from the estimated force constants by the valence force method (7). The force constants are estimated from those of PCl_3, $AsCl_3$ and $SbCl_3$ listed by Herzberg (7).

Point Group: $[D_{2h}]$ $\sigma = 4$

Bond Distances: Co-Cl = [2.09] Å Co-Cl'(bridge) = [2.2] Å

Bond Angles: Co-Cl'(bridge)-Co = [90]° Cl'(bridge)-Co-Cl = [135]° Cl'(bridge)-Co-Cl'(bridge) = [90]°

Product of Moments of Inertia: $I_A I_B I_C = [1.34964 \times 10^{-111}]\ g^3\ cm^6$

Enthalpy of Formation

Mass spectrometric studies (1, 2) have indicated the presence of small amounts of dimer in the saturated vapor over $CoCl_2(cr)$. *The existence of the dimeric species was inferred from the ion current intensities observed for* $Co_2Cl_4^+$. This ion is believed to be produced by simple ionization of the dimer molecules. Schoonmaker et al. (1) have combined their mass spectral data with results of effusion vapor pressure measurements to give partial pressures for the monomer and dimer at 817 K. These results are analyzed by the third law method with JANAF free energy functions to give ΔH(dimerization, 298.15 K) = -38.99 kcal mol^{-1} for the process 2 $CoCl_2(g) = Co_2Cl_4(g)$. This result is combined with $\Delta_f H°(CoCl_2, g, 298.15\ K) = -22.4 \pm 2.0$ kcal mol^{-1} (3) to give $\Delta_f H°(Co_2Cl_4, g, 298.15\ K) = -83.8$ kcal mol^{-1} (350.619±29.3 kJ mol^{-1}) which we adopt. The uncertainty assigned to $\Delta_f H°$ is estimated to be ±7.0 kcal mol^{-1} and arises mainly from uncertainties in the values of S°(298.15 K) for dimer and $\Delta_f H°$ for the monomer.

Heat Capacity and Entropy

A bridge-bond structure of D_{2h} symmetry is assigned to Co_2Cl_4. A similar structure has been proposed for Be_2Cl_4(3) and other dimeric transition-metal dihalides (3-5). The Co_2Cl_2 ring system is assumed to be square and planar. The Cl-Co-Cl'(bridge) bond angle is estimated as 135°. The outer Co-Cl bond lengths are estimated from that for $CoCl_2$ (3), while the ring Co-Cl'(bridge) bond lengths are estimated to be somewhat larger. The principal moments of inertia are: $I_A = 28.4941 \times 10^{-39}$, $I_B = 203.8550 \times 10^{-39}$, and $I_C = 232.3490 \times 10^{-39}\ g\ cm^2$.

The three observed vibrational frequencies (ν_9, ν_{11}, and ν_{12}) are taken from the matrix-infrared study of Thompson and Carlson (5). The rest of the frequencies except for ν_{10} are estimated by comparison with *similar data for other dimeric molecules* (3). The value for ν_{10} (143 cm^{-1}) was obtained by Thompson and Carlson (5) from a simplified normal coordinate analysis. Also, Leroi et al. (4) *obseved a band at 422±10* cm^{-1} *in the infrared spectrum of gaseous* $CoCl_2$ *near* 1000 K. The band was assigned to an outer-bond stretching frequency of the dimer. This interpretation agrees with our adopted results. The electronic levels and quantum weights are arbitrarily taken equal to those for the monomer (3).

Enthalpy of Formation

Beusman (1) reported the partial pressures of the monomer and dimer in the temperature range from 980-1167 K using both a static method to determine the total pressures of these two species and a transpiration method to determine the ratio of monomer to dimer. Schoonmaker and Porter (2) determined mass spectrometrically the partial pressures of the monomer and dimer in the temperature range from 621-658 K. Based on the combination of these two sets of partial pressure data, we have derived a smoothed equation log Kp(atm) = -7549/T + 6.506 for $Fe_2Cl_4(g) = 2\ FeCl_2(g)$. 2nd law analysis of the equilibrium constants gives the enthalpy and the entropy of the dimerization at 298 K as $\Delta_d H° = -35.7$ kcal mol^{-1} and $\Delta_d S° = -32.0$ cal K^{-1} mol^{-1} which lead to the adopted $\Delta_f H°(Fe_2Cl_4, g, 298.15\ K) = -103.1$ kcal mol^{-1} (-431.370 ± 4.2 kJ mol^{-1}) and $S°(Fe_2Cl_4, g, 298.15\ K) = 111.0$ cal K^{-1} mol^{-1}, using $\Delta_f H°(FeCl_2, g, 298.15\ K) = -33.7$ kcal mol^{-1} and $S°(FeCl_2, g, 298.15\ K) = 71.50$ cal K^{-1} mol^{-1} (3).

The equilibrium constants derived from the two different experimental techniques are reasonably consistent considering the uncertainties inherent in the problems. Combination of these two sets of data leads to reliable 2nd law heat and entropy since the temperature ranges are different by 400 K.

Heat Capacity and Entropy

A planar structure with D_{2h} symmetry was suggested by Leroi et al. (4), Thompson and Carlson (5). Two iron and two chlorine atoms form a square. The outer Fe-Cl distance is estimated to be the same as in $FeCl_2(g)$ and the square Fe-Cl' distance is assumed to be slightly larger. The Cl-Fe-Cl(bridge) angle is estimated to be 135°. The principal moments of inertia are: $I_A = 31.1433 \times 10^{-39}$, $I_B = 218.7538 \times 10^{-39}$ g cm^2 and $I_C = I_A + I_B$. The electronic levels and quantum weights were arbitrarily estimated to be the same as in $FeCl_2(g)$.

There are only four vibrational frequencies observed in the matrix isolated infrared spectrum, $\nu_{10} = 110\ cm^{-1}$ and $\nu_{12} = 436.2\ cm^{-1}$ (5), $\nu_9 = 325\ cm^{-1}$, $\nu_{11} = 249\ cm^{-1}$ and $\nu_{12} = 438\ cm^{-1}$ (6). The other eight fundamental vibrational frequencies were estimated by comparison with other dimer molecules and also adjusted so that they give $S°(Fe_2Cl_4, g, 298.15\ K) = 111.0$ cal K^{-1} mol^{-1} which has been discussed in the earlier Enthalpy of Formation part. The order of the frequencies listed above is arbitrary and not related to their species types.

Bond Distance: Mg-Cl = [2.18] Å Mg-Cl'(ring) = [2.3] Å

Bond Angles: Cl'-Mg-Cl'(in ring) = [90°] Cl-Mg-Cl' = [135°]

Product of the Moments of Inertia: $I_A I_B I_C = 1.3313 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

References relative to the monomer-dimer ratio in magnesium chloride vapor are given in the discussion for monomeric ideal gas. The selected best value for the enthalpy of dimerization at 900 K is -39.2 kcal mol^{-1}. Combined with enthalpy of formation data for the monomer and the heat capacity of the dimer, this yields $\Delta_f H°(298.15\ K) = -228.10$ kcal mol^{-1}.

Heat Capacity and Entropy

A planar structure with D_{2h} symmetry was assumed, with the outer Mg-Cl distance the same as in $MgCl_2$ and the ring Mg-Cl distance slightly larger. The ring was taken to be square, and the Cl-Mg-Cl' angle 135°. This structure gives individual moments of inertia of $I_A = 31.12 \times 10^{-39}$ g cm^2, $I_B = 191.86 \times 10^{-39}$ g cm^2 and $I_C = I_A + I_B$.

A reasonable set of frequencies was estimated by comparison with $MgCl_2$ monomer and other dimer molecules. The single observed frequency is from Buchler and Klemperer (1) who erroneously ascribed it to the bending mode of the monomer. The estimated values were adjusted until the entropy of dimerization at 900 K was -29.9 kcal mol^{-1}, as selected in the discussion for ideal monomeric gas. The calculated thermodynamic properties of monomer and dimer give total vapor pressures in good agreement with experiment and yield a boiling point for magnesium chloride of 1624 K at one atmosphere pressure.

PREVIOUS: December 1969 (1 atm) CURRENT: December 1969 (1 bar)

MOLYBDENUM CHLORIDE ($MoCl_4$) CRYSTAL M_r = 237.752

$S°(298.15\ K) = [223.84 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 590\ K$

$\Delta_f H°(0\ K)$ = *Unknown*
$\Delta_f H°(298.15\ K) = -477.0 \pm 8\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [16.736 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = 114\ kcal\ mol^{-1}$ was determined by Shchukarev et al. (1) by solution calorimetry. The authors measured the enthalpy of solution of $MoCl_4$ in the aqueous solvent $FeCl_3$ + HCl and obtained the enthalpy of formation from a comparison with the enthalpy of solution of $MoCl_5$ measured in the same solvent.

The decomposition pressures of $2MoCl_5(cr) = 2MoCl_4(cr) + Cl_2(g)$ (80 ~ 150°C) were measured manometrically by Saeki and Matsuzaki (2). From the reported data we evaluate the enthalpy change for the above reaction by 3rd law analysis. Based on $\Delta_f H°(MoCl_5, cr, 298.15\ K) = -126\ kcal\ mol^{-1}$ and the 3rd law $\Delta_r H°(298.15\ K) = 24.132\ kcal\ mol^{-1}$, we obtain $\Delta_f H°(MoCl_4, cr, 298.15\ K) = -113.94\ kcal\ mol^{-1}$, which is in very good agreement with the value reported by Shchukarev et al. (1).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of $WCl_4(cr)$. The estimated $S°(298.15\ K) = 53.5\ cal\ K^{-1}\ mol^{-1}$ is based on the assumption that the entropy difference between $MoCl_4(cr)$ and $MoCl_5(cr)$ is about the same as that between $WCl_4(cr)$ and $WCl_5(cr)$. The entropy obtained from the second law analysis of the data of Saeki and Matsuzaki (2) agrees with the adopted one within the error of the vapor pressure data.

Fusion Data

See the liquid table for details.

PREVIOUS: CURRENT: December 1968

MOLYBDENUM CHLORIDE ($MoCl_4$) LIQUID M_r = 237.752

$S°(298.15\ K) = [245.525]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 590\ K$

$\Delta_f H°(298.15\ K) = [-462.837]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [16.736 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(MoCl_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MoCl_4, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(590\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7 cal K^{-1} g-atom. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} is taken from Gutmann (1). $\Delta_{fus} H°$ is estimated such that the derived $\Delta_f G°$ for $MoCl_4(\ell)$ yields a reasonable boiling point which is expected to be between 600 and 700 K from comparisons with related compounds.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change ($\Delta_r G°$) of the following process $MoCl_4(\ell) = MoCl_4(g)$ is zero. The difference between $\Delta_f H°$ for $MoCl_4(\ell)$ and $MoCl_4(g)$ at T_{vap} is the enthalpy of vaporization.

MOLYBDENUM CHLORIDE ($MoCl_4$) IDEAL GAS M_r = 237.752

$S°(298.15\ K) = [371.941]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-388.91 \pm 12.6]\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-384.93 \pm 12.6]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	[3]
[10000]	[3]
[30000]	[3]

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
[390](1)	[410](3)
[120](2)	[120](3)

Point Group: T_d σ = [12]

Bond Distance: Mo-Cl = [2.27] Å

Bond Angle: Cl-Mo-Cl = [109.4712]°

Product of the Moments of Inertia: $I_A I_B I_C = [5.29405 \times 10^{-112}]\ g^3\ cm^6$

Enthalpy of Formation

Shchukarev et al. (1), derived the value $\Delta_f H°(MoCl_4, g, 298.15\ K) = -89\ kcal\ mol^{-1}$ from the decomposition pressures of $2MoCl_3(cr) = MoCl_2(cr) + MoCl_4(g)$, 480-600°C, measured by a transpiration method. However, this value is adjusted to be -92±3 $kcal\ mol^{-1}$, in order to obtain a reasonable boiling point (see the liquid table for details).

Heat Capacity and Entropy

Vibrational frequencies and quantum weights are estimated by comparison with those of $WCl_4(g)$. The molecular configuration is assumed to be tetrahedral similar to those of $WCl_4(g)$, $SiCl_4(g)$, $TiCl_4(g)$ and $PbCl_4(g)$. The bond distance is estimated to be the same as that of $MoCl_5(g)$. The principal moments of inertia are $I_A = I_B = I_C = 80.8964 \times 10^{-39}\ g\ cm^2$. The low lying electronic levels are estimated to be 0, 10000, and 30000, all triplets, by comparison with those of $WCl_4(g)$.

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

Molybdenum Chloride ($MoCl_4$) $Cl_4Mo_1(g)$

$S°(298.15\ K) = [172.8 \pm 16.7]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 484\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -671.11 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 45.380 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

Shchukarev, et al. (1) measured calorimetrically the enthalpies of reaction (1) and (2) at 298.15 K as -131.5±0.3 and -13.6±0.11 kcal mol^{-1}, respectively. The reactions are given as follows:

(1) $WOCL_4(cr) + 6\ NaOH(aq, 16.3\ H_2O) \rightarrow Na_2WO_4(aq, 190000\ H_2O) + 4\ NaCl(aq, 50000\ H_2O) + 3\ H_2O(\ell)$

(2) $H_2WO_4(cr) + 2\ NaOH(aq, 16.3\ H_2O) \rightarrow Na_2WO_4(aq, 20000\ H_2O) + 2\ H_2O(\ell)$

Based on these data and the enthalpies of dilution for NaOH(aq)[2], and $Na_2WO_4(aq)$[3], we obtain $\Delta_r H°(298.15\ K) = -118.0 \pm 1.6$ kcal mol^{-1} for $WOCl_4(cr) + 4OH^-(aq, \infty) \rightarrow H_2WO_4(cr) + 4\ Cl^-(aq, \infty) + H_2O(\ell)$. This leads to $\Delta_r H°(WOCl_4, cr, 298.15\ K) = 160.4 \pm 2$ kcal mol^{-1}, using $\Delta_f H°(H_2WO_4, cr, 298.15\ K) = -270.5 \pm 0.4$ kcal mol[5].

Heat Capacity and Entropy

$C_p°(300\ K) = 35.0$ cal $K^{-1}\ mol^{-1}$ is estimated using Kopp's rule. Since the melting point of $WOCl_4(cr)$ is approximately 500 K, which is relatively low for oxygen to reach its maximum contribution, we estimate $C_p°(500\ K) = 40.0$ cal $K^{-1}\ mol^{-1}$ based on the values for $WO_2(cr)$, $WO_3(cr)$ and $WCl_6(cr)$.

The entropy, $S°(298.15\ K) = 41.3$ cal $K^{-1}\ mol^{-1}$, is calculated from $\Delta S°(457\ K) = 44.5$ cal $K^{-1}\ mol^{-1}$ for $WOCl_4(cr) \rightarrow WOCl_4(g)$ obtained from the 2nd law analysis of the vapor pressure equation given by Shchukarev and Suvorov (4). See $WOCl_4(g)$ table (Mar. 31, 1967) for details.

It is surprising that this entropy is smaller than the corresponding value for $WOF_4(cr)$. See $WOF_4(cr)$ table (Mar. 31, 1967) for details.

Fusion Data

T_{fus} is calculated as the temperature at which the Gibbs energies of formation of crystal and liquid are equal. The difference between the enthalpies of formation of crystal and liquid at the melting point is $\Delta_{fus} H°$. This $\Delta_{fus} H°$ is derived from 2nd law analyses of the vapor pressure equation determined by Shchukarev and Suvorov (4). See $WOCl_4(\ell, g)$ tables (Mar. 31, 1967) for details.

TUNGSTEN CHLORIDE OXIDE ($OWCl_4$) LIQUID M_r = 341.6614

$S°(298.15\ K) = [253.565]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 484\ K$

$\Delta_f H°(298.15\ K) = [-630.573]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 45.380 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(WOCl_4, \ell, 298.15\ K)$, is calculated from that of the gas by subtracting the enthalpy of vaporization, $\Delta_{vap}H°(298.15\ K) = 13.643\ kcal\ mol^{-1}$. The latter is obtained by the 3rd law method from the vapor pressure equation given by Shchukarev and Surorov (1). 2nd law analysis gives $\Delta_{vap}H°(501.9\ K) = 10.32\ kcal\ mol^{-1}$ [$(\Delta_{vap}H°(298.15\ K) = 13.643\ kcal\ mol^{-1}$] and the boiling point $T_{vap} = 493\ K$. Earlier data reported by Shchukarev et al. (2) have been revised and they are not used here.

Heat Capacity and Entropy

The heat capacity is assumed to be constant at $7.25\ cal\ K^{-1}\ g\text{-}atom^{-1}$ as suggested by Kubaschewski and Evans (3).

The entropy, $S°(298.15\ K) = 60.6\ cal\ K^{-1}\ mol^{-1}$, is calculated from $\Delta S°(501.9\ K) = 20.9\ cal\ K^{-1}\ mol^{-1}$ for $WOCl_4(\ell) \rightarrow WOCl_4(g)$ obtained from the 2nd law analysis of the vapor pressure equation given by Shchukarev and Suvorov (1).

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which the Gibbs energies of formation of liquid and gas are equal. The difference between the enthalpies of formation of liquid and gas at the boiling point is $\Delta_{vap}H°$.

Enthalpy of Formation

The enthalpy formation, $\Delta_f H°(WOCl_4, g, 298.15\ K) = -137.0\ kcal\ mol^{-1}$, is calculated from $\Delta_r H°(298.15\ K) = 23.4\ kcal\ mol^{-1}$ for $WOCl_4(cr) \rightarrow WOCl_4(g)$. The latter is obtained by the 3rd law method from the vapor pressure equation given by Shchukarev and Suvorov (1). Second law analysis gives $\Delta_r H°(457.2\ K) = 21.9\ kcal\ mol^{-1}$ ($(\Delta_r H°(298.15\ K) = 23.4\ kcal\ mol^{-1}$).

*Earlier data reported by Shchukarev et al. (2) have been revised and they are not used here.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $SOF_4(g)$, reported by Goggin et al. (3). The bond distances W-O and W-Cl are estimated to be the same as those in $WO_3(g)$ and $WCl_6(g)$, respectively. The principal moments of inertia are: $I_A = 67.5706 \times 10^{-39}$, $I_B = 82.6053 \times 10^{-39}$ and $I_C = 105.2432 \times 10^{-39}\ g\ cm^2$.

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for $SOF_4(g)$, (3), $MoOCl_4(g)$ (4), $WO_2Cl_2(g)$ (5), $CrO_2Cl_2(g)$ (6, 7), $WO_3(g)$ (8), and $WCl_6(g)$ (8). The frequencies are not listed in point group order.

Ground State Quantum Weight: [1] $\sigma = 12$

Point Group: T_d

Bond Distance: Pb-Cl = 2.43 Å

Bond Angle: Cl-Pb-Cl = [109.4712°]

Product of the Moments of Inertia: $I_A I_B I_C = [7.96655 \times 10^{-112}]\ g^3\ cm^6$

Enthalpy of Formation

The adopted $\Delta_f H°(0\ K) = -131.6 \pm 20$ kcal mol^{-1} is derived from the dissociation energy for the process $PbCl_4(g) = Pb(g) + 4Cl(g)$. D° = 12.70 eV is estimated from an intercomparison of the lead mono-, di-, and tetra- halides (1). The adopted D° value for $PbCl_4(g)$ is greater than the D° value for $PbCl_2(g)$ by a factor of 2.02. The auxiliary values $\Delta_f H°(Pb, g, 0\ K)$ = 46.91 kcal mol^{-1} (1) and $\Delta_f H°(Cl, g, 0\ K)$ = 28.587 kcal mol^{-1} (1) are used. $\Delta_f H°(PbCl_4, g, 298.15\ K) = -132.0 \pm 20$ kcal mol^{-1} is calculated from $\Delta_f H°(0\ K)$.

Heat Capacity and Entropy

The bond distance is given by Lister and Sutton (2). The vibrational frequencies are those determined by Clark nd Hunter (3) from Raman spectra of $PbCl_4$ in n-pentane solution. Clark and Hunter (3) also observed an electronic transition at 35,250 cm^{-1} which they claim is the lowest allowed electronic transition of the molecule. The present calculations assume a singlet electronic gound state.

The principal moments of inertia are: $I_A = I_B = I_C = 92.7022 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

Gross et al. (1) measured the enthalpy of formation of $SiCl_4(\ell)$ by the direct chlorination of silicon in a bomb calorimeter. Corrections for the difference in enthalpy content between liquid and gaseous chlorine at 25°C and 1 atm led to the value of $\Delta_f H°(SiCl_4, \ell, 298.15\ K) = -165.49 \pm 0.16\ kcal\ mol^{-1}$. Combination of $\Delta_f H°(\ell, 298.15\ K)$ with $\Delta_{vap} H°(298.15\ K) = 7.09\ kcal\ mol^{-1}$ gives $\Delta_f H°(SiCl_4, g, 298.15\ K) = -158.4 \pm 0.3\ kcal\ mol^{-1}$ which is adopted in the tabulation.

Schafer and Heine (2) measured both enthalpy of solution of Si(cr) and $SiCl_4(\ell)$ in HF solution containing AgF which gave $\Delta_r H°(298.15\ K) = 42.7 \pm 0.4\ kcal\ mol^{-1}$ for the overall reaction $SiCl_4(\ell) + 4Ag(cr) = Si(cr) + 4AgCl(cr)$ and led to $\Delta_f H°(SiCl_4, \ell, 298.15\ K) = -164.18\ kcal\ mol^{-1}$ in agreement with the value adopted, using $\Delta_f H°(AgCl, cr, 298.15\ K) = -30.37\ kcal\ mol^{-1}$ (3).

Wolf (4) determined the heats of solution of $SiCl_4(\ell)$ and $Na_2SiO_3.8H_2O(cr)$ in NaOH solution and derived $\Delta_r H°(298.15\ K) = -129.3\ kcal\ mol^{-1}$ for $SiCl_4(\ell) + 13NaOH(27.8\ H_2O) = Na_2SiO_3(cr) + 4NaCl + 3H_2O(\ell) + 7NaOH(52.14\ H_2O)$ which leads to $\Delta_f H°(SiCl_4, \ell, 298.15\ K) = -166.7 \pm 2\ kcal\ mol^{-1}$, using all JANAF auxiliary data and heats of dilution of NaOH from Parker (5). However, Wolf's data are suspect due to uncertainties in how he converted his data from Na_2SiO_3(calorimetric solution) to $Na_2SiO_3(cr)$. Beezer and Mortimer (6) measured the heat of solution $\Delta_r H°(298.15\ K) = -97.0\ kcal\ mol^{-1}$ for $SiCl_4(\ell) + 185\ HF(4.335\ H_2O) = 4HCl(11\ H_2O) + [H_2SiF_6, 179\ HF, 758\ H_2O]$ and combined with those of Good (7) for $[H_2SiF_6, 41\ HF, 174\ H_2O]$ solution by neglecting the unknown heats of dilution between the two calorimetric solutions and obtained $\Delta_f H°(\ell, 298.15\ K) = -169.9\ kcal\ mol^{-1}$ which is in poor agreement with the value adopted. In both the measurements of Woof and Beezer, the final state of the calorimetric solution is not well defined or not well known, thus it leads to large uncertainties in their results.

Other calorimetric studies involving aqueous hydrolysis of $SiCl_4(\ell)$ to form SiO_2(colloidal solution) have been reviewed by Gross et al. (1). Since the SiO_2(colloidal solution) is an ill-defined state, the heat of formation of $SiCl_4(\ell)$ derived from hydrolysis data is quite unreliable.

Heat Capacity and Entropy

Morino and Murata (8) measured the adopted bond distance by electron diffraction. Their value was confirmed by Ryan and Hedberg (9). Morino et al. (10) observed the adopted vibrational frequencies from the infrared and Raman spectra from the vapor. Infrared data of Smith (11) confirm that ν_3 is about 12 cm^{-1} larger in the vapor than in the liquid. The principal moments of inertia are: $I_A = I_B = I_C = 63.8879 \times 10^{-38}\ g\ cm^2$.

Vaporization Data

Vapor pressure data ranging from 20° below T_{fus}(supercooled liquid) to 10° above T_{vap} are in reasonable agreement as summarized below. The analysis is based on fugacities calculated from vapor pressures by the approximation of Pitzer (19) using T_c = 506 K (20), P_c = 37.1 atm (21) and ω = 0.26. At 298.15 K the calculated f/P is 0.982 compared with 0.984 observed by Wood (22). The analysis also presumes a linear variation of the liquid phase Cp based on 33.3 $calK^{-1}\ mol^{-1}$ at 210 K and 34.2 at 300 K. The latter value is from data of Vold (17) since earlier data (77-294 K) of Latimer (18) appear to have large positive bias below T_{fus}. The Cp at 210 K assumes Latimer's value to have about 1 percent bias by analogy with his data for $CCl_4(\ell)$.

PREVIOUS: December 1970 (1 atm) CURRENT: December 1970 (1 bar)

$S°(298.15\ K) = 209.069 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 249.05\ K$

$\Delta_f H°(0\ K) = [-818.798]\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-815.026]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 9.966\ kJ\ mol^{-1}$

Heat of Formation

The enthalpy of formation, $\Delta_f H°(298.15\ K)$, of $TiCl_4(cr)$ is calculated from the corresponding quantity for $TiCl_4(\ell)$ and the values of $H°(249.05\ K) - H°(298.15\ K)$ for both crystal and liquid.

Heat Capacity and Entropy

The heat capacity of $TiCl_4(cr)$ has been reported by Latimer (1) and by Furukawa (2). The data from the latter investigation are adopted. These data lead to a value of 44.5 cal K^{-1} mol^{-1} for $S°(249.05\ K)$. This compares with Latimer's value (1) of 43.8 cal K^{-1} mol^{-1} for the same quantity. The heat capacity of the solid is extrapolated to a value of 18R at 600 K, based on the known heat capacities of $TiBr_4(cr)$ and $TiI_4(cr)$. The hypothetical entropy at 298.15 K is base don the integration of the extrapolated curve and the value at the melting point.

Melting Data

The triple point is reported to be 249.05 K, with a measured enthalpy of fusion of 2.382 kcal mol^{-1}, by Furukawa (2). Latimer (1) reported values of 248.0 K and 2.233 kcal mol^{-1} for these quantities. The former data are adopted.

$\Delta_{fus} H° = 9.966\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(TiCl_4, \ell, 298.15\ K)$, is calculated from that of $TiCl_4(g)$ and the value of $\Delta_{vap}H°(298.15\ K)$. The value of $\Delta_{vap}H°(298.15\ K)$ is determined from 2nd and 3rd law analyses of fugacity as follows.

Source	Method	T/K	Data Points	$\Delta_{vap}H°(298.15\ K)$ 2nd law	3rd law	Drift cal $K^{-1}mol^{-1}$	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

* Two Points rejected to failure of a statistical test

** Three points rejected due to failure of a statistical test

*** Selected points from extensive data

3rd law analyses of the several vapor pressure sets result in drifts which are proportional to the mean temperatures. Conversion of these data to fugacity eliminates this temperature dependence and the drifts are then scattered randomly about a constant value. This constant value is made to be essentially zero by methods described on the $TiCl_4(g)$ table. The conversion to fugacity was made using Pitzer's method for normal fluids (5). The calculation was carried out using the value of 45.7 atm. for the critical pressure, P_c, reported by Minzer (6) and estimated values of 643±15 K for the critical temperature, T_c, and 0.23±0.03 for the acentric constant, ω. Schafer et al. (7) reported a calorimetric determination of $\Delta_{vap}H°(298.15\ K)$. Their value of 9.9±0.02 kcal mol^{-1} was used to check the reliability of their equipment, assuming that the vapor pressure data (3) gave a more accurate determination of $\Delta_{vap}H°(298.15\ K)$. The adopted value of $\Delta_{vap}H°(298.15\ K)$ is 9.82±0.02 kcal mol^{-1}.

Heat Capacity and Entropy

The entropy and heat capacity of $TiCl_4(\ell)$ has been measured by Furukawa (8). His reported values are adopted.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is taken as the temperature at which Kp = 1 for the reaction $TiCl_4(\ell) = TiCl_4(g)$. The vapor pressure data are discussed above.

$\Delta_f H°(0\ K) = -761.58 \pm 3.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -763.16 \pm 3.8\ kJ\ mol^{-1}$

Vibrational Frequences and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
368 (1)	498.5(3)
111 (2)	131 (3)

Ground State Quantum Weight: 1 $\sigma = 12$

Point Group: T_d

Bond Distance: Ti-Cl = 2.185 Å

Bond Angle: Cl-Ti-Cl = 109.4712°

Product of the Moments of Inertia: $I_A I_B I_C = 4.21057 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ of $TiCl_4(g)$ and $TiCl_4(\ell)$ has been measured by several investigators. The results of these measurements are as follows.

Source	Method	Reaction	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} $TiCl_4(\ell)$	$TiCl_4(g)$
Johnson et al. (1)	Calorimetric	$Ti(cr) + 2\ Cl_2(g) = TiCl_4(g)$	(-192.2)	-182.4±0.7
Farber and Darnell (2)	Equilibrium	$TiO_2(cr) + 4\ HCl(g) = TiCl_4(g) + 2\ H_2O(g)$	(-192.7)	-182.9±0.5
Skinner and Ruehrwein (3)	Calorimetric	$Ti(cr) + xCl_2(g) = [TiCl_4 + (x-2)Cl_2]$ soln	-190.3±3.0	(-180.5)
Gross et al. (4)	Calorimetric	$Ti(cr) + xCl_2(\ell) = [TiCl_4 + (x-2)Cl_2]$ soln	-191.5±0.3	(-181.7)
Krieve et al. (5)	Calorimetric	$Ti(cr) + xCl_2(g) = [TiCl_4 + (x-2)Cl_2]$ soln	-190.0±0.4	(-180.2)
Thomsen (6)		$TiCl_4(\ell) + 2\ H_2O(\ell) = 4\ HCl_{(0.002\ m)} + TiO_2(cr)$	-194.5	(-184.7)

The chosen value of $\Delta_f H°(298.15\ K)$ is that reported by Johnson et al. (1). This investigation has the advantage of being independent of the enthalpy of vaporization of chlorine and any heats of solution in deriving the value of the enthalpy of formation.

Heat Capacity and Entropy

The adopted value for the interatomic distance is that reported by Kimura et al. (7). The tetrahedral structure was established by the Raman work of Bhagavantam (8). The vibrational frequencies determined from the infrared and Raman spectra of $TiCl_4$ by Hawkins and Carpenter (9) are adjusted downward 8 cm^{-1} for ν_2 and ν_4 so that the enthalpies of vaporization determined by both 2nd and 3rd law methods are in agreement. See $TiCl_4(\ell)$ table for details. The principal moments of inertia are: $I_A = I_B = I_C = 74.9515 \times 20^{-39}\ g\ cm^2$.

PREVIOUS: December 1967 (1 atm) CURRENT: December 1967 (1 bar)

TUNGSTEN CHLORIDE (WCl_4) CRYSTAL M_r = 325.662

$S°(298.15\ K)$ = [198.322] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K)$ = -443.09 ± 62.8 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(WCl_4, cr, 298.15\ K)$ = -105.9 kcal mol^{-1} is calculated from $\Delta_r H°(298.15\ K)$ = 58.9 kcal mol^{-1} for 3 $WCl_4(cr)$ = $WCl_2(cr)$ + 2 $WCl_5(g)$. The value of $\Delta_r H°(298.15\ K)$ is calculated by the 3rd law method from decomposition pressure data in the temperature range from 354°C to 436°C reported by Shchukarev et al. (1). The 2nd law, $\Delta_r H°(298.15\ K)$ = 73.6±7.9 kcal mol^{-1} and the 3rd law drift is -24±12 cal K^{-1} mol^{-1} which would correspond to a total entropy discrepancy of -8±4 cal K^{-1} mol^{-1} per mole of WCl_4. This entropy discrepancy is probably within the combined uncertainty of the data and the estimated entropies for the three species. Shchukarev et al. (2) have shown that decomposition pressures are essentially independent of the composition in the solid phase until $WCl_4(cr)$ is almost completely decomposed to $WCl_2(cr)$. This is consistent with the assumption of solid phase activities of unity which we have used in the equilibrium analysis.

Heat Capacity and Entropy

$C_p°(298.15\ K)$ = 6.2 cal K^{-1} g-atom and $C_p°(700\ K)$ = 7.25 cal K^{-1} g-atom are estimated using the method described by Kubaschewski and Evans (3). Between 298 and 700 K, which is near the decomposition temperature, the heat capacity is obtained by linear interportion.

The entropy of $WCl_4(cr)$, $S°(298.15\ K)$ = 47.4 cal K^{-1} mol^{-1}, is estimated by the method of Latimer (4).

Decomposition Data

T_{dcm} = 771 K (f = 1 atm) is calculated as the temperature at which the Gibbs energy change of the reaction 3 $WCl_4(cr)$ = $WCl_2(cr)$ + 2 $WCl_5(g)$ approaches zero. We have also derived an approximate value of decomposition temperature, T_{dcm} = 744 K, by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by Shchukarev et al. (5). The difference between the two decomposition temperatures is related to the 2nd law entropy and the adopted entropy.

Point Group: $[T_d]$ σ = [12]
Bond Distance: W-Cl = [2.26] Å
Bond Angle: Cl-W-Cl = [109.4712]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [5.15566 x 10^{-112}] $g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(WCl_4, g, 298.15\ K) = -80.3\ kcal\ mol^{-1}$ is calculated from $\Delta_r H° = 37.7\ kcal\ mol^{-1}$ for $WCl_6(g) + WCl_4(g) + Cl_2(g)$. The value of $\Delta_r H°(298.15\ K)$ is calculated by the 3rd law method from the equation for log Kp given by Shchukarev and Suvorov (1). The 2nd law $\Delta_r H°(298.15\ K)$ is 43.6 kcal mol^{-1} and the 3rd law drift is -9.6 cal $K^{-1}\ mol^{-1}$.

Heat Capacity and Entropy

The molecular configuration is assumed to be tetrahedral similar to those of $SiCl_4$, $TiCl_4$, VCl_4, $GeCl_4$, $ZrCl_4$, $SnCl_4$, $PbCl_4$. The bond distance is estimated to be the same as that in $WCl_6(g)$. The principal moments of inertia are: $I_A = I_B = I_C$ = 80.1853 x 10^{-39} g cm^2.

All vibrational frequencies are estimated from those of $SiCl_4$, $TiCl_4$, VCl_4, $GeCl_4$, $SnCl_4$ and $PbCl_4$ given by Nakamoto (2).

If it is considered that the metal atoms are effectively ionized, then the W^{4+} will have 2 d electrons in a field of chloride ions. The electronic splitting would be roughly the inverse of that in $NiCl_2(g)$, as given by DeKock and Gruen (3), where Ni has a d^8 configuration. By analogy with the splitting in $NiCl_2$, the low lying electronic levels are estimated to be 10000 cm^{-1} and 30000 cm^{-1}, both triplets.

PREVIOUS December 1966 (1 atm) CURRENT: December 1966 (1 bar)

ZIRCONIUM CHLORIDE ($ZrCl_4$) CRYSTAL M_r = 233.032

$S°(298.15\ K) = 181.42 \pm 0.7\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 710 \pm 2\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -981.59 \pm 1.7\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -980.52 \pm 1.7\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 50.2 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

Gal'chenko et al. (1) determined enthalpy of formation of $ZrCl_4$(cr) by the direct chlorination of highly pure Zr metal in a bomb calorimeter. Complete chlorination of the metal was accomplished as indicated by the absence of unreacted metal and of lower chlorides. They reported $\Delta_f H°(ZrCl_4, cr, 298.15\ K) = -234.17 \pm 0.28\ kcal\ mol^{-1}$.

Gal'chenko et al. (2) had also earlier determined the enthalpy of formation of $ZrCl_4$(cr) by a similar technique and reported $-234.35 \pm 2.1\ kcal\ mol^{-1}$. Gross et al. (6) measured calorimetrically the chlorination of Zr(cr) with liquid chlorine. His results led to $\Delta_f H°(298.15\ K) = -234.7 \pm 0.4\ kcal\ mol^{-1}$ for $ZrCl_4$(cr). We adopt $\Delta_f H°(298.15\ K) = -234.35 \pm 0.4\ kcal\ mol^{-1}$ which is a weighted mean of these three studies. This adopted value is identical to that suggested by NBS (4).

Less reliable studies leading to $\Delta_f H°(298.15\ K)$ values have been reported by Siemonsen and Siemonsen (7), and Beck (8). Equilibrium studies by Hildenbrand et al. (3) and Morozov and Korshunov (5) suggest $\Delta_f H°(298.15\ K)$ values 1-3 kcal mol^{-1} less negative than our adopted value.

Heat Capacity and Entropy

Todd (9) measured the low temperature heat capacities from 52.6 to 296.7 K, and made an extrapolation to 0 K which yielded an entropy of 8.12 cal $K^{-1}\ mol^{-1}$ at 51 K. We adopt the measured heat capacities but make our own extrapolation to 0 K, based on the ratio of the measured heat capacities of ZrF_4 (10), TiF_4 (11) and $TiCl_4$ (12) from 6 to 50 K. This extrapolation gives $S°(50\ K) = 6.758 \pm 0.7$ cal $K^{-1}\ mol^{-1}$ which is adopted. Coughlin and King (13) measured high temperature enthalpy data from 335.9 to 566.8 K by drop calorimetry. Their data are smoothly joined with Todd's low temperature heat capacities.

Fusion Data

The melting point, $T_{fus} \approx 710 \pm 2$ K, has been observed by Rahlfs and Fischer (14), Palko et al. (15), and Denisova et al. (16, 17). Nisel'son (18) observed a melting temperature of 708.7 K. Heat of melting data may be extracted from Palko et al. (15) and Denisova et al. (16, 17). A weighted average $\Delta_{fus} H° = 12 \pm 3$ kcal mol^{-1} is adopted for the heat of melting.

Sublimation Data

Several sets of sublimation studies are summarized below, using a 2nd and 3rd analysis.

(21)	--	eqn	376-493	26.59	26.44	-0.4

(a)3, (b)2, (c)1 points rejected due to failure of a statistical test.

A mean of the 3rd law values, $\Delta_{sub}H°(298.15\ K) = 26.42 \pm 0.12$ kcal mol^{-1}, is adopted. The sublimation temperature, T_{sub}, is obtained from the Gibbs energy crossover between the crystal and gas. Since T_{sub} is lower than T_{fus}, the liquid phase is thermodynamically unstable at normal conditions.

In analyzing the vapor pressures for the sublimation studies, corrections were made for non-ideality by means of the equation $\Delta G°/T = -R\ln p - Bp/T$. The Bertholet equation of state and the critical constants $T_c = 776.65$ K and $p_c = 57.4$ atm as determined by Nisel'son and Sokolova (22) are used to calculate B.

Zirconium Chloride ($ZrCl_4$) Cl_4Zr_1(cr)

$S°(298.15\ K) = 367.72 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -868.68 \pm 2.1\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -869.98 \pm 2.1\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
377(1)	418(3)
98(2)	113(3)

Ground State Quantum Weight: [1] $\sigma = 12$
Point Group: T_d
Bond Distance: 2.32 ± 0.02 Å
Bond Angle: Cl-Zr-Cl = 109.4712°
Product of the Moments of Inertia: $I_A I_B I_C = 6.03340 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation of gaseous $ZrCl_4$, $\Delta_f H°(298.15\ K) = -207.76 \pm 0.5$ kcal mol^{-1} is calculated from the enthalpies of formation and sublimation of the crystal (1).

Hildenbrand et al. (14) determined the equilibrium constants by the transpiration method for the reaction: $ZrO_2(cr) + 4\ HCl(g) = ZrCl_4(g) + 2\ H_2O(g)$. 2nd and 3rd law analyses for their data are given below. The enthalpy of formation derived from this study is in fair agreement with the value adopted.

Series	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
I	10	1171-1373	28.94±0.44	29.16±0.15	0.17±0.34	-205.80
II	9	1169-1374	31.36±0.60	29.65±0.28	-1.19±0.47	-205.11

Heat Capacity and Entropy

The adopted vibrational frequencies are from the work of Clark et al. (2, 3), who recorded the Raman spectra of $ZrCl_4$ in the vapor phase (380-420°C). These studies indicated that $ZrCl_4$ is a tetrahedral monomer in the vapor phase. Shimanouchi (4), in his compilation of molecular vibrational frequencies, adopted the values of Clark et al. (2, 3) for $ZrCl_4(g)$. Pontrelli (5) also observed in the Raman spectra all four fundamental vibrational frequencies (376, 99, 418, and 110 cm^{-1}). These values are in excellent agreement with those of Clark et al. (2, 3).

Other experimental studies involving the vibrational frequencies are as follows. Wilmshurst (6) observed one fundamental vibrational frequency (421 cm^{-1}) in the infrared spectrum of $ZrCl_4$ vapor, while Buchler et al. (7) found the same fundamental mode at 423 cm^{-1}. Delwaulle and Francois (8) observed the symmetric stretching vibration (383 cm^{-1}) from the Raman spectra of $ZrCl_4$ in PCl_5 and $POCl_3$. Bobovich (9) reported the symmetric stretching vibration (315 cm^{-1}) from a partially polarized band in his Raman spectrometric studies.

Spiridonov et al. (10) measured the bond distance Zr-Cl = 2.32±0.02 Å in the vapor phase by electron diffraction. The molecule was also found to be a regular tetrahedron. The same bond distance was also reported by Lister and Sutton (11) and Kimura et al. (12). Rahlfs and Fischer (13), through vapor density measurements, had earlier concluded that $ZrCl_4$ was monomeric in the vapor phase. The principal moments of inertia are $I_A = I_B = I_C = 84.4995 \times 10^{-19}\ g\ cm^2$.

Much literature has been published on the inter-relationships between force constants and vibrational frequencies. Since the majority of these articles are based on estimated frequencies, they will not be further discussed or referenced. The same situation is true for thermodynamic tabulations of $ZrCl_4(g)$. One exception is that Clark et al. (2) calculated thermodynamic properties based on their experimental vibrational frequencies. Their tabulation is identical to ours in the range 100-1000 K.

MOLYBDENUM CHLORIDE ($MoCl_5$) CRYSTAL M_r = 273.205

$S°(298.15\ K) = [238.488 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 467\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -527.18 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H°[18.8 \pm 6.3]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is obtained from Shchukarev et al. (1). The authors derived the $\Delta_f H°(MoCl_5, cr, 298.15\ K) = -126\ kcal\ mol^{-1}$ by measuring the enthalpy of solution of $MoCl_5$ in NaOH(aq), which was compared with the enthalpies of solution of MoO_3 and NaCl measured in the same solvent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of WCl_5(cr). S°(298.15 K) is estimated as 57 cal K^{-1} mol^{-1} from the vapor pressure data for $MoCl^5$(cr) + $MoCl^5$(g) measured by Shchukarev et al. (2).

Fusion Data

See the liquid table for details.

MOLYBDENUM CHLORIDE ($MoCl_5$) LIQUID M_r = 273.205

$S°(298.15\ K)$ = [273.807] J K^{-1} mol^{-1}

T_{fus} = 467 K

$\Delta_f H°(298.15\ K)$ = [-510.114] kJ mol^{-1}

$\Delta_{fus} H°$ = [18.828 ± 6.3] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(MoCl_5, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MoCl_5, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(467\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed constant and estimated as 42 cal K^{-1} mol^{-1} or 7 cal K^{-1} g-atom^{-1}. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} is taken from Shchukarev et al. (1). $\Delta_{fus} H°$ is estimated by comparison with that of $WCl_5(cr)$.

Vaporization Data

T_{vap} is the temperature at which the difference between the Gibbs energy of formation for $MoCl_5(\ell)$ and $MoCl_5(g)$ is zero. The difference between $\Delta_f H°(MoCl_5, \ell)$ and $\Delta_f H°(MoCl_5, g)$ at T_{vap} is $\Delta_{vap} H°$.

Saeki	Manometric	$MoCl_5(cr) = MoCl_5(g)$	298 - 474	16.79 ± 0.06	18.94	5.6	-107.06

*Calculation based on third law $\Delta_r H°(298.15\ K)$

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of $NbCl_5$ obtained from infrared and Raman spectra by Carlson (3). *Structure, bond distance* and bond angle are taken from Ewens et al. (4). The principal moments of inertia are: $I_A = 91.0085 \times 10^{-39}$ and $I_B = I_C = 106.1766 \times 10^{-39}\ g\ cm^2$. The electronic levels are estimated to be 0, 7000 and 14000 cm^{-1}, all doublets, by comparison with those of $WCl_5(g)$.

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

$S°(298.15\ K) = [214.05 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 478.9 \pm 1.5\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -797.47 \pm 4.2\ kJ\ mol$

$\Delta_{fus} H° = 33.878 \pm 0.96\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted value for the enthalpy of formation of $NbCl_5(cr)$ is $\Delta_f H°(298.15\ K) = -190.6 \pm 1.0\ kcal\ mol^{-1}$ and is based on the study by Gross et al. (2). This value was determined from measurements of the enthalpy evolved in the reaction Nb(cr) + 5/2 $Cl_2(\ell)$ = $NbCl_5(cr)$. Schafer and Kahlenberg (1) also determined the enthalpy formation of $NbCl_5(cr)$ via calorimetric measurement of the heats of solution of Nb(cr) and $NbCl_5(cr)$ in hydrofluoric acid. Their procedure consisted of five steps; four were determined experimentally and one was based on literature data. Using their data and auxiliary results (7), we calculate $\Delta_f H°(298.15\ K) = -190.0 \pm 1.0\ kcal\ mol^{-1}$ for $NbCl_5(cr)$. This value is in good agreement with our adopted value. Shchukarev et al. (3) determined a $\Delta_f H°(298.15\ K)$ value from a heat of hydrolysis for $NbCl_5(cr)$. A recalculation of this data, using current auxiliary $\Delta_f H°(298.15\ K)$ data for $Nb_2O_5(cr)$ (10), $H_2O(\ell)$ (7), and HCl(g) (10), yields $\Delta_f H°(298.15\ K) = -192.8 \pm 0.7\ kcal\ mol^{-1}$.

Three compilations on Nb species suggested a similar or closely related $\Delta_f H°(298.15\ K)$ value for $NbCl_5(cr)$ (6, 8, 9): in particular, the NBS Technical Note 270 Series suggested -190.6 kcal mol^{-1} (9).

Heat Capacity and Entropy

Keneshea et al. (5) measured the saturation enthalpy increments above 298.15 K for the condensed phases of $NbCl_5$ in a drop calorimeter up to the critical point (804 ± 3 K). A figure presented by Keneshea et al. (5) indicated roughly 30 data points, the lowest occurring at approximately 360 K. The differences between the saturation and standard enthalpy increments for the crystal phase are negligible, so that the heat capacity values which we adopt are those which are derived from the reported enthalpy equation, $H°(T) - H°(298.15\ K) = [-10.53 + 3.535 \times 10^{-2} T] \pm 0.07\ kcal\ mol^{-1}$. This equation is reported to apply to the temerature region 298.15 - 478.9 K.

Schafer and Kahlenberg (1) estimated the heat capacity of $NbCl_5(cr)$ to be given by $C_p° = 38.0 - 3 \times 10^5 T^{-2}\ cal\ K^{-1}\ mol^{-1}$. For the crystal range 298.15 - 478.9 K, these estimated $C_p°$ values vary from 34.63 to 36.69 cal $K^{-1}\ mol^{-1}$. These values are in *fair agreement with the adopted values and were estimated by comparison with* $ZrCl_4(cr)$ *and* $HfCl_4(cr)$. *Amosov* (4) also estimated the heat capacity of $NbCl_5$ based on Neumann and Koppe's rule, $C_p° = 26.71 + 35.2 \times 10^{-3} T\ cal\ K^{-1}\ mol^{-1}$. These latter values vary between 37.20 and 43.57 cal $K^{-1}\ mol^{-1}$ over the region 298.15 - 478.9 K and differ significantly from those $C_p°$ values derived from the experimental data of Keneshea et al. (5).

As there is no low temperature heat capacity data reported in the literature, the entropy of $NbCl_5(cr)$ at 298.15 K is calculated from the equation $\Delta_{sub} S°(298.15\ K) = S°(g, 298.15\ K) - S°(cr, 298.15\ K)$; $S°(g, 298.15\ K) = 96.56\ cal\ K^{-1}\ mol^{-1}$ as given in the $NbCl_5(g)$ table (10) and $\Delta_{sub} S°(298.15\ K) = 45.40\ cal\ K^{-1}\ mol^{-1}$ as obtained Keneshea et al. (5) based on their evaluation of the available vapor pressure data by a modified Σ approach.

Fusion Data

See the liquid table for details.

Sublimation Data

The enthalpy of sublimation, $\Delta_{sub} H°(298.15\ K)$ is the difference between the $\Delta_f H°(298.15\ K)$ values for $NbCl_5(g)$ and $NbCl_5(cr)$. For sublimation studies are summarized in the $NbCl_5(\ell)$ table.

$S°(298.15\ K)$ = [260.970] J K^{-1} mol^{-1}
T_{fus} = 478.9 ± 1.5 K

$\Delta_f H°(298.15\ K)$ = [-773.354] kJ mol^{-1}
$\Delta_{fus}H°$ = 33.878 ± 0.96 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(NbCl_5, \ell, 298.15\ K)$ is calculated from that of $NbCl_5$(cr) by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(478.9 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The liquid phase heat capacity values are derived from the enthalpy equation reported by Keneshea et al. (5). The equation is used for the region 478.9 - 600 K, i.e. that region in which the saturation heat capacity and the heat capacity at constant pressure are essentially the same in value. This equation is used also to extrapolate to 700 K and to an assumed glass transition temperature at T_{gls} = 350 K. Below T_{gls} the heat capacity values are those of the crystal. S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°(298.15\ K)$.

Fusion Data

The adopted value of T_{fus} is that reported by Keneshea et al. (5). This value, 205.7°C or 478.9 K, was obtained by visual observation on four different samples in evacuated capsules. Other values for T_{fus} reported in the literature are: 205.3±1.5 C°(6), 204.8°C (4), 206.8±0.3°C (3), 204.5°C (2) and 204.7°C (1). Earlier determinations of the melting point have been summarized by Schafer and Pietruck (1) and Meyer et al. (3).

The adopted heat of fusion, $\Delta_{fus}H°$ = 8.097±0.23 kcal mol^{-1}, is calculated as the difference at 478.9 K in the enthalpy equations for $NbCl_5(\ell)$ and $NbCl_5$(cr) as reported by Keneshea et al. (5). Meyer et al. (3), from an examination of the $NbCl_5$-$NbOCl_3$ system, reported a value of 8.30±0.4 kcal mol^{-1} for $\Delta_{fus}H°$. Voitovich et al. (4) studied the $NbCl_5$-S_2Cl_2 system and calculated $\Delta_{fus}H°$ = 8.15 kcal mol^{-1}. These two latter values are in excellent agreement with our adopted value.

Johnson and Cubicciotti (6), in their study of the orthobaric densities of $NbCl_5$, discussed the possible molecular behavior of $NbCl_5$. The explanation served to explain the large entropy of melting, $\Delta_{fus}S°$ = 16.91 kcal mol^{-1}. Based on currently available information, they suggested that between the melting point and about 650 K the substance changes from a dimeric solid to a monomeric liquid. This change was suggested to manifest itself in the unusually large volume change (6) (27±2%) and entropy of fusion and in the inverse curvature of the liquid density curve just above the melting point. For additional references, refer to the $NbCl_5$(g) table.

Vaporization Data

T_{vap} is calculated as that temperature for which $\Delta_r G°$ = 0 for the process $NbCl_5(\ell)$ = $NbCl_5$(g). $\Delta_{vap}H°$ is calculated as the difference between the $\Delta_f H°$ values for $NbCl_5$(g) and $NbCl_5(\ell)$ at T_{vap}. Seven vaporization studies are summarized in the $NbCl_5$(g) table. Sheka et al. (2) studied the vapor-liquid equilibrium in the $NbCl_5$-$POCl_3$ system and measured a boiling point (at 760 mm) of 521.7 K for pure $NbCl_5$. The vaporization studies discussed in the $NbCl_5$(g) table which included the boiling point yielded normal boiling points (p = 760 mm) in the range 519.2 - 520.6 K.

Enthalpy of Formation

The vapor pressures over $NbCl_5$(cr) and $NbCl_5$(ℓ) have been measured by seven investigators. The reported vapor pressures are corrected for vapor non-ideality by means of the equation $\Delta G°/T = -R\ln p - Bp/T$. The Berthelot equation of state and critical constants T_c = 803.5±2 K and p_c = 48.2 atm. reported by Johnson et al. (9, 10) are used to calculate B. The corrected vapor pressures are used to calculate $\Delta_r H°(298.15\ K)$ by both 2nd and 3rd law methods. By means of comparison, Nisel'son et al. (6) measured the orthobaric densities of $NbCl_5$(ℓ), as did Johnson et al. (9), and reported T_c = 807 K and p_c = 46 atm.

*One point is rejected due to statistical test.

The adopted value for $\Delta_f H°(298.15\ K)$ of $NbCl_5$(g) is -168.1±2.0 kcal mol^{-1} (-703.330±8.4 kJ mol^{-1}). This value is based on a rounded mean of the 3rd law results for both the sublimation and vaporization studies and the appropriate $\Delta_f H°(298.15\ K)$ value for the crystal or liquid.

Reznitskii (8) measured the enthalpy of chlorination for Nb(cr) and reported $\Delta_f H°(680\ K)$ = -169.1±1 kcal mol^{-1} for the reaction Nb(cr) + 5/2 Cl_2(g) = $NbCl_5$(g). Using auxiliary data for Nb(cr) and Cl_2(g) (11), we calculated $\Delta_f H°(298.15\ K)$ = -170.1±1.0 kcal mol^{-1} for $NbCl_5$(g).

Heat Capacity and Entropy

Monomeric $NbCl_5$(g) was shown by Spiridonov and Romanov (19, 20), using electron diffraction techniques, to have a trigonal bipyramidal structure of D_{3h} symmetry: all the Nb-Cl bond lengths being equal within experimental uncertainty, 2.28±0.2 Å. *Skinner and Sutton (12) earlier used electron diffraction techniques and had suggested the same structure although a square* pyramidal structure was consistent with the experimental results. We adopt the results of Spiridonov and Romanov (19, 20). *The principal moments of inertia are:* $I_A = 91.8121 \times 10^{-39}$ *and* $I_B = I_C = 107.1141 \times 10^{-39}\ g\ cm^2$.

A normal coordinate treatment of $NbCl_5$(g) in the Urey-Bradley force fields was performed by So (22) using the reported vibrational frequencies of Beattie and Ozin (21). This work by So (22) was intended to check the correctness of the reported fundamental frequencies and predict those frequencies which had not been observed (ω_3, ω_4, ω_5). The calculations of So (22) suggested that the ω_5 value reported for $NbCl_5$(g) was incorrect. Beattie and Ozin (21) had recorded the gas phase Raman spectra of $NbCl_5$, $NbBr_5$, $TaCl_5$ and $TaBr_5$ and has assigned ω_5 only in the case of $NbCl_5$. It was noted that this appeared only very weakly in the spectra. We adopt the results of So (22) which support the work of Beattie and Ozin (21) except for the ω_5 assignment.

There are many references in the literature to spectroscopic observations (IR and Raman) of $NbCl_5$ in the solid state, in organic solvents, and in matrices. Many problems arise in any attempt in relating the observed spectra. Niobium pentachloride was shown to be dimeric in the solid phase (13). There are also indications that $NbCl_5$ is dimeric in solution (15, 16, 17).

On the basis of these frequencies and the adopted structure, we calculate S°(298.15 K) = 96.56±0.75 cal K^{-1} mol^{-1}, as was also calculated by So (22). This compares to a value of 90.29 cal K^{-1} mol^{-1} calculated by Gaunt and Ainscough (14) and 95.52 cal K^{-1} mol^{-1} by Werder et al. (18).

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was calculated from the $\Delta_r H°(298.15\ K)$ for the reaction: $PCl_3(g) + Cl_2(g) \rightarrow PCl_5(g)$. A third law calculation using experimental equilibrium constants, and free energy functions from JANAF Tables gave a $\Delta_r H°(298.15\ K) = -20.884\ kcal\ mol^{-1}$. This $\Delta_r H°$ is the average of (1) $\Delta_r H°(298.15\ K) = -20.766 \pm 0.26\ kcal\ mol^{-1}$ and (2) $\Delta_r H°(298.15\ K) = -21.001 \pm 0.24\ kcal\ mol^{-1}$. The first, $\Delta_r H°(1)$, was obtained from eleven experimental equillibrium constants measured by Holland (1) as corrected by Nernst (2). The second, $\Delta_r H°[2]$, was obtained from thirteen experimental equilibrium constants measured by Fischer and Jubermann (3).

For the same reaction, $PCl_3(g) + Cl_2(g) = PCl_5(g)$, a 3rd law calculation by Stevenson and Yost (4) gave a $\Delta H°(0\ K) = -21.320 \pm 0.107\ kcal\ mol^{-1}$. With a new assignment of fundamental frequencies Wilmshurst and Bernstein (5) reported a $\Delta E°(0\ K) = -20.525 \pm 0.16\ kcal\ mol^{-1}$.

The $\Delta_f H°(298.15\ K)$ values corresponding to these heats of reaction are:

$\Delta_f H°(298.15\ K)$	Source
$-82.9\ kcal\ mol^{-1}$	(4)
$-82.1\ kcal\ mol^{-1}$	(5)
$-81.9\ kcal\ mol^{-1}$	Calculated using Gibbs energy functions from JANAF Tables

Heat Capacity and Entropy

The fundamental vibrational frequencies were assigned by Wilmshurst and Bernstein (5) from their infrared and Raman spectral data, except the frequency, 176 cm^{-1}, which they calculated. Electron diffraction data of Rouault (6) and Sargent and Schomaker (7), show the free PCl_5 molecule to be a trigonal bipyramid of D_{3h} symmetry. The bond lengths were calculated from force constants and Badger's rule by Wilmshurst and Bernstein (5). Their values are in good agreement with the electron diffraction bond lengths of Rouault (6). The principal moments of inertia are $I_A = 73.5006 \times 10^{-39}$ and $I_B = I_C = 93.2215 \times 10^{-39}\ g\ cm^2$.

$S°(298.15\ K) = [221.75 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 489.7 \pm 1.5\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -858.98 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 35.146 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Gross et al. (3) measured the heat evolved in the reaction $Ta(cr) + 5/2\ Cl_2(g) = TaCl_5(cr)$. Using their data for 6 runs we calculate $\Delta_f H°(298.15\ K) = -205.6\ kcal\ mol^{-1}$ for $TaCl_5(cr)$. Gal'chenko et al. (4, 5) also determined the heat of reaction for the direct chlorination of Ta(15 runs involving 2 samples). They reported $\Delta_f H°(298.15\ K) = -205.05 \pm 0.18\ kcal\ mol^{-1}$. We adopt an intermediate value, $\Delta_f H°(298.15\ K) = -205.3 \pm 1.0\ kcal\ mol^{-1}$ ($-858.975 \pm 4.2\ kJ\ mol^{-1}$), based on these two studies (3, 4, 5).

Schafer and Kahlenberg (1) determined the heat of formation of $TaCl_5(cr)$ via calorimetric measurements of the heats of solution of Ta(cr) and $TaCl_5(cr)$ in hydrofluoric acid. Their procedure involved eight steps and resulted in $\Delta_f H°(298.15\ K) = -205.0 \pm 0.3\ kcal\ mol^{-1}$. This is in good agreement with our adopted value. In the case of $NbCl_5(cr)$ [$TaCl_5(cr)$] the $\Delta_f H°(298.15\ K)$ value derived from the data of Schafer and Kahlenberg (1, 2) is 0.6 kcal mol^{-1} [0.3 kcal mol^{-1}] more positive than that derived from the data of Gross et al. (3).

Heat Capacity and Entropy

The heat capacity for $TaCl_5(cr)$ is assumed to be the same as that for $NbCl_5(cr)$ (6). We adopt $S°(298.15\ K) = 53.0 \pm 1.5\ cal\ K^{-1}\ mol^{-1}$ in order to reproduce the sublimation and vaporization data. Schafer and Kahlenberg (1, 2) assumed a similar relationship based on a comparison with the corresponding values for the halides of Zr, Hf, and U.

Fusion Data

See the liquid table for details.

Sublimation Data

The enthalpy of sublimation is discussed in the $TaCl_5(g)$ table (6). Seven sublimation studies are analyzed and lead to a 3rd law result of $\Delta_{sub} H°(298.15\ K) = 22.5\ kcal\ mol^{-1}$.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

TANTALUM CHLORIDE ($TaCl_5$) *LIQUID* M_r = 358.2129

$S°(298.15\ K)$ = [268.135] J K^{-1} mol^{-1}

T_{fus} = 489.7 ± 1.5 K

$\Delta_f H°(298.15\ K)$ = [-834.347] kJ mol^{-1}

$\Delta_{fus}H°$ = 35.146 ± 2.1 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(TaCl_5, \ell, 298.15K)$ is calculated from that of $TaCl_5$(cr) by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(489.7 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The liquid phase heat capacity is assumed to be identical to that for $NbCl_5(\ell)$ (4). As in the case of $NbCl_5(\ell)$, there is a glass transition assumed at 350 K. S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°(298.15\ K)$

Fusion Data

We adopt T_{fus} = 478.9± 1.5 K (216.5°C) based on the work by Schafer and Pietruck (216.5°C, 1), Sheka et al. (216.5°C, 2), and Voitovich et al. (216.7°C, 3). Earlier reported melting points range between 204°C and 221°C and have been summarized by Schafer and Pietruck (1).

The adopted heat of fusion, $\Delta_{fus}H°$ = 8.4±0.5 kcal mol^{-1}, is based on the analysis of the S_2Cl_2-$TaCl_5$ system by Voitovich et al. (3). A similar study on the S_2Cl_2-$NbCl_5$ system (3) yielded a heat of melting for $NbCl_5$ which was within 0.063 kcal mol^{-1} of the result determined by drop calorimetry (4). The discussion of the molecular behavior of $NbCl_5(\ell)$ (4) is assumed to also apply to $TaCl_5$: that is, between the melting point and ~650 K, the substance changes from a dimeric solid to a monomeric liquid.

Vaporization Data

T_{vap} is calculated as that temperature for which $\Delta_r G°$ = 0 for the process $TaCl_5(\ell) \rightleftharpoons TaCl_5(g)$. $\Delta_{vap}H°$ is calculated as the difference between the $\Delta_f H°$ values for $TaCl_5(g)$ and $TaCl_5(\ell)$ at T_{vap}. Three vaporization studies are summarized in the $TaCl_5(g)$ table (4). Sheka et al. (2) studied the vapor-liquid equilibrium in the $TaCl_5$-$POCl_3$ system and measured a boiling point (at 760 mm) of 507.3 K for pure $TaCl_5$. The vaporization studies discussed in the $TaCl_5(g)$ table which included the boiling point yielded normal boiling points (p = 760 mm) in the range 506.0 - 506.9 K.

Enthalpy of Formation

The vapor pressures over $TaCl_5$(cr) and $TaCl_5$(ℓ) have been measured by eight investigators. The reported vapor pressures are corrected for vapor non-ideality by means of the equation $\Delta G°/T = R\ln p - Bp/T$. The Berthelot equation of state and critical constants T_c = 767 K and P_c = 43 atm. reported by Nisel'son et al. (6) are used to calculate B. The corrected vapor pressures are used to calculate $\Delta_r H°(298.15\ K)$ by both 2nd and 3rd law methods.

*One point rejected due to a statistical test.

The adopted value for $\Delta_f H°(298.15\ K)$ of $TaCl_5(g)$ is -182.8±2.0 kcal mol^{-1}. This value is calculated using the rounded mean 3rd law result for the seven sublimation studies, $\Delta_{sub} H°(298.15\ K)$ = 22.5 kcal mol^{-1}. The rounded mean 3rd law result for the three vaporization studies leads to a $\Delta_f H°(298.15\ K)$ value for the gas which is 0.1 kcal mol^{-1} more positive.

Heat Capacity and Entropy

$TaCl_5(g)$ was shown by Spiridonov and Romanov (15, 16), using electron diffraction techniques, to have a trigonal bipyramidal structure of D_{3h} symmetry: all the Ta-Cl bond lengths being equal within experimental uncertainty, Ta-Cl = 2.27±0.02 Å. Skinner and Sutton (10) earlier used electron diffraction techniques and had suggested the same structure although a square pyramidal structure was consistent with their experimental results. We adopt the results of Spiridonov and Romanov (15, 16). The principal moments of inertia are: $I_A = 91.0085 \times 10^{-39}$ and $I_B = I_C = 106.1766 \times 10^{-39}\ g\ cm^2$.

A normal coordinate treatment of $TaCl_5(g)$ in the Urey-Bradley force fields was performed by So (18) using the reported vibrational frequencies of Beattie and Ozin (17). This work by So (18) was intended to check the correctness of the reported fundamental frequencies and predict those frequencies which had not been observed (ν_3, ν_4, ν_5). Beattie and Ozin (17) had recorded the gas phase Raman spectra of $NbCl_5$, $NbBr_5$, $TaCl_5$, and $TaBr_5$. We adopt the results of So (18) which support the work of Beattie and Ozin (17).

There are many references in the literature to spectroscopic observations (IR and Raman) of $TaCl_5$ in the solid state and in organic solvents. Many problems arise in any attempt in relating the observed spectra. Tantalum pentachloride was shown to be dimeric in the solid phase (11), while there are indications that it is also dimeric in solution (12, 13, 14).

PREVIOUS: December 1974 (1 atm) CURRENT: December 1974 (1 bar)

$S°(298.15\ K) = [217.6]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 526\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -512.96 \pm 41.8\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 20.573 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WCl_5, cr, 298.15\ K) = -122.6\ kcal\ mol^{-1}$, is calculated from that of the gas less the heat of sublimation, $\Delta_{sub} H°(298.15\ K) = 24.0\ kcal\ mol^{-1}$. The latter is calculated by the 3rd law method from partial pressures of $WCl_5(g)$ derived from the total pressure data* of Shchukarev et al. (1). Dimer pressures, calculated from the same authors dimer-monomer dissociation data, are subtracted from the total pressures in order to obtain the monomer pressures. Analyses of the monomer pressures over both crystal and liquid give similar results and the average values for $\Delta_{sub} H°(298.15\ K)$ are 20.6 (2nd law) and 24.0 kcal mol^{-1} (3rd law) with a drift of about 7 cal $K^{-1}\ mol^{-1}$.

*Earlier data reported by Schukarev et al. (2), have been revised and are not used here.

Heat Capacity and Entropy

$C_p°(298) = 6.2\ cal\ K^{-1}\ mol^{-1}$ and $C_p°(526) = 7.25\ cal\ K^{-1}\ mol^{-1}$ are estimated using the method described by Kubaschewski and Evans (3). Between 298.15 and 528, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, $S°(298.15\ K) = 52\ cal\ K^{-1}\ mol^{-1}$, is listed by comparison with those of $WCl_2(cr)$, $WCl_4(cr)$ and $WCl_6(cr)$.

Fusion Data

The melting point was determined from vapor pressure data by Shchukarev et al. (1). The heat of melting is the difference at the melting point between the 2nd law enthalpies of vaporization and sublimation derived from total vapor pressure data of Schchukarev et al. (1).

Sublimation Data

See the ideal gas table for details.

TUNGSTEN PENTACHLORIDE (WCl_5) LIQUID M_r = 361.115

$S°(298.15\ K) = [248.500]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 526\ K$

$\Delta_f H°(298.15\ K) = -495.386\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 20.573 \pm 4.2\ kJ\ mol^{-1}$

Heat of Formation

The heat of formation $\Delta_f H°(WCl_5, \ell, 298.15\ K) = -118.4\ kcal\ mol^{-1}$, is calculated from that of $WCl_5(cr)$ by adding the heat of melting and the difference between H°(526;298.15) for the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be constant at 7.25 cal K^{-1} mol^{-1}.

The entropy of $WCl_5(\ell)$, S°(298.15 K) = 59.393 cal K^{-1} mol^{-1} is calculated in a manner analogous to that of the heat of formation.

Melting Data

See the crystal table for details.

Vaporization Data

The boiling point (f = 1 atm), 561.4 K, is calculated as the temperature at which the Gibbs energy of formation for both $WCl_5(\ell)$ and $WCl_5(g)$ are equal. The difference in the enthalpies of formation of $WCl_5(\ell)$ and $WCl_5(g)$ at the boiling point is the enthalpy of vaporization. Shchukarev et al. (1) revised their previous data (2) and derived the boiling point as 561.2 K from their vapor pressure measurements.

Bond Angles: Cl*-W-Cl* = [120]° Cl*-W-Cl** = [90]° Cl**-W-Cl** = [180]°

Product of the Moments of Inertia: $I_A I_B I_C$ = [9.98 x 10^{-112}] $g^3\ cm^6$

Enthalpy of Formation

The heat of formation, $\Delta_f H°(WCl_5, g, 298.15\ K) = -98.6\ kcal\ mol^{-1}$, is calculated from $\Delta_r H°(298.15\ K) = 19.4\ kcal\ mol^{-1}$ for $WCl_6(g) + WCl_5(g) + 1/2\ Cl_2(g)$. The value of $\Delta_r H°(298.15\ K)$ is calculated by the third law method from the equation for log Kp given by Shchukarev (1). The second law $\Delta_r H°(298.15\ K)$ is 24.6 kcal mol^{-1} and the third law drift is -8.5 cal $K^{-1}\ mol^{-1}$.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $MoCl_5$ determined by electron diffraction by Ewens and Lister (2). The bond distance is estimated to be the same as that in $WCl_6(g)$. The three principal moments of inertia are: $I_A = 90.2084 \times 10^{-39}$ and $I_B = I_C = 105.2432 \times 10^{-39}\ g\ cm^2$.

All vibrational frequencies are estimated from those of $SbCl_5$, PCl_5, $NbCl_5$ and $TaCl_5$ obtained from infrared and Raman spectra by Carlson (3).

If it is considered that the metal atoms are effectively ionized, then the W^{5+} will have a single d electron in a field of chloride ions. The electronic splitting would be roughly the inverse of that in $CuCl_2(g)$ as given by DeKock and Gruen (4), where Cu has a d^9 configuration. By analogy with the splitting in $CuCl_2$, the low lying electronic levels are estimated to be 7000 cm^{-1}, both doublets.

Bond Distances: Fe-Cl = 2.11 ± 0.03 Å $Fe-Cl_{bridge}$ = 2.28 ± 0.03 Å
Bond Angles: Cl-Fe-Cl = 128 ± 3° $Cl_{bridge}-Fe-Cl_{bridge}$ = 92 ± 3°
Product of the Moments of Inertia: $I_A I_B I_C$ = 7.05018 x 10^{-111} g^3 cm^6

Enthalpy of Formation

The vaporization of $FeCl_3$(cr) is complex. It involves three possible chemical reactions, i.e. (1) $2FeCl_3(cr) = Fe_2Cl_6(g)$; (2) $FeCl_3(cr) = FeCl_3(g)$; and (3) $2FeCl_3(cr) = 2FeCl_2(cr) + Cl_2(g)$. Although these equilibria have been studied previously by many investigators, a review of their reported data reveals inconsistencies and errors. At room temperature the main vapor species present above $FeCl_3$(cr) is Fe_2Cl_6(g), a dimer of $FeCl_3$(g). As temperature increases, the dimer gradually decomposes into monomers ($FeCl_3$, g). Simultaneously, part of $FeCl_3$(cr) also decomposes into $FeCl_2$(cr) and Cl_2(g). Therefore in order to obtain the partial pressure of Fe_2Cl(g), the partial pressures of other vapor species, e.g. Cl_2(g) and $FeCl_3$(g), must be known and deducted from the observed total pressures. However, only few investigators made such corrections. The total pressures above $FeCl_3$(cr), at 500-600 K, have been determined by Maier (1) and Johnstone et al. (2), respectively. The partial pressures of Fe_2Cl_6(g) were evaluated by the subtraction of the calculated equilibrium pressures of Cl_2(g), obtained from reaction (3), from the reported total pressures. The partial pressures of $FeCl_3$(g) were found to be insignificant at these temperatures. Using the partial pressures obtained for Fe_2Cl_6(g), the enthalpy change $\Delta_r H°(298.15\ K)$ of reaction (1) was derived by both the second and third law methods. Then the value of $\Delta_f H°(Fe_2Cl_6, g, 298.15\ K)$ was calculated. The results are given in this table.

Wilson and Gregory (3) have investigated the vaporization and thermal decomposition equilibria of $FeCl_3$(cr) by gas saturation flow and diaphragm gage techniques. Using the partial pressures for Fe_2Cl_6(g), calculated from an equation, the values of $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(298.15\ K)$ were also evaluated and listed in the table. Based on the total pressures measured by Stirnemann (4) and Sano (5), the equations for the pressures of Fe_2Cl_6(g) and Cl_2(g) in equilibrium with $FeCl_3$(cr) and $FeCl_2$(cr) as a function of temperature were reported by Wilson and Gregory (3). The corresponding values of $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(298.15\ K)$ were hence calculated. A brief summary and discussion of results of some other previous investigators were also given in the same report.

Source	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	$\Delta_f H°(298.15\ K)$* kcal mol^{-1}
Maier (1)	489.6-591.5	32.18±0.40	34.67	-156.25±0.50
Johnstone, et al. (2)	505.2-562.2	34.81±0.49	34.50	-156.42±0.50
Wilson and Gregory (3)	463.4-577.2	34.46	34.45	-156.47±0.40
Stirnemann (4)	526.2-574.2	35.04	34.49	-156.43±0.50
Sano (5)	513.2-569.2	30.67	34.76	-156.16±0.50

The value of $\Delta_f H°(298.15\ K)$ for Fe_2Cl_6(g) is selected as -156.4±2.0 kcal mol^{-1}.

Heat Capacity and Entropy

The molecular structure, bond distances and angles were obtained from Zasorin et al. (6). The vibrational frequencies were estimated by comparison with those for Al_2Cl_6(g) such that the values of ΔH° derived from the equilibrium data by the 2nd and 3rd law methods are in reasonable agreement. The principal moments of inertia are: I_A = 116.3664 x 10^{-39}, I_B = 194.7424 x 10^{-39} and I_C = 311.1088 x 10^{-37} g cm^2.

MOLYBDENUM CHLORIDE ($MoCl_6$) CRYSTAL M_r = 308.658

$S°(298.15\ K) = [255.2 \pm 16.7]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-523 \pm 42]\ kJ\ mol^{-1}$

Enthalpy of Formation

Novikov and Galitskii (1), assumed that the equilibrium $MoCl_6(cr) = MoCl_5(g) + 1/2\ Cl_2(g)$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, $\Delta_r H°(T) = 4$ kcal mol^{-1} and $\Delta_r ST) = 8$ cal K^{-1} mol^{-1}, of the equilibrium $MoCl_6(cr) = MoCl_5(cr) + 1/2\ Cl_2(g)$, from which they obtained the $\Delta_f H°(MoCl_6, cr, 298.15\ K) = -125$ kcal mol^{-1}.

Heat Capacity and Entropy

The adopted heat capacity is the same as that of $WCl_6(a, cr)$, since the heat capacities of W and Mo are almost the same. The entropy is estimated from that of $MoCl_5(cr)$ by the addition of 4 cal K^{-1} mol^{-1} due to one extra chlorine atom in the molecule.

Vaporization Data

The sublimation point is calculated from the Gibbs energy crossover between crystal and gas. However, it should be noted that $MoCl_6(cr)$ is unstable with respect to $MoCl_5(cr)$ at all temperatures and thus sublimation could occur only under an atmosphere of Cl_2.

Ground State Quantum Weight: [1] $\sigma = 24$

Point Group: O_h

Bond Distance: Mo-Cl = [2.26] Å

Bond Angle: Cl-Mo-Cl = [90]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.74003 \times 10^{-111}]\ g^3\ cm^6$

Enthalpy of Formation

Novikov and Galitskii (1), assumed that the equilibrium $MoCl_6(cr) = MoCl_5(g) + 1/2\ Cl_2(g)$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, $\Delta_r H°(T) = 2.5\ kcal\ mol^{-1}$ and $\Delta_r S° = 10\ cal\ K^{-1}\ mol^{-1}$ of the equilibrium $MoCl_6(g) = MoCl_5(g) + 1/2\ Cl_2(g)$, from which they obtained the $\Delta_f H°(MoCl_6, g, 298.15\ K) = -105\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of MoF_6 and WF_6, given by Nakamoto (2), and WCl_6 given by Evans and Lo (3).

Structure, bond distance and bond angle are estimated to be the same as those of WCl_6. The principal moments of inertia are: $I_A = I_B = I_C = 120.2779 \times 10^{-39}\ g\ cm^2$.

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

$S°(298.15\ K) = [238.488]\ J\ K^{-1}\ mol^{-1}$
$T_{trs}\ (\alpha_1 + \alpha_2) = 450 \pm 10\ K$
$T_{trs}\ (\alpha_2 + \beta) = 503 \pm 3\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -593.71 \pm 25.1\ kJ\ mol^{-1}$
$\Delta_{trs} H°\ (\alpha_1 + \alpha_2) = [4.2]\ kJ\ mol^{-1}$
$\Delta_{trs} H°\ (\alpha_2 + \beta) = 15.774\ kJ\ mol^{-1}$

Enthalpy of Formation

Shchukarev et al. (1) have measured calorimetrically the heat of solution of WCl_6(cr) and also of H_2WO_4(cr) in a 12% solution of NaOH as -188.0±0.3 and -13.6±0.11 kcal mol^{-1}, respectively. Based on these data and a heat of dilution value for Na_2WO_4 which is essentially zero, we obtain $\Delta_r H°(298.15\ K) = -174.4 \pm 0.3$ kcal mol^{-1} for WCl_6(cr) + 6 NaOH(aq, 16.3 H_2O) + H_2WO_4(cr) + 6 NaCl(aq, 22000 H_2O) + 2 $H_2O(\ell)$. This reaction gives $\Delta_f H°(WCl_6, cr, 298.15\ K) = -141.9 \pm 6$ kcal mol^{-1}, using a revised $\Delta_f H°(H_2WO_4, cr, 298.15\ K) = 270.5$ kcal mol^{-1}, and other auxiliary data from *JANAF Tables and from* Parker (2). *The authors have suggested a possible* uncertainty of the order of 5 kcal mol^{-1} due to the slowness of the dissolution of WCl_6(cr).

Heat Capacity and Entropy

Welty (5) has measured the enthalpy changes for $WCl_6(\alpha, cr)$ in the temperature range from 406 to 502.4 K by drop calorimetry. Few points were measured in the region of the $\alpha_1 + \alpha_2$ transition and no attempt was made to investigate the phase present at the conclusion of the drop. Thus, these data appear to be inadequate to define the heat capacities of the α_1 and α_2 phase. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy, $S°(298.15\ K) = 57.0$ cal $K^{-1}\ mol^{-1}$, is calculated from that of the gas using $\Delta S°(298.15\ K) = 43.155$ cal $K^{-1}\ mol^{-1}$ from the vaporization and sublimation data given in the WCl_6(g) table (December 31, 1966).

Transition Data

Transition temperatures and heats of transition have been reported by the following investigators, and their results are summarized as follows:

		$\alpha_1 + \alpha_2$ Transition		$\alpha_2 + \beta$ Transition	
Source	Method	T/K	$\Delta_{trs}H°$ kcal mol^{-1}	T/K	$\Delta_{trs}H°$ kcal mol^{-1}
Ketelaar et. al (3)	Vapor pressure	441	--	500	3.4
Stevenson (4)	Cooling curve	458	--	503	--
	Vapor pressure	--	--	503	1.9
Welty (5)	Drop calorimetric	--	--	504	3.4
Shchukarev et al. (6)	Vapor pressure	--	--	504	3.4
Dobortin	Approximate calorimetric	--	--	493 ± 10	5.5

The adopted $\Delta_f H°(450\ K)$ $(\alpha_1 + \alpha_2)$ and $\Delta_f H°(503\ K)$ $(\alpha_2 + \beta)$ are calculated as 1.0 and 3.77 kcal mol^{-1}, respectively, based on the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to α_1 phase as the final state, although no experimental evidence for this is given.

Fusion Data

See the β-crystal table for details.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: December 1962 CURRENT: December 1966

$S°(298.15\ K) = [280.604]\ J\ K^{-1}\ mol^{-1}$
$T_{trs}\ (\alpha_2 \rightarrow \beta) = 503 \pm 3\ K$
$T_{fus} = 555 \pm 2\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = [-572.877]\ kJ\ mol^{-1}$
$\Delta_{trs} H°(\alpha_2 \rightarrow \beta) = [15.774]\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [6.694]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WCl_6, \beta, cr, 298.15\ K) = -136.921\ kcal\ mol^{-1}$, is calculated from that of $WCl_6(\alpha,cr)$ by adding the heat of $\alpha_2 \rightarrow \beta$ transition and the difference between $H°(593;298.15)$ for $WCl_6(\alpha,cr)$ and $WCl_6(\beta,cr)$.

Heat Capacity and Entropy

Welty (1) has measured the enthalpy changes for $WCl_6(\beta,cr)$ in the temperature range from 508 to 553 K by drop calorimetry. Because of the short temperature range, poor distribution of pints and lack of identification of the phase present at the conclusion of each drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are consistent with the enthalpy data within their probable uncertainty.

The entropy of $WCl_6(\beta,cr)$, $S°(298.15\ K) = 67.066\ cal\ K^{-1}\ mol^{-1}$ is calculated in a manner analogous to that of the heat of formation.

Transition Data

See the α-crystal table for details.

Fusion Data

Melting point and heat of melting have been reported by the following investigators, and their results are summarized as follows:

Source	Method	T_{fus}/K	$\Delta_{fus}H°$(kcal mol^{-1})
Ketelaar et al. (2)	Vapor pressure	557	2.3
Stevenson (3)	Cooling curve	555	-
	Vapor Pressure	555	1.5
Welty (1)	Drop calorimetric	556	1.6
Shchukarev et al. (4)	Vapor pressure	564	2.0
Dobrotin et al. (5)	Approximate calorimetric	545 ± 12	4.2

The adopted heat of melting, $\Delta_f H°(555\ K) = 1.6\ kcal\ mol^{-1}$, is calculated from the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to α_1 phase as the final state, although no experimental evidence for this is available.

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ is calculated as the difference between $\Delta_f H°(298.15\ K)$ for $WCl_6(\beta,cr)$ and $WCl_6(g)$.

TUNGSTEN CHLORIDE (WCl_6) LIQUID M_r = 396.568

$S°(298.15\ K)$ = [284.868] J K^{-1} mol^{-1}

T_{fus} = 555 ± 2 K

$\Delta_f H°(298.15\ K)$ = [-569.405] kJ mol^{-1}

$\Delta_{fus}H°$ = 6.694 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(WCl_6, \ell, 298.15\ K)$ is calculated from that of $WCl_6(\beta, cr)$ by adding the enthalpy of fusion and the difference in enthalpy, $H°(555\ K)-H°(298.15\ K)$, between the β- crystal and liquid.

Heat Capacity and Entropy

Welty (1), has measured the enthalpy changes for $WCl_6(\ell)$ in the temperature range from 560 to 603 K by drop calorimetry. Since the temperature range was very short and no attempt was made to investigate the phase present at the conclusion of the drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

$S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the β-crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which the Gibbs energies of formation for both $WCl_6(\ell)$ and $WCl_6(g)$ are equal. The difference in the enthalpies of formation of $WCl_6(\ell)$ and $WCl_6(g)$ at T_{vap} is the enthalpy of vaporization.

Ketelaar, et al. (2), have determined the boiling point and the heat of vaporization as 609.7 K and 15.24 kcal mol^{-1}, respectively, from vapor pressure measurements. Shchukarev and Suvorov (3, 4) revised their previous data and gave the boiling point and the heat of vaporization as 616.2 K and 14.7 kcal mol^{-1}, respectively, from their vapor pressure measurements.

See the ideal gas table for additional information.

Bond Angle: Cl-W-Cl = 90°
Product of the Moments of Inertia: $I_A I_B I_C = 1.74003 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation of $WCl_6(g)$, $\Delta_f H°(298.15\ K) = -118.0\ kcal\ mol^{-1}$, is calculated from that of the crystal plus the adopted heat of sublimation, $\Delta_{sub}H°(298.15\ K) = 23.9\ kcal\ mol^{-1}$ for $WCl_6(\alpha, cr) \rightarrow WCl_6(g)$. The latter was obtained from third law analysis of the vapor pressure data (1, 2, 3, 4), using all JANAF functions (Dec. 31, 1966).

Ketelaar (3) et al.	α, cr	425 - 500	21	23.1 ± 0.1	23.94	1.7 ± 0.4	-117.96
	β*, cr	504 - 554	21	24.4 ± 0.1	23.91	-0.8 ± 0.1	-117.99
	l*	523 - 635	21	24.4 ± 0.1	23.85	-1.0 ± 0.1	-118.05
Vernon (4)	α, cr	298 - 423	4	16.1 ± 4.1	21.02	10.8 ± 12.8	-120.88

Vernon (4) has also determined the equilibrium constants in the temperature range from 1360 to 1600 K for the decomposition of $WCl_6(g)$ to W(cr) and $Cl_2(g)$ by reaction of the sample with a hot tungsten filament in a vacuum bulb. Using the reported equilibrium constants, the heat of formation of $WCl_6(g)$ at 298 K is calculated by the second and third law method as -131.8 ± 2.9 kcal mol^{-1} and -135.2 kcal mol^{-1}, respectively. The third law drift is 2.4 ± 1.9 cal K^{-1} mol^{-1}. Unfortunately the reported equilibrium constants may be seriously in error since atomic chlorine is the main species at the pressure and temperature studied.

* Enthalpy changes are converted to $\Delta_{sub}H°(298.15\ K)$ for $WCl_6(\alpha, cr) \rightarrow WCl_6(g)$.
** Vapor presssure equations for the crystal (α, β) and the liquid to gas are given.

Heat Capacity and Entropy

Ewens and Lister (5) have determined the octahedral structure for $WCl_6(g)$ by electron diffraction and found the bond length to be 2.26 Å.

The vibrational frequency of ν_3, 375 cm^{-1}, was observed in the infrared spectra by Evans (6). The values of ν_1, ν_2, and ν_5 (360, 340 and 180 cm^{-1}, respectively) are estimated based on those of the aqueous ion $PtCl_6^{2-}$ reported by Woodward and Creighton (7). The values of ν_4 and ν_6 (140 and 120 cm^{-1}, respectively) are estimated by comparison with those of $WF_6(g)$.

The principal moments of inertia are: $I_A = I_B = I_C = 120.2779 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: [3] σ = [4]

Point Group: [D_{2h}]

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl*-W-Cl* = [90]° $W-Cl^*_{bridge}-W$ = [90]°
Cl**-W-Cl** = [180]° Cl*-W-Cl** = [90]°
* = Equatorial ** = Axial

Product of the Moments of Inertia: $I_A I_B I_C = [6.64026 \times 10^{-110}]\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(W_2Cl_{10}, g, 298.15\ K) = -207.6\ kcal\ mol^{-1}$, is calculated from $\Delta_r H°(298.15\ K) = 10.4\ kcal\ mol^{-1}$ for $W_2Cl_{10}(g) = 2\ WCl_5(g)$, using all JANAF functions (Dec. 31, 1966). The value of $\Delta_r H°(298.15\ K)$ is obtained from third law *analysis of the partial pressures of* $WCl_5(g)$ *and* $W_2Cl_{10}(g)$ *derived from PVT data determined* by Shchukarev *et al.* (1). The second law $\Delta_r H°(298.15\ K)$ is $10.4 \pm 0.3\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The molecular configuration is estimated by analogy with that of Mo_2Cl_{10} reported by Sands and Zalkin (2). Chlorine atoms are placed octahedrally around two tungsten atoms and these two octahedra share one common edge with six chlorine and two tungsten atoms in a plane. The bond length is estimated to be the same as that in $WCl_6(g)$. The principal moments of inertia are: $I_A = 210.4863 \times 10^{-39}$, $I_B = 546.8356 \times 10^{-39}$, and $I_C = 576.9051 \times 10^{-39}\ g\ cm^2$.

All vibrational frequencies are estimated based on those of WCl_5, $(AlCl_3)_2$ and Cs_2Cl_2, such that $S°(W_2Cl_{10}, g, 607\ K) = 216.65\ cal\ K^{-1}\ mol^{-1}$. This entropy is derived from $\Delta S°(607\ K) = 19.92 \pm 0.5\ cal\ K^{-1}\ mol^{-1}$ for $W_2Cl_{10}(g) = 2WCl_5(g)$, obtained by 2nd law analysis of the data of Shchukarev et al. (1). The frequencies are not in point group order.

Cobalt (Co) Co_1(ref)

$S°(298.15\ K) = 30.067 \pm 0.10\ J\ K^{-1}\ mol^{-1}$
$T_{trs}(\alpha + \beta) = 700\ K$
$T_{fus} = 923 \pm 1\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{tr} H° = 0.452\ kJ\ mol^{-1}$
$\Delta_{fus} H°(923\ K) = 16.192 \pm 0.25\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity of Co(cr) is adopted from Hultgren et al. (1). Their selected values are based on the data from nineteen investigations. The entropy values are based on $S°(1\ K) = 0.0011\ cal\ K^{-1}\ mol^{-1}$. The heat capacity has a maximum value of 13.14 $cal\ K^{-1}\ mol^{-1}$ at the Curie point (1394 K).

Transition Data

The exact nature of the α(hcp) - β(fcc) transition is yet to be clearly elucidated. Three investigations (2, 3, 4) indicate that it is not a simple time- and temperature-dependent phenomenon. Crystalline cobalt exists as pure β-phase above 700 K whereas mixtures of alpha and beta cobalt commonly coexist in varying proportions below this temperature. The values of T_{trs} and $\Delta_{trs}H°$ are those selected by Hultgren et al. (1).

Fusion Data

The temperature and enthalpy of melting are those selected by Hultgren et al. (1).

Sublimation Data

The enthalpy of sublimation is calculated from the data of Edwards et al. (5). See the ideal gas table for details.

PREVIOUS: CURRENT: September 1967

COBALT (Co) LIQUID A_r = 58.9332

$S°(298.15\ K)$ = [41.000] J K^{-1} mol^{-1}

T_{fus} = 1768 K

$\Delta_f H°(298.15\ K)$ = [18.004] kJ mol^{-1}

$\Delta_{fus} H°$ = 16.192 ± 0.25 kJ mol^{-1}

Enthalpy of Formation

The enthalpy of formation of Co(ℓ) is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1768K) -H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of Co(ℓ) selected by Hultgren et al. (1) is used at temperatures above 1789 K. The heat capacities at temperatures below the melting point are estimated by assuming a glass transition at 1100 K and heat capacities similar to those of the crystal below 1100 K.

Fusion Data

See the crystal table for details.

Vaporization Data

The boiling point is calculated from the adopted thermodynamic functions and the chosen enthalpy of sublimation at 298.15 K so that the Gibbs energy functions calculated by integration of the crystal liquid data and by statistical methods from the gas phase are equal at the boiling point.

Enthalpy of Formation

The enthalpy of formation is the enthalpy of sublimation at 298.15 K. The adopted value is that reported by Edwards et al. (1). Their value is used because their vapor pressure measurements for Fe (1) and Cu (2) have proved to be very reliable. The results obtained by Vintaikin and Tomash (3) are rejected because their vapor pressure data for Fe (4) resulted in a value for the enthalpy of sublimation which was higher than the accepted value [see JANAF Fe(g) Table for details]. The remaining vapor pressure data are rejected either because the drift was too large or because there were not enough points. Second and third law analyses of the available vapor pressure data gave the following results, with reaction A corresponding to Co(c) = Co(g) and reaction B corresponding to Co(ℓ) = Co(g).

Source	Reaction	Method	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal $K^{-1}mol^{-1}$	$\Delta_f H°(298.15K)$ kcal mol^{-1}
Edwards (1)	A	Langmuir	9	1363-1522	101.0 ± 1.0	101.54	±0.4 ± 0.7	101.54

*One point rejected due to failure of a statistical test.

Heat Capacity and Entropy

The electronic levels are taken from Moore (10). All observed levels were used but only the first few levels are listed above.

Unobserved levels below 20,000 cm^{-1} are estimated.

Enthalpy of Formation

$\Delta_f H°(Co^+, g, 0\ K)$ is calculated from $\Delta_f H°(Co, g, 0\ K)$ (1) using the spectroscopic value of IP(Co) = 63430 ± 10 cm^{-1} (758.79 ± 0.12 $kJ\ mol^{-1}$) from Sugar and Corliss (2). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Co^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Co, g, 0\ K)$ by using IP(Co) with JANAF (1) enthalpies, H°(0 K) − H°(298.15 K), *for Co(g), $Co^+(g)$, and $e^-(g)$. $\Delta_f H°(Co + Co^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of* these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by −6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Sugar and Corliss (2), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first excited state, the highest observed excited state, and the ionization potential for $Co^+(g)$, all levels listed by Sugar and Corliss (2), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate *that for $Co^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=3), the cut-off procedure, and* the inclusion of n=7 levels up to 1000 K; the Gibbs energy function showing variations of 0.05% at this temperature. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>7), and use of different fill and cut-off procedures (6).

COBALT, ION (Co^-) IDEAL GAS M_r = 58.93375

EA(Co, g) = 0.661 ± 0.010 eV

$S°(298.15\ K) = 178.412 \pm 0.005\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 361.31 \pm 4.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [356.649]\ kJ\ mol^{-1}$

Electonic Levels and Quantum Weights

State	ϵ_i, cm^{-1}	g_i
$^3F_4$	0.0	9
$^3F_3$	910	7
$^3F_2$	1560	5

Enthalpy of Formation

$\Delta_f H°(Co^-, g, 0\ K)$ is calculated from $\Delta_f H°(Co, g\ 0\ K)$ (1) using the adopted electron affinity of EA(Co) = 0.661 ± 0.010 eV (63.776 ± 0.965 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Co^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Co^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Co, g, 0\ K)$ by using EA(Co) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Co^-(g)$, Co(g), and $e^-(g)$. $\Delta_r H°(Co^- + Co + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state and fine-structure separations for $Co^-(g)$ have been experimentally determined by Corderman et al. (3). Lacking any experimental evidence as to the existence of stable excited states, we assume no stable excited states exist.

PREVIOUS: CURRENT: June 1984 (1 bar)

$S°(298.15\ K) = 82.026 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1400 \pm 7.0\ K$

$\Delta_f H°(0\ K) = -670.4 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -671.53 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 58.819 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

Heus and Egan (1) measured the emf of a solid state galvanic cell which involved the reactions: Al(cr) + 3/2 CoF_2(cr) + AlF_3(cr) + 3/2 Co(cr), E(873 K) = 1.611 volts; Mg(cr) + CoF_2(cr) + MgF_2(cr) + Co(cr), E(873 K) = 2.231 volts. Combining these results with auxiliary thermodynamic data (2) for the reactants and products, we derive $\Delta_f H°(CoF_2, cr, 298.15\ K) = -160.2$ and $-159.95\ kcal\ mol^{-1}$.

Several equilibrium studies (3, 4, 5) involving CoF_2(cr) have been reported in the literature. 2nd and 3rd law analyses of these equilibrium data are summarized below, auxiliary data for CoO(cr) and $CoCl_2$(cr) are from (6).

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	*$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(3)	$CoF_2(cr) + 2HCl(g) \rightleftarrows CoCl_2(cr) + 2HF(g)$	588-805	3	4.1	1.75±0.4	-1.7±0.1	-162.6±2.0
(4)	$CoF_2(cr) + H_2(g) \rightleftarrows Co(cr) + 2HF(g)$	673-873	3	35.2	31.5±1.0	-4.2±3.5	-161.8±2.0
(5)	$CoF_2(cr) + H_2O(g) \rightleftarrows CoO(cr) + 2HF(g)$	773-1023	5	30.2	31.1±0.2	0.9±0.3	-160.45±1.0

*3rd law values except for the first reaction.

We note that Heus and Egan (1), in the same paper, measured $\Delta_f H°(AlF_3, cr, 298.15\ K) = -360.2\ kcal\ mol^{-1}$ which is in excellent agreement with the JANAF value (2). Domange (5) also measured similar equilibria for MgF_2 and CaF_2, which were very consistent with the JANAF enthalpies of formation (2). Jellinek and Rudat (4) reported similar equilibria for PbF_2(cr), which show excellent consistency with the JANAF enthalpy of formation (2). Thus, it is apparent that these three sets are probably quite reliable, and we adopt $\Delta_f H°(CoF_2, cr, 298.15\ K) = -160.5 \pm 1\ kcal\ mol^{-1}$ ($-671.532 \pm 4.2\ kJ\ mol^{-1}$).

Heat Capacity and Entropy

Catalano and Stout (7) measured low temperature heat capacities in the temperature range 10 to 300 K. Heat capacity data above 300 K are calculated from the high temperature (468-1400 K) enthalpy data of Binford et al. (8). Both sets of data were smoothed by computer and joined at 298.15 K.

The value of S°(298.15 K) is obtained from the low temperature heat capacity data of Catalano and Stout (7) and is based on $S°(10\ K) = 0.013\ cal\ K^{-1}\ mol^{-1}$ ($0.05439\ J\ K^{-1}\ mol^{-1}$).

Fusion Data

See the liquid table for details.

Sublimation Data

Kana'an et al. (9) made sublimation studies of CoF_2 using Knudsen and Langmuir techniques over the temperature range 972-1241 K. 2nd and 3rd law analyses of these sublimation pressures are summarized below.

Method	T/K	Data Points	$\Delta_{sub} H°(298.15\ K)$ kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
Knudsen	1058-1242	17	75.0	75.1±0.1	0.1±0.2
Langmuir	972-1032	8	72.8	75.5±0.2	2.6±1.4

The selected value is $\Delta_{sub} H°(298.15\ K) = 75.3 \pm 3.0\ kcal\ mol^{-1}$ ($315.055 \pm 12.6\ kJ\ mol^{-1}$).

PREVIOUS: CURRENT: June 1970

$S°(298.15\ K) = [86.238]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1400 \pm 7.0\ K$

$\Delta_f H°(298.15\ K) = [-637.691]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 58.819 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(CoF_2, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(CoF_2, cr, 298.15\ K)$ by adding the enthalpy of fusion and the difference in enthalpy, H°(1400 K) - H°(298.15), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of liquid CoF_2 is estimated by comparison with those for $FeCl_2(\ell)$, $MgF_2(\ell)$, and $PbF_2(\ell)$ and is assumed constant in the temperature range 298 - 3000 K. Binford et al. (1) reported Cp = 30.3 cal $K^{-1}\ mol^{-1}$ for liquid CoF_2 at 1444 K. This value is based on only two enthalpy points near the melting point and appears high in comparison with heat capacities for other liquid metal dihalides. Therefore, the value is not adopted.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} = 1400 K is from the high temperature enthalpy studies of Binford et al. (1). $\Delta_{fus} H°$ is calculated from their enthalpy data. Premelting of the sample is assumed to be responsible for the rapid rise in enthalpy near the melting point. This enthalpy is included in $\Delta_{fus} H°$.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change for the process $CoF_2(\ell) \rightarrow CoF_2(g)$ equals zero. The difference between the enthalpy of formation of the gas and liquid at T_{vap} is $\Delta_{vap} H°$.

COBALT FLUORIDE (CoF_2) CRYSTAL-LIQUID M_r = 96.930006

0 to 1400 K crystal
above 1400 K liquid

Refer to the individual tables for details.

Point Group: C_{2v} $\sigma = 2$
Bond Distance: Co-F = [1.72] Å
Bond Angle: F-Co-F = [165]°
Product of Moments of Inertia: $I_A I_B I_C = 6.57815 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(CoF_2, g, 298.15\ K) = -85.2 \pm 3.0$ kcal mol^{-1} (-355.477 ± 12.6 kJ mol^{-1}), is calculated from the enthalpy of formation of the crystal, $\Delta_f H°(CoF_2, cr, 298.15\ K) = -160.5 \pm 4.0$ kcal mol^{-1}, and the enthalpy of sublimation, $\Delta_{sub} H°(298.15\ K) = 75.3 \pm 3.0$ kcal mol^{-1}. The sublimation value is determined from a 3rd law analysis of the vapor pressure data for CoF_2 reported by Kana'an et al. (1). *See the crystal table for details.*

Heat Capacity and Entropy

Buchler et al. (2) investigated the deflection of a molecular beam of $CoF_2(g)$ by an electric field and found that within the sensitivity of the apparatus the molecule was nonpolar and consequently possessed a linear structure. Hastie et al. (3) recently *investigated the infrared absorption spectra of several transition metal difluorides through the use of matrix isolation* techniques. Isoptopic shift measurements for matrix isolated NiF_2, ZnF_2, and CuF_2 in neon and argon indicated that these species were slightly bent. Based upon these results, the authors estiamted the F-Co-F angle as 165°. This value is adopted here. The bond length was estimated by Brewer et al. (4). The principal moments of inertia are: $I_A = 0.1934 \times 10^{-39}$, $I_B = 18.3484 \times 10^{-39}$, and $I_C = 18.5417 \times 10^{-39}$ g cm^2.

Hastie et al. (3) isolated CoF_2 in neon and argon matrices and observed the ν_3 fundamental at 762 cm^{-1}. They also calculated ν_1 = 600 cm^{-1} by a valence force field method and estimated ν_2 as 151 cm^{-1} by applying the variation in the frequencies for the chlorides of Co, Ni, Cu, and Zn to the fluorides. The electronic levels and quantum weights are estimated by comparison with the electronic energy levels for $Co^{++}(g)$ ion (5) and those for $CoCl_2(g)$ observed by Hougen et al. (6).

$S°(298.15\ K) = [94.6 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [1200 \pm 200]\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -790.36 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

Fowler et al. (1) determined calorimetrically the enthalpy of fluorination of crystalline CoF_2 at 473.15 K. For the reaction $2\ CoF_2(cr) + F_2(g) \rightarrow 2\ CoF_3(cr)$ they reported $\Delta_r H°(473.15\ K) = -52.0 \pm 3.0$ kcal mol^{-1} which yields $\Delta_r H°(298.15\ K) = -52.4 \pm 3.0$ kcal mol^{-1} based upon our functions for CoF_2(cr) and CoF_3(cr). Combining this result with the enthalpy of formation of CoF_2(cr) (2), we derive $\Delta_f H°(CoF_3, cr, 298.15\ K) = -186.7 \pm 3.0$ kcal mol^{-1}.

Jessup et al. (3) investigated calorimetrically this same fluorination reaction and reported $\Delta_r H°(523.15\ K) = -56.1 \pm 2.0$ kcal mol^{-1}. This result leads to $\Delta_f H°(CoF_3, cr, 298.15\ K) = -188.8 \pm 2.0$ kcal mol^{-1}. In the same investigation Jessup et al. (3) reported $\Delta_r H°(608\ K) = -74.0 \pm 4.0$ kcal mol^{-1} for the reduction reaction $2\ CoF_3(cr) + H_2(g) \rightarrow 2\ CoF_2(cr) + 2\ HF(g)$. Corrected to 298.15 K we calculate $\Delta_r H°(298.15\ K) = -73.3 \pm 4.0$ kcal mol^{-1}. Combining this result with enthalpy of formation data for CoF_2(cr)(2). and HF(g) (4), we derive $\Delta_f H°(CoF_3, cr, 298.15\ K) = -189.0 \pm 4.0$ kcal mol^{-1}. We note that the addition of these two results by Jessup et al. (3) leads to $\Delta_r H°(298.15\ K) = -129.9 \pm 6.0$ kcal mol^{-1} for the reaction $H_2(g) + F_2(g) \rightarrow 2\ HF(g)$ which is quite consistent with the result -130.28 ± 0.4 kcal mol^{-1} calculated from the selected value for the enthalpy of formation of HF(g) (4). Thus, it is apparent that these two results are probably quite reliable, and we adopted $\Delta_f H°(CoF_3, cr, 298.15\ K) = -188.9 \pm 3.0$ kcal mol^{-1} (-790.358 ± 12.6 kJ mol^{-1}).

Jellinek and Koop (5) reported equilibrium constants for the reduction reaction given above in the temperature range 470-595 K. 2nd and 3rd law analyses of these equilibrium data give $\Delta_r H°(298.15\ K)$ of 31.7 and 29.3 ± 0.6 kcal mol^{-1}, respectively; the drift is -4.7 ± 1.5 cal K^{-1} mol^{-1}. These values are in considerable disagreement with the calorimetric value of -73.3 ± 4.0 kcal mol^{-1} given by Jessup et al. [3], and no weight is given to these equilibrium data.

Heat Capacity and Entropy

Heat capacity data for CoF_3(cr) are estimated by comparison with those for FeF_2(cr), FeF_3(cr), TiF_3(cr), and CoF_2(cr). $S°(298.15\ K)$ is estimated to be 22.6 cal K^{-1} mol^{-1} (94.5584 J K^{-1} mol^{-1}) from the ionic entropy contributions given by Kubaschewski, Evans, and Alcock (6). We note that this method leads to $S°(298.15\ K) = 19.4$ cal K^{-1} mol^{-1} for CoF_2(cr) which is in good agreement with the experimental value of 19.60 ± 0.10 cal K^{-1} mol^{-1} (2).

Fusion Data

T_{fus} is estimated by comparison with those for other transition metal halides. We note that Ruff and Ascher [7] reported CoF_3(cr) being thermally unstable around 900 K, while Stewart (8) recently showed that CoF_2(cr) was formed by hydrolytic reactions and not by thermal decomposition. The derived $\Delta_f G°$ values for CoF_3(cr) indicate that it is thermodynamically more stable than CoF_2(cr) in agreement with the findings of Stewart (8). In the temperature range 298-900 K, the Gibbs energy change for the decomposition reaction $2\ CoF_3(cr) \rightarrow 2\ CoF_2(cr) + F_2(g)$ are in the range +10-20 kcal mol^{-1}.

$S°(298.15\ K) = 52.993 \pm 0.34\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2103 \pm 10\ K$

$\Delta_f H°(0\ K) = -238.1 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -237.7 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° =$ Unknown

Enthalpy of Formation

Boyle et al. (1) measured the enthalpy of combustion of metallic cobalt at 303.16 K. Their analyses of the combustion products indicated that some overoxidation of the metal had occurred. Correction of their results to correspond to CoO was made on the assumption that the excess oxygen was combined as Co_3O_4. Also the analyses indicated that the combustion products had attacked the silica-glass capsules, used to hold the metal samples, resulting in appreciable amounts of silicate formation. Corrections for these two side reactions amounted to three percent of the total measured energy of combustion. From these data, we derive $\Delta_f H°(CoO, cr, 298.15\ K) = -57.0 \pm 0.3\ kcal\ mol^{-1}$. Roth and Havekoss (2) also investigated calorimetrically the combustion of metallic cobalt and reported $\Delta_f H°(CoO, cr, 298.15\ K) = -57.2 \pm 0.2\ kcal\ mol^{-1}$.

2nd and 3rd law analyses of several equilibrium studies (3-12), emf measurements (13), and mass-spectrometric studies (14) involving CoO(cr) are discussed in the *JANAF Thermochemical Tables* (18), $\Delta_f H°(CoO, cr, 298.15\ K) = -56.82 \pm 0.10\ kcal\ mol^{-1}$ ($-237.735 \pm 0.4\ kJ\ mol^{-1}$) was adopted. A recent critical evaluation by Cyr et al. (19) recommended $\Delta_f H°(CoO, cr, 298.15\ K) = -237.5 \pm 0.4\ kJ\ mol^{-1}$, based on 2nd and 3rd law analyses. Since this value differs from the value previously adopted by JANAF by only 0.2 kJ mol^{-1} and includes ten new references in the evaluation, it is adopted for the current table.

Heat Capacity and Entropy

The adopted heat capacities for CoO(cr) in the temperature range 51-298 K are those of King (15). These data have a pronounced maximum at 287.3 K, at which point the heat capacity is greater than 17.6 cal $K^{-1}\ mol^{-1}$. Assayag and Bizette (16) also measured heat capacities for CoO(cr) between 180-400 K and reported a maximum at 298.7 K. Presumably this anomaly is of the magnetic type. Heat capacity data above 300 K are calculated from the high temperature (400-1800 K) enthalpy data of King and Christensen (17). Both sets of data were smoothed by computer and joined at 298.15 K.

The value of S°(298.15 K) is obtained from the low temperature heat capacity dataof King (15) and is based on S°(51 K) = 0.42 cal $K^{-1}\ mol^{-1}$.

Fusion Data

The adopted T_{fus} of 2103±10 K was recommended by IUPAC [20] based on the work of Coutures [21].

$S°(298.15\ K) = 117.377 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$T_{trs}\ (\alpha \rightarrow \beta) = 964 \pm 5\ K$

$\Delta_f H°(0\ K) = -878.95 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -888.26 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 2.134 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Adami and King (1) determined calorimetrically the enthalpies of solution of crystalline CoO and α-$CoSO_4$ in hydrochloric acid solution. From these measurements they derived the enthalpy for the reaction $CoO(cr) + H_2SO_4 \cdot 7.068\ H_2O(\ell) \rightarrow CoSO_4(cr) + 8.068\ H_2O(\ell)$ *as* $\Delta_r H°(298.15\ K) = -14.280 \pm 0.110$ *kcal* mol^{-1}. *Combining this result with enthalpies of formation for CoO (2)* $H_2SO_4 \cdot 7.068\ H_2O$ *(3), and* H_2O *(3), we derive* $\Delta_f H°(\alpha\text{-}CoSO_4, cr, 298.15\ K) = -212.3 \pm 0.3$ *kcal* mol^{-1} $(-888.263 \pm 1.3\ kJ\ mol^{-1})$ which is adopted.

The total pressures of $SO_3(g)$, $SO_2(g)$, and $O_2(g)$ over $CoSO_4(cr)$ in the temperature range 1100–1300 K have been determined by manometric (4–7) and transpiration (8) methods. Previous investigators (4–6) analyzed these data solely in terms of two equilibria, namely (A) $CoSO_4(cr) = CoO(cr) + SO_3(g)$ and (B) $SO_3(g) = SO_2(g) + 0.5\ O_2(g)$. However, Warner (10) has shown that *$CoSO_4$ takes part in three successive, univariant, decomposition equilibria as the temperature is increased.* Co_3O_4 is the decomposition product at low temperatures (<1150 K), a mixture of Co_3O_4 and CoO at intermediate tempertures, and CoO at high temperatures. Second and third law analyses of those points involving only equilibria (A) and (B) are given below. The appearance of Co_3O_4 *as a decomposition product was determined by comparing the oxygen partial pressures that were calculated* from the total pressure data with those for the decomposition reaction (C) $Co_3O_4(cr) \rightleftharpoons 3\ CoO(cr) + 0.5\ O_2(g)$ (2). Espelund and Flengas (9) measured the Gibbs energy of reaction (A) in a high temperature solid electrolytic cell. Here, no Co_3O_4 was formed over the entire temperature range (827–1133 K), since the oxygen pressures in the cell were too low to oxidize the CoO. Results of an analysis of these data are also given below:

Source	Reaction	Method	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Marchal (4)	A	Manometric	17	1143–1303	54.5	60.4±0.5	4.9 ±0.6	-211.8±0.8
Schenck and Raub (5)	A	Manometric	14	1099–1243	68.5	60.9±0.7	-6.3 ±1.1	-212.3±1.0
Warner (6)	A	Manometric	2	1164–1175	56.9	59.3±0.3	2.1	-210.8±0.3
Ingraham (7)	A	Manometric	9	1144–1210	59.1	59.1±0.1	0.04±0.91	-210.6±0.4
Alcock et al. (8)	D**	Transpiration	8	1131–1217	-191.1	-166.8±1.4	20.2 ±5.5	-211.2±1.5
Espelund and Flengas (9)	A	emf	28	827–1177	59.5	59.5±0.3	0.08±0.22	-211.0±0.6

** *Reaction:* (D) $2\ CoO(cr) + 2\ SO_2(g) + O_2(g) = 2\ CoSO_4(cr)$

These results indicate that the Gibbs energy functions and equilibrium data are consistent within experimental error.

Heat Capacity and Entropy

The low temperature (52–298 K) heat capacities are those reported by Weller (11). No anomalies appear in these data. *Heat capacities in the temperature range 300–2000 K are estimated by comparison with those for* $CuSO_4$ (2).

$S°(298.15\ K)$ is determined from the C_p data based on $S°(51\ K) = 1.56 + 2.75\ cal\ K^{-1}\ mol^{-1}$. The 1.56 is a lattice contribution, while the 2.75 is the entropy associated with the ordering of the Co^{+2} spin moments. In assigning the magnetic entropy, it is assumed that all of the contribution remains *to be extracted below the minimum temperature (52 K) of the heat* capacity measurements (11).

Transition Data

The temperature (T_{trs}) and the heat ($\Delta_{trs}H°$) of the α–β transition for $CoSO_4$ are from the differential thermal analysis studies of Ingraham and Marier (12). Other temperatures reported for the transition are 890 (8) and 903 K (13).

Decomposition Data

T_{dcm} is the temperature at which the Gibbs energy change for the process $CoSO_4(cr) \rightarrow CoO(cr) + SO_3(g)$ is zero.

J. Phys. Chem. Ref. Data, Vol. 1, Suppl. 1, 1971

$S°(298.15\ K) = 114.29 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -896.3 \pm 4.0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -910.0 \pm 4.0\ kJ\ mol^{-1}$

Enthalpy of Formation

Bugden and Pratt (1) measured Gibbs energies of reaction for (a) 2Cu(cr) + Co_3O_4(cr) + 3CoO(cr) + Cu_2O(cr) and (b) Ni(cr) + Co_3O_4(cr) + 3CoO(cr) + NiO(cr) from high temperature solid electrolytic cells. These data were subjected to 2nd and 3rd law analyses with results summarized in the following table:

Source	Reaction	Method	T/K	No. Of Points	$\Delta_r H°(298.15\ K)$ kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15K)$*
Bugden and Pratt (1)	a	emf	900-1150	Eqn	5.1	6.3±0.2	1.1	-217.5±0.8

O'Bryan and Parravano (9)	c	X-ray & Wt. Loss	1073-1243	Eqn	40.3	47.3±0.8	5.9	-217.8±1.0

*3rd law values based on $\Delta_f H°(CoO,cr, 298.15\ K) = -56.82 \pm 0.1$ kcal mol^{-1} (2).

Both sets of emf data are much more compatible with the adopted functions than the dissociation pressure data (see discussion below). The results obtained with the Cu/Cu_2O reference couple are judged to be more reliable and lead to the adopted enthalpy of formation, $\Delta_f H°(Co_3O_4,cr, 298.15\ K) = -217.5 \pm 1.0$ kcal mol^{-1}, when used in conjunction with JANAF (2) enthalpies of formation for CoO and Cu_2O.

Equilibrium oxygen pressures for the reaction (c) Co_3O_4(cr) = 3CoO(cr) + 0.5 O_2(g) have been determined by numerous investigators (3-9). 2nd and 3rd law analyses of these data are given in the above table. Within each set the 2nd and 3rd law $\Delta_r H°(298.15\ K)$ values are not in agreement, and all sets contain large positive drifts. Warner (10) has suggested that these discrepancies arise as a result of an error in the measured standard entropy (11) for Co_3O_4. However, once the magnetic contribution is included (see entropy write-up) the real error in this value is probably no greater than one cal K^{-1} mol^{-1}. The other possible source of error is lack of true equilibrium conditions. Recent thermogravimetric (9), X-ray (9), and kinetic (9, 12) studies of the Co_3O_4-CoO-O_2 system all point to an irreversible reaction. Therefore, no weight has been given to the dissociation pressure data in our evaluation.

Heat Capacity and Entropy

The low temperature heat capacities (54-296.3 K) are those reported by King (11). Heat capacities in the temperature range 300-1000 K are calculated from the high temperature enthalpy data of King and Christensen (13); a constrained curve fitting technique was used to join smoothly these data with the low temperature data at 298 K. No anomalies appear in either set of data.

Roth (14) observed a maximum in the magnetic susceptibility of Co_3O_4 at 40 K, while Mossbauer studies by Kundig et al. (15) indicated a Neel temperature of 33.0±1.0 K. With the assumption that Co_3O_4 is a normal 2-3 spinel (16), this transition can be associated with the antiferromagnetic ordering of the Co^{+2} ion spin moments. Therefore, the entropy is based on $S°(51\ K) = 1.36 + 2.75 = 4.11$ cal K^{-1} mol^{-1}, where 1.36 is a lattice contribution and 2.75 is the magnetic entropy. In assigning the magnetic entropy, it is assumed that all of the contribution remains to be extracted below the minmum temperature (54 K) of the heat capacity measurements.

Decomposition Data

T_{dcm} is the temperature at which the Gibbs energy change for the process Co_3O_4(cr) + 3CoO(cr) + 0.5 O_2(g) is zero.

Chromium (Cr) Cr_1(ref)

$S°(298.15\ K) = 23.618 \pm 0.21\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 311.5\ K$
$T_{fus} = 2130 \pm 20\ K$

$\Delta_f H°(0\ K) = 0\ k\ J\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0.0008\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 20.5 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity values for T ≤ 10 K are chosen to be the same as those adopted by Hultgren et al. (1). A graphical integration of these Cp° data yields S°(10 K) = 0.005 kcal mol^{-1} and H°(10 K) - H°(0 K) = 0.0252 cal mol^{-1}. These data also match well with the Cp° studies of Clusius and Franzosini (2). The adopted Cp° values are based on the following studies.

Source	Points	Method	T/K
(2)	76	Cp°	14.10-274.43
(3)	23	Cp°	56.1 -291.1
(4)	Smooth	Cp°	60-300
(5)	Graph	Cp°	268-324
(6)	Smooth	Cp°	273-1073
(7)	Smooth	drop	400-1500
(8)	48	drop	1267.2108
(9)	17	drop	303-1884
(10)	Smooth	Cp°	320-1800
(11)	26	drop	673-1339

The adopted Cp° values are obtained primarily by graphical techniques to ensure smoothness of the curve and a reasonable representation of the sometimes diverse results. A ΔCp° = 0 is also adopted across T_{trs}. Below 200 K, there is excellent agreement between three independent studies (2, 3, 4). Above 200 K these three studies drift apart by at most 0.06 kcal mol^{-1}. Above 298 K, there are considerable differences in the various sets of data, differences of the order of 0.2 kcal mol^{-1} being typical. In terms of enthalpy, the data of Jaeger and Rosenbohm (11) deviates from the adopted values by +150 to +350 cal mol^{-1}; the data of Lucks and Deem (9) by 0 to -450 cal mol^{-1}; the data of Hultgren and Land (7) by -13 to +60 cal mol^{-1}; and the data of Conway and Hein (8) by -190 to +250 cal mol^{-1}. Surprisingly the enthalpy study by Kirillin et al. (12) yields enthalpies which are crudely 2 kcal mol^{-1} less than the adopted values at 2000 K.

Fusion Data

See the liquid table for details.

Transition Data

Beaumont et al. (5) measured the heat capacity of 99.998% pure Cr in the region 268-324 K. The detailed Cp° measurements gave evidence of a lambda-type anomaly, the maximum occurring at 311.5 K. Beaument et al. (5) estimated the heat associated with this transition to be 1.4 cal mol^{-1}. Garnier and Salamon (13) used an extension of the ac calorimetric method to determine latent heat and heat capacity simultaneously. They concluded that annealing the Cr sample decreases the transition temperature and sharpens the peak. They also concluded that the transition was first order with a latent heat of 0.19 ± 0.04 cal mol^{-1} at a transition temperature of 311.5 K. Garnier and Salamon (13) calculated a latent heat of 0.23 ± 0.05 cal mol^{-1} and 0.25 ± 0.08 cal mol^{-1} from expansivity data and neutron-diffraction data, respectively. Sze and Meaden (14) observed a large step in specific heat measurements (50%) and estimated a latent heat of 0.47 cal mol^{-1}.

We adopt T_{trs} = 311.5 K and $\Delta_{fus}H°$ = 0.0002 kcal mol^{-1} based on the work by Garnier and Salamon (13). In addition we adopt ΔCp° = 0 across the transition. The nature of the transition is not understood at this time.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: CURRENT: June 1973

$S°(298.15\ K) = [36.205]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2130 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [26.068]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 20.5 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Cr(ℓ) at 298.15 K is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2130 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity for Cr(ℓ) is estimated as 9.4 cal K^{-1} mol^{-1} by analogy with other monatomic metals. The same value was adopted by Hutgren et al. (1). A glass transition is assumed at 1350 K. Below 1350 K, the Cp° values are those of the crystal. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The value for the enthalpy of melting is adopted as $\Delta_{fus}H° = 4.9 \pm 1.0$ kcal mol^{-1}. This value is calculated from $\Delta_{fus}S°$ = 2.3 cal K^{-1} mol^{-1}. This estimated entropy of melting is consistent with the recently accepted $\Delta_{fus}S°$ values for V (2, 2.49 cal K^{-1} mol^{-1}), Nb (2, 2.33 cal K^{-1} mol^{-1}), and Ta (2, 2.68 cal K^{-1} mol^{-1}). This is in contrast to a value of $\Delta_{fus}S° = 1.9$ cal K^{-1} mol^{-1} used by Hultgren et al. (1).

The melting temperature is adopted as T_{fus} = 2130 K as was chosen by Hultgren et al. (1). Values reported in the literature are:

Source	Year	T, K
(3)	1949	2133
(4)	1951	2118±10
(5)	1952	2176±10
(6)	1959	2122

Vaporization Data

The value for T_{vap} calculated as the temperature for which the Gibbs energy for the reaction Cr(ℓ) = Cr(g) is zero. The difference in the enthalpy of formation of Cr(ℓ) and Cr(g) at T_{vap} is $\Delta_{vap}H°$.

Enthalpy of Formation

The many vapor pressure studies are treated by a 2nd and 3rd law analysis and are tabulated below. In all cases the reaction of interest is Cr(cr) → Cr(g).

Source	Data Points	T/K	Method	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}

* Two points neglected due to failure of a statistical test.
** One point neglected due to failure of a statistical test.

Early studies by Greenwood (11) and Baur and Brunner (12) are not considered as their work leads to $\Delta_f H°(298.15\ K)$ which are 10-15 kcal mol^{-1} too low when compared to the results listed above.

We adopt $\Delta_f H°(298.15\ K)$ = 95.0 ± 1.0 kcal mol^{-1} for Cr(g). This value is representative of the more recent 2nd law values tabulated above (7, 8, 9, 10).

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from Moore (13); although only the lowest levels are listed above. There are predicted levels which have not been observed and/or classified. It is anticipated that these levels will not significantly alter the entropy below 3000 K. The heat capacity and entropy values are very similar to those adopted bvy Hultgren et al. (14).

Enthalpy of Formation

$\Delta_f H°(Cr^+, g, 0\ K)$ is calculated from $\Delta_f H°(Cr, g, 0\ K)$ (1) using the spectroscopic value of IP(Cr) = 54570 ± 10 cm^{-1} (652.80 ± 0.12 $kJ\ mol^{-1}$) from Sugar and Corliss (2). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Cr^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Cr, g, 0\ K)$ by using IP(Cr) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Cr(g), $Cr^+(g)$, and $e^-(g)$. $\Delta_f H°(Cr + Cr^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Corliss and Sugar (2), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first excited state, the highest observed excited state, and the ionization potential for $Cr^+(g)$, all levels listed by Sugar and Corliss (2), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that *for $Cr^+(g)$, the tehrmodynamic functions are independent of the estimated missing levels (for n=4), the cut-off procedure,* and the inclusion of n=6 levels up to 6000 K; the Gibbs energy function showing variations of 0.02% at this temperature. The reported uncertainty is S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>6), and use of different fill and cut-off procedures (6).

PREVIOUS: CURRENT: March 1984 (1 bar)

EA(Cr, g) = 0.666 ± 0.012 eV

$S°(298.15\ K) = 173.030 \pm 0.003\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 331.081 \pm 2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [327.024]\ kJ\ mol^{-1}$

Electonic Level and Quantum Weight

State	ϵ_i, cm^{-1}	g_i
$^6S_{5/2}$	0.0	6

Enthalpy of Formation

$\Delta_f H°(Cr^-, g, 0\ K)$ is calculated from $\Delta_f H°(Cr, g, 0\ K)$ (1) using the adopted electron affinity of EA(Cr) = 0.666 ± 0.012 eV (64.259 ± 1.158 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Cr^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Cr^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Cr, g, 0\ K)$ by using EA(Cr) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Cr^-(g)$, Cr(g), and $e^-(g)$. $\Delta_r H°(Cr^- \rightarrow Cr + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity of Entropy

The ground state electronic configuration for $Cr^-(g)$ is given by Hotop and Lineberger (2, 4) and Rosenstock et al. (5). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

$S°(298.15\ K) = 37.71 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -116.46 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -117.15 \pm 8.4\ kJ\ mol^{-1}$

Enthalpy of Formation

2nd and 3rd law analyses of equilibrium nitrogen pressures for the reaction $Cr_2N(cr) + 0.5\ N_2(g) = 2\ CrN(cr)$ cited in a recent review (1) of the thermodynamic properties of the Cr-N system are made using revised thermal functions for Cr_2N [2] and CrN (see below). We have not taken into account, in our analysis, any variations in the compositions of the two nitrides (see Phase Data Section). Results of our analysis are tabulated below.

Source	Data Points	T/K	$\Delta_r H°$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$[a] kcal mol^{-1}

Mills (6)	Equation	1173-1323	-25.1	25.26±0.02	-0.2	-27.6±1.0

[a]Third law values; auxiliary data used $\Delta_f H°(Cr_2N, cr, 298.15\ K) = -30.0 \pm 3.0$ kcal mol^{-1}.
[b]Data taken from reference (1); one point rejected due to failure of a statistical test.

The equilibrium pressures of Sano (4) are inconsistent with those of the other investigations, and no weight is given to these results. Reasons for these discrepancies have been presented by DeLuca and Leitnaker (1). The drifts are both positive and negative which provides support for our revised thermal functions for the two nitrides. Neumann et al. (7) measured $\Delta_f H°$ directly by combination of the elements in a bomb calorimeter. Two samples of chromium (99.2-99.7% purity) were heated to temperatures near 1200 K in 25 atmospheres of nitrogen. Under these conditions (8), it is unlikely that significant amounts of subnitride (Cr_2N) were formed. Neumann et al. (7) recommended the value $\Delta_f H°(CrN, cr, 298.15\ K) = -29.5 \pm 0.5$ kcal mol^{-1}.

We adopt $\Delta_f H°(CrN, cr, 298.15\ K)$ value of -28.0±2.0 kcal mol^{-1} (-117.152±8.4 kJ mol^{-1}) which is based mainly on the results from two equilibrium studies (3, 6) and to a lesser extent on the value determined by bomb calorimetry. Our adopted value agrees with that (-28.4±1.5) selected by DeLuca and Leitnaker (1) but is 1.8 kcal mol^{-1} less negative than the NBS (9) value (-29.8).

Heat Capacity and Entropy

One low temperature heat capacity study (10) has been reported for CrN which covered the temperature range 73-315 K. $C_p°$ values taken from the graph at 25° temperature intervals are used to obtain a value for S°(298.15 K) by integration. This method leads to S°(298.15 K) = 9.0 cal K^{-1} mol^{-1} (37.656 J K^{-1} mol^{-1}) with S°(73 K) = 0.39 cal K^{-1} mol^{-1}. The latter value is obtained from the Debye function D(530/T). The uncertainty in our value for S°(298.15 K) is believed to be less than ±0.5 cal K^{-1} mol^{-1}. Previously published estimates of S°(298.15 K) are 8.56 (1) and 7.85 (11). The low temperature data set (10) contains a lambda peak at 281.7 K with $C_p°$ near the maximum equal to 75.1 cal K^{-1} mol^{-1}. Other transition temperatures have been reported as 286 K (12) and 287 K (13). The anomaly arises from an antiferromagnetic-paramagnetic transformation (12, 13) which is accompanied by an orthorhombic to cubic structural change (14).

Satoh (15) has measured the heat contents of three chromium nitride samples at three temperatures each (372.6, 598.8, and 784.2 K), in an ice calorimeter. DeLuca and Leitnaker (1) have reevaluated his heat contents and presented $C_p°$ data for CrN in the temperature range 298-1400 K. Their values above 400 K are adopted and joined smoothly with the low temperature $C_p°$ data (10) near 350 K. $C_p°$ data above 1400 K are obtained by graphical extrapolation.

Phase Data

The homogeneity range of the CrN phase is not known; however, results of two recent studies (6, 12) indicate that it is probably much smaller than that for Cr_2N (2). X-ray diffraction patterns (16, 17) for CrN have been interpreted in terms of a cubic structure (NaCl type). Other information on the chromium-chromium nitride system has been reviewed by Storms (8).

Decomposition Data

No information is available on the melting point of CrN. Upon heating we assume that the compound decomposes to its elements rather than melting. T_{dcm} is the temperature at which $\Delta_r G°$ for the process $CrN(cr) = Cr(cr) + 0.5\ N_2(g)$ equals zero.

Enthalpy of Formation

Srivastava and Farber (1) have observed mass spectrometrically CrN(g) as one of the vapor species in equilibrium with the Cr-V-N system. A substitution reaction between VN and Cr was employed in the formation of gaseous mononitride in the temperature range 1900 to 2063 K. Ion intensities for the equilibrium species CrN, VN, V, and N_2 were measured and converted to partial pressures by means of an intensity-pressure relationship for Au(g). Results of a 2nd and 3rd law analysis of their pressure data (1) are given below.

Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)^a$, kcal mol^{-1} 2nd Law	3rd Law
A	7	1903-2063	-35.6	-27.18±0.75	4.3±2.3	130.6	122.2
B	7	1903-2063	21.3	22.42±0.33	0.6±1.3	118.1	119.2

Reactions: (A) CrN(g) = Cr(g) + 0.5 N_2(g) (B) VN(g) + Cr(g) = CrN9g) + V(g)

[a]Auxiliary $\Delta_f H°$ data (2) used (in kcal mol^{-1}): Cr(g), 95.0±1.0; VN(g), 125±5; V(g), 123.2±2.0.

We note that several of the log Kp values listed by Srivastava and Farber (1) for the two gas phase reactions are inconsistent with their reported partial pressure data. Since the 3rd law method is relatively insensitive to errors in the *equilibrium constant*, we believe the two 3rd law $\Delta_f H°$ values are more reliable than those obtained by the 2nd law. Thus, we adopt the average 3rd law value of $\Delta_f H°$(CrN, g, 298.15 K) = 120.7±5.0 kcal mol^{-1} (505.009±20.9 kJ mol^{-1}). Taking into account estimated errors in the pressure determinations and thermal functions, an overall uncertainty of ±5 kcal mol^{-1} is assigned. The adopted $\Delta_f H°$ value corresponds to a dissociation energy of $\Delta_{at} H°$(CrN, g, 298.15 K) = 87.3 kcal mol^{-1}.

Although no other experimental value for $\Delta_{at} H°$ is available, two estimations have been reported. Gingerich (4), using empirical correlations of Colin and Goldfinger (3) and Pauling (6), predicted a value of $\Delta_{at} H°$(CrN, g, 298.15 K) = 96 kcal mol^{-1} for CrN(g) by both methods. This predicted value is in reasonable agreement with that determined experimentally by *Srivastava and Farber (1) and reaffirms the usefulness of three empirical correlations (3-5)* in predicting dissociation energies for gaseous diatomic mononitrides.

Heat Capacity and Entropy

The value of r_e(CrN) is obtained from the expression r_e(MO) - r_e(MN) = -0.023 Å with r_e(CrO) = 1.627 Å (2). Differences in the bond lengths (7) for the oxides and nitrides of As, B, P, Si, and Ti are used to establish the value of -0.023. B_e is calculated from the estimated value for r_e. The moment of inertia is calculated to be 4.9881 x 10^{-39} g cm^2. The value of α_e is obtained from the other constants assuming a Morse potential function. The values of ω_e and $\omega_e x_e$ are assumed to lie between those for VO (2) and AsN (7).

CrN is isoelectronic with VO; therefore, the ground state electronic configuration is taken to be the same as that for VO (2). Also, the electronic levels and quantum weights are estimated by analogy with those for VO (2). Futher support for the *quartet ground state of CrN is provided by the fact* that the atomic levels for Cr^{+3} (8) are also quartets. Our adopted upper levels and quantum weights contribute 0.13 cal K^{-1} mol^{-1} to the entropy of CrN at 4000 K.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

CHROMIUM OXIDE (CrO) IDEAL GAS M_r = 67.9954

$S°(298.15\ K) = 239.268 \pm 6.3\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 187.85 \pm 41.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 188.28 \pm 41.8\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$X\ ^5\Pi$	0	10
$B\ ^5\Pi$	16584.5	10

$\omega_e = 898.8\ cm^{-1}$ $\omega_e x_e = 6.50^{-1}$ $\sigma = 1$

$B_e = 0.5286\ cm^{-1}$ $\alpha_e = 0.0050\ cm^{-1}$ $r_e = 1.627$ Å

Enthalpy of Formation

Based on the adopted ground state vibrational constants, a linear Birge-Sponer extrapolation yields a dissociation energy, of 3.796 eV (87.54 kcal mol^{-1}). Applying a correction for the ionicity in the Cr-O bond (1), we recalculate D_0^0 = 4.017 eV (92.63 kcal mol^{-1}). This in turn corresponds to $\Delta_f H°(298.15\ K)$ = 60.95 kcal mol^{-1} for CrO(g), using auxiliary data (2).

Huldt and Lagerqvist (3), using a spectroscopic flame technique, reported D_0^0 = 4.4±0.5 eV for CrO(g). This value was later corrected to D_0^0 = 5.3 eV (122.9 kcal mol^{-1}) (4, 5). Grimley et al. (6) mentioned that in determining D_0^0 values by the flame technique of Huldt and Lagerqvist (3), the calculation assumes that Cr and CrO are the only gaseous species containing Cr and that the CrO_2(g) partial pressure cannot be neglected under these experimental conditions.

Grimley et al. (6) studied the vaporization of Cr_2O_3(cr) under neutral and oxidizing conditions using mass spectrometric methods. The reported partial pressure data for Cr(g), CrO(g), CrO_2(g), O(g), and O_2(g) may be analyzed in terms of many different chemical equilibria. Our analyses of four equilibria in the neutral and oxidizing conditions are tabulated below.

	Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1} 2nd Law	3rd Law
Neutral conditions	A*	-39.5	-44.9	-2.8±2.1	55.5	50.1
1842-2062 K	B	-108.2	-100.4	4.0±1.4	46.3	54.2
13 points	C	174.0	178.2	2.1±1.2	38.4	42.6
	D*	206.3	205.9	-0.2±1.4	40.9	40.5
Oxidizing conditions	A	-27.2	-43.7	-8.6±13.1	67.8	51.3
1893-1945 K	B	-46.9	-99.3	-27.3±4.0	107.6	55.2
3 points	C	192.2	181.0	-5.8±4.4	56.6	45.4
	D	202.0	208.9	3.6±9.0	36.6	43.5

Reaction A: $Cr(g) + 1/2\ O_2(g) = CrO(g)$ C: $1/2\ Cr_2O_3(cr) = CrO(g) + 1/4\ O_2(g)$

B: $Cr(g) + O(g) = CrO(g)$ D: $1/2\ Cr_2O_3(cr) = CrO(g) + 1/2\ O(g)$

*One point rejected due to a statistical test (1842 K).

The drifts are less severe in the netural system so that there is better agreement in the 2nd and 3rd law results for the neutral conditions than in the oxidizing system. Note that the 3rd law $\Delta_r H°(298.15\ K)$ values are slightly more positive for the oxidizing than the netural conditions for corresponding equilibria. The calculated $\Delta_f H°(298.15\ K)$ values for the gas phase (reactions A and B) are about 10 kcal mol^{-1} higher than those of the condensed phase (reactions C and D) equilibria. Grimley et al. (6) prefer the gas phase results while Brewer and Rosenblatt (7) prefer the condensed phase results. We adopt $\Delta_f H°(CrO, cr, 298.15\ K)$ = 45.0±10.0 kcal mol^{-1} (188.280±41.8 kJ mol^{-1}) as a value which is representative of the 2nd and 3rd law results in the neutral system. The adopted $\Delta_f H°$ value leads to D° = 4.71 eV (108.6 kcal mol^{-1}).

Chizhikov et al. (8) also studied the vaporization of Cr_2O_3 via mass spectrometry in the range 1690-2020 K. They reported the detection of gaseous Cr, CrO, CrO_2, and O during the evaporation process. The reported smoothed partial pressures of CrO(g) and CrO_2(g) lie higher than those reported by Grimley et al. (6) by a factor of 2-5, while the partial pressures of Cr(g) are less than a factor 2 different. These data were not analyzed.

Heat Capacity and Entropy

The spectroscopic work involving CrO(g) has been reviewed and referenced by Rosen (9). The adopted vibration and rotation constants as well as the electronic levels are those tabulated by Rosen (9). The ground state has not been firmly established. Weltner (10) suggested a possible $^3\Sigma^-$ ground state. The free energy functions used here are 1.02 cal $K^{-1}mol^{-1}$ at 298 K and 1.57 cal K^{-1} mol^{-1} at 3000 K lower than those suggested by Brewer and Rosenblatt (7). The difference arises in that Brewer and Rosenblatt (7) approximated the CrO electronic levels with Cr^{++} electronic levels. The latter has a singlet ground state and many levels lying below 600 cm^{-1}.

Enthalpy of Formation

Grimley et al. (1) studied the vaporization of Cr_2O_3(cr) under neutral and oxidizing conditions using mass spectrometric methods. In the range 1842-2062 K (IPTS-68) this study detected quantitatively Cr(g), CrO(g), CrO_2(g), O(g), and O_2(g). Of the many chemical equilibria which could be analyzed, we tabulated below our 2nd and 3rd law analyses of the equilibrium between CrO(g) and CrO_2(g).

	$\Delta_r H°(298.15\ K)$ kcal mol^{-1} 2nd Law	3rd Law	Drift cal $K^{-1} mol^{-1}$	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Neutral system, 13 points, 1843-2062 K				
Reaction A**	141.27	119.87	-10.9±3.6	-15.31
Reaction B**	71.11	64.41	-3.4±2.8	-19.41
Oxidizing system, 3 points, 1893-1945 K				
Reaction A	120.97	122.48	0.8±9.2	-17.92
Reaction B	101.21		-17.9±0.1	-21.82

** One point (1865 K) rejected due to a statistical test.

Reactions: (A) $CrO_2(g) = CrO(g) + O(g)$. (B) $CrO_2(g) = CrO(g) + 1/2\ O_2(g)$.

We adopt $\Delta_f H°(298.15\ K) = -18.0 \pm 10.0$ kcal mol^{-1} (-75.312 ± 41.8 kJ mol^{-1}). This value is intermediate to the four results tabulated above with extra weight given to those of the neutral conditions. Our analysis of equations analogous to those treated in the CrO(g) table (3) yields the same trends as with CrO(g). The results are consistent with our adopted value.

Using auxiliary data (3), we calculate $\Delta_{at} H°$ = 9.98 eV (230.1 kcal mol^{-1}) corresponding to $CrO_2(g) = Cr(g) + 2\ O(g)$. This value is a factor of 2.12 greater than $D_0^0(CrO,g)$ (3).

Chizhikov et al. (2) also studied the vaporization of Cr_2O_3 via mass spectrometry in the range 1690-2020 K. They reported the detection of gaseous Cr, CrO, CrO_2, and O during the evaporation process. The reported smoothed partial pressures of CrO(g) and CrO_2(g) lie higher than those of Grimley et al. (1) by a factor of 2-5, while the partial pressures of Cr(g) are less than a factor of two difference. This study was not further analyzed.

Mass spectrometric studies were made by Farber and Srivastava (7) on the reactions involved with vanadium and chromium additives in potassium-seeded H_2/O_2 flames. Equilibrium values at an average flame temperature of 2250 K for the reaction for $CrO_2(g) + 2\ H_2O(g) = H_2CrO_4(g) + 2\ H(g)$ were analyzed by Farber and Srivastava (7). They calculated $\Delta_f H°(298.15\ K) = -3.0 \pm 7$ kcal mol^{-1} for CrO_2(g). The experimental determination of $\Delta_f H°(298.15\ K)$ for H_2CrO_4(g) also required the $\Delta_f H°(298.15\ K)$ value for CrO(g). Adjusting the calculations of Farber and Srivastava (7) to be consistent with the JANAF $\Delta_f H°(298.15\ K)$ value for CrO(g) (3), we recalculate $\Delta_f H°(298.15\ K) = -11.0$ kcal mol^{-1} for CrO_2(g).

Heat Capacity and Entropy

CrO_2(g) is assumed to have a molecular geometry similar to that observed for TiO_2(g), ZrO_2(g), and TaO_2(g) (3). The O-Cr-O bond is estimated as 110° while the Cr-O bond distance is estimated to be the same as that in CrO(g) [3]. The symmetric and asymmetric stretching frequencies are obtained from the infrared spectra of gaseous tetrahedral CrO_2Cl_2 and CrO_2F_2 (4, 5). The bending frequency of 300 cm^{-1} is estimated, based on analogies with TaO_2(g) and WO_2(g) (3, 6). Refer also to the TiO_2 ideal gas table (3). The electronic ground state is assumed to be $^3A_1$ as in WO_2(g) (6). The principal moments of inertia are: $I_A = 2.8646 \times 10^{-39}$, $I_B = 9.4383 \times 10^{-39}$, and $I_C = 12.3029 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

The vaporization of Cr_2O_3 under oxidizing conditions was studied by Grimley, Burns, and Inghram (1) using mass spectrometric methods. The principal gaseous species observed were Cr, CrO, CrO_2, CrO_3, O, and O_2. The vapor pressures at three different temperatures (1893, 1914, and 1942 K, IPTS-68) are analyzed for four different reactions by the 2nd and 3rd law methods.

Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Cr(g) + 3 O(g) = CrO_3(g)	-279.80	-332.47	-27.5±6.4	-58.79
Cr(g) + 1.5 O_2(g) = CrO_3(g)	-220.52	-165.48	28.7±21.1	-70.48
0.5 Cr_2O_3(cr) + 1.5 O(g) = CrO_3(g)	-30.81	-24.28	3.4±1.4	-70.04
0.5 Cr_2O_3(cr) + 0.75 O_2(g) = CrO_3(g)	-1.17	59.22	31.5±12.4	-75.88

The 2nd law results are considered less reliable due to the small number of data points and the small temperature range studied (52 K). We adopt $\Delta_f H°(CrO_3, g, 298.15\ K)$ = -70.0±10 kcal mol^{-1} (-292.880±41.8 kJ mol^{-1}).

Washburn (3), in a mass spectrometric study of the sublimation of CrO_3(cr), stated that the gaseous Cr-containing molecules are in equilibrium among themselves but not with O(g). If the same situation were to hold in the study by Grimley et al. (1), a value intermediate to -70.04 and -75.88 kcal mol^{-1} might be more appropriate. However, the adopted value with its assigned uncertainty is still consistent with this possibility.

Mass spectrometric studies were made by Farber and Srivastava (6) on the reactions involved with vanadium and chromium additives in potassium-seeded H_2/O_2 flames. Equilibrium values at an average flame temperature of 2250 K for the reaction $CrO_3(g) + H_2O(g) = H_2CrO_4(g)$ were analyzed by Farber and Srivastava (6). They calculated $\Delta_f H°(298.15\ K)$ = -64.6±7 kcal mol^{-1} for CrO_3(g). The experimental determination of $\Delta_f H°(298.15\ K)$ for H_2CrO_4(g) also required the $\Delta_f H°(298.15\ K)$ value for CrO(g). Adjusting the calculations of Farber and Srivastava (6) to be consistent with the JANAF $\Delta_f H°(298.15\ K)$ value for CrO(g) (2), we recalculate $\Delta_f H°(289.15\ K)$ = -72.6 kcal mol^{-1} for CrO_3(g).

Defining the dissociation by $CrO_3(g) = Cr(g) + 3O(g)$, we calculate $\Delta_{at} H°$ = 14.8±0.4 eV (340.3±10 kcal mol^{-1}). This compares with D_0^0 = 4.71 eV for CrO(g) and $\Delta_{at} H°$ = 9.98 eV for CrO_2(g) for similar dissociations (2).

Heat Capacity and Entropy

The molecular structure is assumed to be planar with D_{3h} symmetry. The three Cr-O bond distances are taken to be the same as in CrO(g) (2). The principal moments of inertia are $I_A = I_B$ = 10.5494 x 10^{-39} and I_C = 21.0987 x 10^{-39} g cm^2.

Barraclough et al. (4) observed a vibrational frequency at 969 cm^{-1} in the infrared spectrum of CrO_3(cr) dispersed in a Nujol mull. This frequency was assigned to represent the stretching frequency of the two free Cr-O groups in crystalline CrO_3. We assume this frequency also represents the stretching mode in the vapor phase. This infrared work is supported by the infrared and Raman studies of Mattes (5). The remaining vibrational frequencies are those suggested by Grimley et al. (1). The electronic ground state is assumed to be a singlet.

PREVIOUS: December 1973 (1 atm) CURRENT: December 1973 (1 bar)

CHROMIUM NITRIDE (Cr_2N) CRYSTAL M_r = 117.9987

$S°(298.15\ K) = [64.85 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -125.52 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

Mah (1) has measured the enthalpy of combustion of chromium subnitride at 303.15 K. From her data for the process $Cr_2N_{0.969}(cr) + 1.50_2(g) = Cr_2O_3(cr) + 0.4845\ N_2(g)$, we calculate $\Delta_c H°(298.15\ K) = -241.29 \pm 1.5$ kcal mol^{-1} at unit fugacities of oxygen and nitrogen. Impurity corrections are based on JANAF enthalpy of formation data (2). When the value for $\Delta_c H°$ is combined with the enthalpy of formation for Cr_2O_3 (2), one obtains $\Delta_f H°(Cr_2N_{0.969}, cr, 298.15\ K) = -29.9 \pm 3.5$ kcal mol^{-1}. The large uncertainty arises from impurities in the subnitride sample, as well as from the uncertainty (± 2.0 kcal mol^{-1}) in the $\Delta_f H°$ of Cr_2O_3 (2).

All available equilibrium nitrogen pressures except those of one study (5) have been recently reviewed for the reaction $2\ Cr(cr) + 0.5\ N_2(g) = Cr_2N(cr)$. These results are reanalyzed by the 2nd and 3rd law methods using revised thermal functions for Cr_2N (see below). We have not taken into account in our analysis any variations in the composition of the subnitride.

Source	Data Points	T/K	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law
Sano (4)	6	1229-1395	-3.7±0.2	-24.0	-28.8±0.5
Mozgoväi and Samarin (5)	Equation	1600-1750	-14.0	-10.2	-33.8±1.7
Seybolt and Oriani (6)	5	1273-1673	-7.8±5.4	-21.3	-32.8±3.9

Mills (8)	Equation	1337-1653	-2.1	-29.2	-32.3±0.5
Schwerdtfeger (9)	3	1373-1583	-3.7±0.7	-27.1	-32.5±0.8
Smith (10)	2	1333-1370	-13.4	-13.6	-31.7±0.7

We adopt $\Delta_f H°(Cr_2N, cr, 298.15\ K) = -30.0 \pm 3.0$ kcal mol^{-1} (-125.52 ± 12.6 kJ mol^{-1}) which is based on the 2nd and 3rd law results from the two equilibrium studies (8, 9) and the $\Delta_f H°$ value determined by combustion calorimetry (1). Our adopted value agrees with that selected by NBS (-30.5) (11) but is 1.8 kcal mol^{-1} less negative than the selected value of DeLuca and Leitnaker (3).

Heat Capacity and Entropy

No low temperature heat capacity data for Cr_2N have been reported. By analogy with entropies (2, 12, and 13) for other transition-metal subnitrides, for the reaction $2\ M(cr) + 0.5\ N_2(g) = M_2N(cr)$ where M=Fe, Mo, Nb, Ta, and V, we calculate an average $\Delta_f S°$ of -18.7 cal K^{-1} mol^{-1}. This value is combined with entropies for Cr and N_2 (2) to give 15.5 cal K^{-1} mol^{-1} as $S°(298.15\ K)$ for $Cr_2N(cr)$. Other reported estimates in cal K^{-1} mol^{-1} for $S°(298.15\ K)$ are 14.3 (3) and 17.7±1.0 (14).

The only high temperature enthalpy study reported for Cr_2N is that of Satoh (15), who measured heat contents $[H°(T) - H°(273.15\ K)]$ three nitride samples at three temperatures each (372.6, 598.8, and 784.2 K) in an ice calorimeter. DeLuca and Leitnaker (3) have shown that the subnitride sample used by Satoh (15) was substoichiometric, reevaluated his heat contents and presented $C_p°$ data for Cr_2N in the temperature range 298-1800 K. A comparison of their value (17.0 cal K^{-1} mol^{-1}) for $C_p°(298.15\ K)$ with similar data for other transition-metal subnitrides (2, 12, 13) indicates it is probably too large by 1-2 cal K^{-1} mol^{-1}.

We find a $\Delta_f C_p°$ of 1.1 cal K^{-1} mol^{-1} for several subnitrides (2, 12, 13) which leads to a $C_p°$ value of 15.79 cal K^{-1} mol^{-1} for Cr_2N at 298.15 K. This value is adopted and joined smoothly with the data of Deluca and Leitnaker (3) near 400 K. $C_p°$ data above 1800 K are obtained by graphical extrapolation.

Phase Data

Blix (16) has determined the structure of the subnitride phase as hexagonal by x-ray diffraction methods, and he indicated that the homogeneity limits extend from $CrN_{0.47}$ to $CrN_{0.66}$. Eriksson (17) has reported that the phase exists between $CrN_{0.38}$ and $CrN_{0.50}$. Mills (8), using a thermogravimetric technique, has examined the homogeneity limits of Cr_2N as a function of temperature. The upper limiting composition was determined to be $CrN_{0.49}$ with only a small variation with temperature. The lower limiting composition of Cr_2N varied widely with temperature in the range 1273-1373 K. Mills (8) reported the limiting composition as $CrN_{0.41}$, at 1273 K and $CrN_{0.37}$ at 1373 K. Other information on the chromium-chromium nitride system has been reviewed by Storms (18).

Decomposition Data

No information is available on the melting point of Cr_2N. We assume that the subnitride decomposes prior to melting, according to the reaction $Cr_2N(cr) \rightarrow 2\ Cr(cr) + 0.5\ N_2(g)$. T_{dcm} is the temperature at which $\Delta_r G°$ for the decomposition process equals zero.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

CHROMIUM OXIDE (Cr_2O_3) CRYSTAL M_r = 151.9902

$S°(298.15\ K) = 81.15 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2603 \pm 15\ K$

$\Delta_f H°(0\ K) = -1128.84 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1134.70 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [129.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

Two oxygen bomb calorimetric studies on Cr(cr) led to reported values of $\Delta_f H°(Cr_2O_3, cr, 298.15\ K) = -272.6 \pm 0.4$ kcal mol^{-1} by Mah (1) and -271.0 ± 1.8 kcal mol^{-1} by Golutvin and Chin'k'uei (2). Mah (1) reported that completions of combustion ranged from 95.30 to 98.90% and applied corrections. Of the fourteen runs by Golutvin and Chin'k'uei (2), seven had a completeness of combustion of 91.88 to 98.96%. Their reported $\Delta_f H°(298.15\ K)$ value is based on an average of the results for these seven runs with no correction for incomplete combustion or impurities. These latter authors (2) also stated that there was no clear dependence between the enthalpy of combustion and completeness of combustion. Early calorimetric studies led to reported values for $\Delta_f H°$ of -267.8 (298 K, 3), -288.9 ± 1.0 (292 K, 4), and -268.9 ± 0.6 kcal mol^{-1} (294 K, 5).

There are many equilibrium studies involving Cr_2O_3(cr). Our analysis of the more recent studies are tabulated below. The *free energy of formation* equation presented by Richardson and Jeffes (8) is representative of the earlier equilibrium studies (9).

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law

(12)	A(emf)	1000-1700	Eqn.	-264.60	-268.91	-3.3	-264.60	-268.91
(13)	A(emf)	1173-1523	Eqn.	-269.71	-270.32	-0.5	-269.71	-270.32

Reactions: (A) $2\ Cr(cr) + 3/2\ O_2(g) = Cr_2O_3(cr)$. (B) $2/3\ Cr(cr) + H_2O(g) = 1/3\ Cr_2O_3(cr) + H_2(g)$.

We adopt $\Delta_f H°(Cr_2O_3, cr, 298.15\ K) = -271.2 \pm 2.0$ kcal mol^{-1} (1134.701±8.4 kJ mol^{-1}). This value is an average of two combustion studies (1, 2) and three equilibrium studies which have a small third law drift (10, 11, 13).

Kelly et al. (6) investigated experimentally the thermodynamic properties of the chromium carbides. They measured the CO(g) equilibrium pressure in four distinct systems. A combination of our analyses of these four equilibria (7) leads to $\Delta_f H°(Cr_2O_3, cr, 298.15\ K) = -269.9$ kcal mol^{-1}.

Heat Capacity and Entropy

The heat capacity of Cr_2O_3(cr) was measured by Anderson [14 (56-336 K)] and by Volger (graph, 100-350 K, 15). Using the combination of Debye and Einstein functions suggested by Anderson (14), we calculate $S°(50\ K) = 0.386$ cal K^{-1}mol^{-1} and $H°(50;0) = 14.3$ cal mol^{-1}. Both studies (14, 15) indicated a maximum in the $C_p°$ curve at 205 K. The data of Volger (15) lies considerably higher than that of Anderson (14). Early heat capacity data by Russell (137-299 K, 16) is in good agreement with that of Anderson (14). Above 305 K the heat capacity values decrease rapidly (~5 cal K^{-1}mol^{-1}) until 325-340 K, at which point the values show little change with temperature. The adopted $C_p°$ values below T = 330 K are based on the study by Anderson (14).

Enthalpy data on Cr_2O_3(cr) were measured by Kelley et al. (298-1774 K, 6) and Laschschenko and Kompanskii (288-1428 K, 17). The adopted heat capacity values are those suggested by Kelley et al. (6), except that the values in the region 350-500 K are shifted slightly so as to join smoothly with the low temperature heat capacity results (14). The derived enthalpy values agree with the enthalpy data of Kelley et al. (6) to within ±0.5%, the maximum deviation of 25 cal or .5% occurring at 479 K.

Phase Data

Brewer (18) summarized the phase data and *reported that* Cr_2O_3 *has a homogeneity range of* x = 1.50-1.56 for CrO_x. Cr_2O_3 has the α-corundum structure and is antiferromagnetic with structural distortion occurring below the Curie temperature of 305 K.

Fusion Data

See the liquid table for details.

PREVIOUS: CURRENT: December 1973

CHROMIUM OXIDE (Cr_2O_3) LIQUID M_r = 151.9902

$S°(298.15\ K) = [125.595]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2603 \pm 15\ K$

$\Delta_f H°(298.15\ K) = [-1018.381]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [129.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Cr_2O_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2603 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity for $Cr_2O_3(\ell)$ is estimated to be 7.5 cal K^{-1} mol^{-1}. A glass transition is assumed at 1800 K. Below 1800 K, the $C_p°$ values are those of the crystal with the exception that the values below 500 K are a smooth extrapolation to $C_p°$ = 24.32 cal K^{-1} mol^{-1} at 298.15 K.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point is chosen to be T_{fus} = 2603±15 K, as suggested by Charlesworth (1). This result is based on the work by McNally et al. (2). The heat of melting is estimated by analogy with $\Delta_{fus}S°$ = 12.03 for corundum (3).

CESIUM (Cs) CRYSTAL A_r = 132.9054

$S°(298.15\ K) = 85.147 \pm 0.21\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 301.55 \pm 0.01\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{fus} H°(923\ K) = 2.087 \pm 0.004\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities, 0.19-301.55 K, have been measured by Dauphinee (1), McCollum (2), Martin (3), Lien (4), Filby (5), and Morgan (6). The adopted values are derived based on the Cp data reported by Filby (5) and Lien (4). Lien measured the heat capacities in the temperature range 0.1874 to 1.20K in the adiabatic demagnetization cryostat and at higher temperatures, 1.2 to 4.09°K, in the liquid-helium temperature cryostat. The Cs sample was obtained from a commercial source of 99.8 per cent purity. Filby determined the Cp values in the temperature ranges 0.4-1.5 K, 3-26 K and 20-320 K, using commercial samples of 99.9 per cent purity. These two sets of measurements are joined smoothly at 4 K. S°(298.15 K) is derived from the adopted heat capacities, based on $S°(0.20\ K) = 0.0002\ cal\ K^{-1}\ mol^{-1}$. Dauphinee (1) determined the heat capacities of Cs(cr) employing a sample badly contaminated with oxygen. In the temperature range of approximately 100 to 200 K, an anomaly of Cp curve somewhat similar to those found for sodium and potassium was reported. This anomaly was not observed by Filby who used the higher purity cesium sample. The Cp values reported by Dauphines are lower than the adopted ones by about 0.5 to 1.5 per cent in the temperatures 55 to 220 K; above 270 K his reported heat capacities are unreasonably high. Therefore the data are not adopted for evaluation. McCollum (2) calculated the Debye θ values from the measured low temperature heat capacities and plotted them, since no numerical data were reported these were not used. The low temperature Cp values determined by Martin (3) and Morgan (6) are in good agreement with the adopted ones.

Fusion Data

See the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ is calculated as the difference between $\Delta_f H°(298.15\ K)$ for Cs(g) and Cs(cr).

$S°(298.15\ K) = [92.069]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 301.55 \pm 0.01\ K$

$\Delta_f H°(298.15\ K) = [2.087]\ kJ\ mol^{-1}$

$\Delta_{fus} H°(301.55\ K) = 2.087 \pm 0.004\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Cs, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion and the difference in enthalpy, $H°(301.55\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The enthalpies of Cs(ℓ) have been measured by Tepper et al. (1), Achener (2), and Lemmon et al. (3), using drop calorimetry. Lemmon et al. used a cesium sample of 99.994 per cent purity and encapsulated in Nb-1Zr alloy. They found that Cs(ℓ) does not behave as a normal liquid from about 100-300°C. The thermal conductivity measurements of Cs(ℓ) show a change of slope at about 200°C and its electrical resistivity also shows scatter in this region. The heat capacities, 301.55 - 1435.2 K, derived from the reported enthalpies (corrected for vapor condensation), are consistent with the low temperature heat capacity data on Cs(cr) at 298.15 K and are adopted.

Tepper et al. measured the enthalpies in the temperature range 351.1 - 1238 K. The reported enthalpy values are considerably higher, over 20 per cent, at the lower end of the measured temperature range than the adopted ones. However, the agreement becomes better at the higher temperature end. Achener determined the enthalpies of Cs(ℓ) at the temperatures 340.1 - 1175.7 K. Using the reported enthalpies, the average heat capacity is derived to be 9.75 kcal mol^{-1}, which is unreasonably high by comparison with those for the other alkali metals. The above two sets of data are not used for evaluation. The enthalpies of Cs(ℓ), 773 - 1423 K, were also measured by Shapiro (4 and quoted by 3). The derived constant heat capacity, 7.60 cal mol^{-1}, is in reasonable agreement with the adopted ones.

Heat capacities of Cs(ℓ), 301.55-373.2 K, were reported by Filby (5), 301.55-320 K, Dauphinee (6), 310-320 K, and Rengade (7), 301.7-373.2 K. The values obtained are consistent with the adopted ones.

S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point and enthalpy of melting have been determined by many investigators. The results reported are presented in the table below. The adopted T_{fus} and $\Delta_{fus}H°$ are obtained from (5). The two determinations of fraction melted against temperature are in very good agreement with one another and lead to a linear plot of reciprocal fraction melted against temperature thus indicating that the major impurity is solid insoluble. This is confirmed by a graph of excess heat capacity against the reciprocal of $(T_0-T)^2$, where T_0 is the melting point, which indicates an impurity (mainly oxygen) concentration of 0.06 atomic per cent.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change for the reaction Cs(ℓ) = Cs(g) is zero. The differences between $\Delta_f H°(Cs, g)$ and $\Delta_f H°(Cs, \ell)$ at T_{vap} is $\Delta_{vap}H°$. Due to the presence of dimer (Cs_2) in the vapor, the boiling point (1 atm) of Cs(ℓ) is calculated to be 941.3 K at which the vapor mixture contains 0.835 mol of monomer/mol of Cs(ℓ) vaporized, or 9.0 per cent of dimer. The corresponding enthalpy of vaporization is evaluated as 15.26 kcal mol^{-1} of vapor mixture.

Enthalpy of Formation

The enthalpy of formation of cesium gas is chosen to be the value recommended by CODATA (1). This value was obtained from 2nd and 3rd law treatments of vapor pressure data. The reported vapor pressure were corrected for the effects of Cs(g), using D_0^0 = 38.02 kJ mol^{-1}. At higher pressures an alternate virial treatment was employed. As stated by CODATA (1), the selected value is the weighted average of the 3rd law values of $\Delta_{sub}H°(298.15\ K)$ from the following:

Source	$\Delta_{sub}H°(298.15\ K)$, kJ mol^{-1}
Taylor and Langmuir (2)	76.71 ± 0.64
Bonilla et al. (3)	76.20 ± 1.28
Achener (4)	76.66 ± 1.08
Tepper et al. (5)	78.08 ± 1.05
Bohdansky and Schins (6)	76.10 ± 0.95
Stone et al. (7)	76.52 ± 1.08
Buck and Pauly (8)	76.77 ± 0.75
Shpil'rain and Belova (9)	76.62 ± 1.06
Volyak et al. (10)	76.48 ± 0.77
Novikov and Rosupkin (11)	76.57 ± 1.19
Ewing et al. (12)	76.44 ± 1.48
Shpil'rain et al. (13)	76.50 ± 1.12
Schins et al. (14)	76.34 ± 0.90
Shpil'rain and Nikanorov (15)	76.46 ± 1.21
Behrens et al. (16)	77.22 ± 1.15

The 2nd law calculations from the above sources led to values somewhat more positive (1)

Heat Capacity and Entropy

The thermal functions for the five alkali metal monatomic gases are calculated by the same procedure. Oberved and estimated atomic energy levels are included in the partition function calculation, using an ionization potential lowering (IP-kT) technique as the cutoff procedure in the energy level summation (19).

The lowest lying levels for these metals [14904 cm^{-1} (Li), 16956 cm^{-1} (Na), 12985 cm^{-1} (K), 12578 cm^{-1} (Cs)] do not contribute to the thermal functions below ~1000 K; there is only a translational contribution below this temperature. Above this approximate temperature, the thermal functions become increasingly sensitive to the partition function cutoff procedure used, due to the combined effect of the observation of atomic energy levels of high principal quantum number and a low ionization potential. Energy levels have been observed up to n = 42 (Li), 59(Na), 79(K), 77(Rb), and 73(Cs). However, not all predicted levels have been observed for each of these principal quantum numbers. The ionization potentials vary from 43487.29 cm^{-1} for Li to 31406.1 cm^{-1} for Cs. In calculating the thermal functions with the inclusion of missing levels up to the high principal quantum numbers just mentioned, the Gibbs energy functions show significant differences (depending on the cutoff procedure) above 3000 K (17).

The atomic energy levels have been taken from the compilation of Moore (18, 19). Our calculated values for the thermal functions are similar to those recommended by CODATA (1). They do differ for two reasons, however. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, the entropies at 298.15 K for all alkali metal gases differs by ~0.004 J K^{-1} mol^{-1}, presumably due to the use of slightly different values for auxiliary data.

PREVIOUS: June 1968 (1 atm) CURRENT: December 1983 (1 bar)

CESIUM, ION (Cs^+) IDEAL GAS Mr = 132.90485

$IP(Cs^+, g) = 202263 \pm 2\ cm^{-1}$

$S°(298.15\ K) = 169.836 \pm 0.005\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 453.72 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [458.402]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	$\varepsilon_i\ cm^{-1}$	g_i
$^1S_0$	0	1

Enthalpy of Formation

$\Delta_f H°(Cs^+, g, 0\ K)$ is calculated from $\Delta_f H°(Cs, g, 0\ K)$ (1) using the spectroscopic value of IP(Cs) = 31406.432 ± 0.010 cm^{-1} (375.704 ± 0.001 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Cs^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Cs, g, 0\ K)$ by using IP(Cs) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Cs(g), $Cs^+(g)$, and $e^-(g)$. $\Delta_f H°(Cs \rightarrow Cs^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state; the first excited state is approximately 107392 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

Enthalpy of Formation

The enthalpy of formation, at 0 K, for $Cs^-(g)$ is calculated from the adopted electron affinity, EA(Cs, g) = 0.471630 ± 0.000025 eV, (45.505 ± 0.002 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (7), was measured by a tunable laser photodetachment threshold technique (4, 5). Additional discussion on $Cs^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (1, 7), Rosenstock et al. (2), and Massey (3).

$\Delta_f H°(Cs^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Cs, g, 0\ K)$ by using EA(Cs, g) with JANAF (6) enthalpies, $H°(0\ K)-H°(298.15\ K)$, for $Cs^-(g)$, Cs(g), and $e^-(g)$. $\Delta_r H°(Cs^- + Cs + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (2). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Cs^-(g)$ is given by Hotop and Lineberger (1, 7) and Rosenstock et al. (2). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

CESIUM FLUORIDE (CsF) CRYSTAL M_r = 151.903803 Cesium Fluoride (CsF) Cs_1F_1(cr)

$S°(298.15\ K) = [88.3 \pm 8]\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 976\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -554.7 \pm 2\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 21.7\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of solution ($\Delta_{sol}H°$) of CsF(cr) in water at 298.15 K has been carefully determined with an adiabatic calorimeter by Somsen (1). Based on the reported value, $\Delta_{sol}H°(298.15\ K) = -8.62 \pm 0.04$ kcal mol^{-1} and $\Delta_f H°(298.15\ K) \approx -61.69$ (2) and -79.5 kcal mol^{-1} (3) for Cs^+(ag, ∞) and F^-(ag, ∞), respectively, the enthalpy of formation for CsF(cr) is calculated to be -132.57 kcal mol^{-1} which is adopted.

The value, $\Delta_{sol}H°(298.15\ K) = -8.81 \pm 0.2$ kcal mol^{-1} for CsF(cr), was reported by Parker (4) which is in agreement with the value measured by Somsen (1).

Heat Capacity and Entropy

The heat capacities of CsF(cr) are estimated according to the method of Kristov (5), based on H°(976 K)-H°(298.15 K) = 9.4 kcal mol^{-1} reported by Dworkin (6). The entropy, S°(298.15 K), is estimated such that the calculated and observed vapor pressures are in good agreement (see CsF(g) and Cs_2F_2(g) tables for details).

Fusion Data

T_{fus} and $\Delta_{fus}H°$ are obtained from Bredig (7) and Dworkin (8). Buhalova (9) reported T_{fus} = 958 K, which is not adopted.

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ is calculated as the difference between $\Delta_f H°(298.15\ K)$ for CsF(g) and CsF(cr).

PREVIOUS: CURRENT: June 1968

$S°(298.15\ K) = [90.099]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 976\ K$

$\Delta_f H°(298.15\ K) = [-543.849]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 21.7\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(CsF, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(CsF, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(976\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Dworkin (1) measured the heat capacity of $CsF(\ell)$ at the melting point to be 17.7 cal K^{-1} mol^{-1} which is adopted and assumed to be constant in the temperature range 298-3000 K.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} = 1504 K is the temperature at which the calculated vapor pressures of CsF(g) and $Cs_2F_2(g)$ equal one atmosphere. The vapor composition at T_{vap} is calculated as CsF 80.3% and Cs_2F_2 19.7%. The enthalpy required to vaporize one mole of liquid to the above vapor mixture at T_{fus} is $\Delta_{vap} H°$.

T_{vap} has been observed as 1524 and 1526 K by Wartenberg (1) and Ruff (2), respectively, which are in fair agreement with the calculated one, 1504 K.

Enthalpy of Formation

The vapor pressures of CsF(cr) and CsF(ℓ) were measured by the manometric method by Wartenberg (1), Russ (2) and Cantor (3), the torsion-fiber effusion method by Pugh (4) and the Knudsen effusion method by Scheer (5). Based on the reported total pressures, the corresponding partial pressures of CsF(g) and $Cs_2F_2(g)$ were evaluated using the adjusted enthalpies of vaporization and Gibbs energy functions such that the calculated and observed total pressures are in reasonable agreement, and the derived enthalpy changes by the 2nd and 3rd law methods are consistent. The results obtained are presented in the table below. The value of $\Delta_f H^\circ$(CsF, g, 298.15 K) is adopted as -82.5 ± 0.5 kcal mol^{-1}.

The dissociation energy (D_0^0) of CsF(g) has been reported using the spectroscopic convergence limit as 5.65 eV (130.3 kcal mol^{-1}) and 5.5 eV (126.8 kcal mol^{-1}) by Herzberg (6) and Gaydon (9), respectively. Based on the above two D_0^0, and $\Delta_f H^\circ(0\ K)$ = 18.68 and 18.36 for Cs(g) and F(g), we obtain the corresponding value for $\Delta_f H^\circ$(CsF, g, 298.15 K) as -93.86 and -90.39 kcal mol^{-1}, which are not adopted.

Source	Reaction*	Method	$\Delta_r H^\circ$(298.15 K), kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H^\circ$(298.15 K), kcal mol^{-1}

(5)	A	Kundsen	48.43 ±0.27	46.61	-2.35 ±0.35	-85.96

Reactions: (A) CsF(cr) = CsF(g) (B) CsF(ℓ) = CsF(g).

Heat Capacity and Entropy

The ground state configuration was reported by Herzberg (6). The molecular constants are obtained from Honig et al (7), who observed the microwave spectra of CsF(g) at temperatures of about 700°C. Based on the J = 1 → 2 transition, the molecular constants are derived. The vibrational frequency (ω_e) has been reported, from different kinds of spectra, in the range 270-385 cm^{-1} by many investigators, e.g. radiofrequency, infrared, ultraviolet, microwave, etc. The value of ω_e adopted was reported by Baikov and Vasilevskii (8) who also reviewed the ω_e values obtained by the earlier investigators.

CESIUM HYDROXIDE (CsOH) CRYSTAL(ALPHA-BETA-GAMMA) M_r = 149.91274

$S°(298.15\ K) = [98.7 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$
$T_{trs1}(\alpha-\beta) = 410 \pm 1\ K$
$T_{trs2}(\beta-\gamma) = 493 \pm 1\ K$
$T_{fus} = 588 \pm 1\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -416.73 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = 1.30 \pm 0.13\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = 6.07 \pm 0.63\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 4.56 \pm 0.42\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of CsOH(cr) is obtained from the enthalpy of hydrolysis of metallic cesium, the enthalpy of solution of the hydroxide in water, and appropriate auxiliary data.

Beketov (1) and de Forcrand (2) determined the enthalpy of solution of crystalline CsOH in water. Parker (3) analyzed these data and selected $\Delta_{sol}H°(CsOH, cr) = -17.1 \pm 0.2\ kcal\ mol^{-1}$. This value is adopted here.

Discordant values for the enthalpy of hydrolysis of metallic cesium have been reported by Vorob'yev et al. (4) and Gunn (5). For the reaction $Cs(cr) + (n+1)\ H_2O(l) = CsOH{\cdot}n\ H_2O + 0.5\ H_2(g)$, they reported enthalpies of hydrolysis of -46.5±0.20 (n=1030) and -48.346±0.20 (n=3000) kcal mol^{-1}, respectively. From these values $\Delta_f H°(CsOH{\cdot}\infty H_2O, 298.15\ K) = -114.82 \pm 0.20$ and $-116.661 \pm 0.020\ kcal\ mol^{-1}$ are calculated based on $\Delta_f H°(H_2O, l, 298.15\ K) = -68.315\ kcal\ mol^{-1}$ (6).

In both investigations the possibility of hydroxide and oxide contamination of the metal samples was reduced by repeated distillation of the metal under vacuum, and spectroscopic analysis of each sample indicated low concentrations of the lighter alkali metals. Vorob'yev et al. (4) determined the amount of reaction by both weighing the metal sample and titrating the final hydroxide solution. Gunn (5) determined the amount of reaction by both weighing the sample and recovering the hydrogen formed in the hydrolysis. The systematically high hydrogen yields (0.05-0.16%) obtained by Gunn (5) suggest the presence of lighter alkali metals in higher concentrations than indicated by the spectroscopic analysis of the cesium, and the flame-photometric analyses of the final hydroxide solutions. However, the presence of lighter alkali metals at these concentrations should not introduce any serious error in the enthalpy of hydrolysis, since their heats (5) are quite similar to cesium.

The major difference between the two measurements lies in the instrumentation used to investigate the reaction. Vorob'yev et al. (4) used a hermetically sealed static calorimeter which was not stirred. In the absence of proper agitation, temperature gradients and chemical inhomogeneities are likely to arise in the final state. Without any indication of the performance of this calorimeter, the results of Vorob'yev et al. (4) are questionable. On the other hand, Gunn [5] carried out the hydrolysis reaction in a closed bomb calorimeter, agitation being effected by rocking the assembly through an angle of approximately 150° (5, 8). Where comparisons are possible, all indications are that the results are quite reliable. Therefore, we adopt $\Delta_f H°(CsOH{\cdot}\infty H_2O, 298.15\ K) = -116.661 \pm 0.020\ kcal\ mol^{-1}$ from the work of Gunn (5). Combining this result with the enthalpy of solution of CsOH(cr) given above, we derive $\Delta_f H°(CsOH, cr, 298.15\ K) = -99.6 \pm 0.2\ kcal\ mol^{-1}$ ($-416.73 \pm 0.8\ kJ\ mol^{-1}$).

Heat Capacity and Entropy

Heat capacities for CsOH(cr) over the entire temperature range 298-1000 K are estimated by comparison with similar data for the other alkali metal hydroxides and halides (9). Likewise, S°(298.15 K) is estimated to be 23.6 cal $K^{-1}\ mol^{-1}$ (98.7 J $K^{-1}\ mol^{-1}$) for CsOH(cr) by comparison with similar data for the alkali metal halides and lighter hydroxides (9).

Transition and Fusion Data

The temperatures and enthalpies of the polymorphic transitions and melting of CsOH(cr) are from the work of Reshetnikov and Baranskaya (10). These data were determined thermographically with $\Delta_{fus}H = 1.575\ kcal\ mol^{-1}$ for NaOH(cr) as a standard.

Sublimation Data

$\Delta_{sub}H°(298.15\ K)$ for the monomer and dimer are calculated from the adopted enthalpies of formation of the crystal and the respective gaseous species.

PREVIOUS: CURRENT June 1971

$S°$ (298.15 K) = [118.513] J K^{-1} mol^{-1}

T_{fus} = [illegible] ± 1 K

$\Delta_f H°(298.15\ K)$ = [-405.970] kJ mol^{-1}

$\Delta_{fus} H°$ = 4.56 ± 0.4 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°$(CsOH, ℓ, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(588 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ for liquid CsOH is estimated to be 19.5 cal K^{-1} mol^{-1} by comparison with similar data for the other liquid alkali metal hydroxides [1]. It is assumed constant in the temperature range 298-2000 K.

S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is calculated as the temperature at which $\Delta_r G°$ for the vaporization process is zero. The difference in the enthalpy of formation of CsOH(ℓ) and CsOH(g) at the boiling point is the heat of vaporization.

Cesium Hydroxide (CsOH) $Cs_1H_1O_1$(cr,l)

Vibrational Frequencies and Fundamentals

ν_i, cm^{-1}
335.6(1)
306 (2)
[3610](1)

Ground State Quantum Weight: 1

Point Group: $C_{\infty v}$

Bond Distances: Cs-O = 2.391 ± 0.002 Å O-H = [-0.96 ± 0.01] Å

Bond Angle: Cs-O-H = 180°

Rotational Constant: B_0 = 0.184795 cm^{-1}

Enthalpy of Formation

Jensen and Padley (1) determined an equilibrium constant for the reaction Cs(g) + H_2O(g) = CsOH(g) + H(g) at 2475 K by atomic absorption spectroscopy in a hydrogen-oxygen-nitrogen flame. These workers pointed out that interference from ionization of the metal had introduced some uncertainty in their equilibrium data. Using all JANAF functions (2), 3rd law analysis of the equilibrium constant gives $\Delta_r H°$(298.15 K) = 27.4 kcal mol^{-1}. This leads to an enthalpy of formation, $\Delta_f H°$(CsOH, g, 298.15 K) = -64.2±3.0 kcal mol^{-1}, and a corresponding bond dissociation energy of 91 kcal mol^{-1}. Cotton and Jenkins (3) investigated the same equilibrium in a fuel-rich hydrogen-oxygen-nitrogen flame and eliminated the ionization problem by working at a lower temperature (1570 K). 3rd law analysis of their equilibrium data gives $\Delta_r H°$(298.15 K) = 28.9 kcal mol^{-1} which results in $\Delta_f H°$(CsOH, g, 298.15 K) = -62.7±2.0 kcal mol^{-1} corresponding to D_0^0(Cs-OH) = 89.6 kcal mol^{-1}. Smith and Sugden (4) had earlier reported a D_0^0 = 91 ± 1 kcal mol^{-1} from flame studies. Electron impact studies (5, 6) have also led to values for the bond dissociation energy of CsOH(g). This method resulted in values of 82±3 (5) and 86±3 kcal mol^{-1} (6).

Cotton and Jenkins (3) also reported bond dissociation energies for LiOH(g), KOH(g), and NaOH(g) which are in good agreement with JANAF enthalpy of formation data (7) for these hydroxides. Furthermore, the position of the hydroxides in the order of increasing bond dissociation energy established from their data, i.e. NaOH < KOH < RbOH < CsOH < LiOH, is that predicted by comparison with similar data on the stabilities of the alkali metal halides (8). However, trends within the bond dissociation energies for the halides suggest that the value D_0^0 = 89.6 kcal mol^{-1} for CsOH may be slightly high. The difference in D° for potassium and sodium compounds is from 0.1 kcal mol^{-1} for the fluorides to 0.4 kcal mol^{-1} for the chlorides more than the difference in D_0^0 for the cesium and potassium compounds. Assuming this same trend in D_0^0 is prevalent in the hydroxides as well, then D_0^0(Cs-OH)-D (K-OH) must be less than 3.9 kcal mol^{-1}(see NaOH(g) table). We adopt D_0^0(CsOH) = 89.0±3.0 kcal mol^{-1} which results in the difference D_0^0(Cs-OH)-D_0^0(K-OH) = 3.6 kcal mol^{-1}(7). This adopted bond dissociation energy corresponds to $\Delta_f H°$(CsOH, g, 298.15 K) = -62.0±3.0 kcal mol^{-1}.

Heat Capacity and Entropy

The microwave spectra of gaseous CsOH have been studied in a high temperature spectrometer by Kuczkowski et al. (9) and Lide et al. (10). The spectroscopic data were more consistent with patterns expected from a linear molecule, although a "quasilinear" structure could not be completely eliminated. Acquista et al. (11) observed the infrared spectra of CsOH and CsOD in an argon matrix at liquid hydrogen temperatures. The isotope shift of the bending mode, ν_2, was quite large (80 cm^{-1}), and the ratio of ν_2 for CsOH and CsOD was in excellent agreement with the value calculated for a linear molecule and a harmonic oscillator. The infrared results when used in combination with the microwave data indicate a linear equilibrium configuration for CsOH. We adopt this configuration along with the bond distances and angles determined by Lide et al. (10) from their microwave data .

The Cs-O stretching mode, ν_1, and the bending frequency, ν_2, are from the matrix isolation studies of Acquista et al. (11). The OH stretching frequency, ν_3, is an estimate from the recent work of Jensen (12).

Rotational Constant: B_0 = [0.182583] cm^{-1}

Enthalpy of Formation

The appearance potential of $CsOH^+$ has been determined by Emel'yanov et al. (1) as 7.21±0.14 eV and by Gorokhov et al. (2) as 7.40±0.15 eV. These values correspond to $\Delta_r H°(0\ K)$ = 166.3±3.0 kcal mol^{-1} and 170.7±5 kcal mol^{-1}, respectively, for the process $e^- + CsOH(g) \rightarrow CsOH^+(g) + 2e^-$. Since there may be excess energy involved, we prefer the lower value. Combining this result with JANAF auxiliary data (3), we derive $\Delta_f H°(CsOH^+, g, 0\ K)$ = 105±10 kcal mol^{-1} (439.32 ± 41.8 kJ mol^{-1}).

Heat Capacity and Entropy

The correlation diagram of Walsh (4) for HAB molecules predicts that $CsOH^+$ (7 valence electrons) should be linear with the unpaired electron in a pi orbital. Therefore, we estimate the ground state of $CsOH^+$ to be $^2\Pi$. *$CsOH^+$ is isoelectronic with OH* (3) and SH (3). A first excited state is estimated at 32000 cm^{-1} to be $^2\Sigma$ by analogy with these isoelectronic molecules. The bonding in $CsOH^+$ is assumed to be weakened relative to that in CsOH by the loss of the bonding electron from the neutral species. The vibrational frequencies are estimated from those for CsOH with somewhat lower values due to the weaker bonding. The Cs-O and O-H bond distances are increased slightly over those for CsOH.

$\omega_e = [280]$ cm^{-1} $\omega_e x_e = [1.0]$ cm^{-1} $\sigma = 1$

$B_e = [0.198]$ cm^{-1} $\alpha_e = [0.001]$ cm^{-1} $r_e = [2.40]$ Å

Enthalpy of Formation

The enthalpy of formation is estimated from three calculated values. The methods of estimation are described as follows. Brewer and Margrave (1) suggested that the $\Delta_f H°$ value for MO(g) from the gaseous ions can be taken as the mean of the corresponding $\Delta_f H°$ values for the alkali fluoride and chloride with a maximum uncertainty of 10 kcal mol^{-1}. Adopting $\Delta_r H°(298.15\ K) = -131.1$ and -109.6 kcal mol^{-1} for the reaction $Cs^+(g) + F^-(g) = CsF(g)$ and $Cs^+(g) + Cl^-(g) = CsCl(g)$, respectively, we obtain $\Delta_r H°(298.15\ K) = -120.4$ kcal mol^{-1} for $Cs^+(g) + O^-(g) = CsO(g)$ which leads to $\Delta_f H°(CsO, g, 298.15\ K) = 12.0$ kcal mol^{-1}. The $\Delta_f H°(298.15\ K)$ values of the above species are taken from the respective JANAF Thermochemical Tables.

Based on the assumption that $D_0^0(Cs\text{-}O) = 1/2\ [D_0^0(Cs_2) + D_0^0(O_2)]$, we derive $D_0^0(Cs\text{-}O, g, 298.15\ K) = 65.2$ kcal mol^{-1} and $\Delta_f H°(298.15\ K) = 12.7$ kcal mol^{-1} for CsO(g).

Adopting the Cs-O bond energy as half of the atomization energy of Cs_2O, we calculate $D_0^0(Cs\text{-}O) = 60 \pm 10$ kcal mol^{-1} and $\Delta_f H°(CsO, g, 298.15\ K) = 17 \pm 10$ kcal mol^{-1}.

The enthalpy of formation for CsO(g) is tentatively selected as 15 ± 10 kcal mol^{-1}.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of the isoelectronic molecule OH(g). ω_e is estimated from those of LiO(g), CsF(g), and CsCl(g). The bond distance is taken from that in CsOH(g) reported by Lide and Kuczkowski (2). $\omega_e x_e$ is estimated by comparison with those of the other alkali oxides. The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3).

(d) $+9.2704 \times 10^{-13}(v + 1/2)^2 - 9.7917 \times 10^{-15}(v + 1/2)^3$ for $^1\Sigma_g^+$
(e) As determined from B_e

Enthalpy of Formation

Using the adopted value of the ground state dissociation energy for $Cs_2(g)$, D_0^0 = 43.389 kJ mol^{-1} (1), and the recommended $\Delta_f H°(Cs, g, 0\ K)$ = 155.160 kJ mol^{-1} from NBS (6), we calculate the adopted value of $\Delta_f H°(Cs_2, g, 0\ K)$ = 111.77 kJ mol^{-1}. This value is in essential agreement with the NBS recommended value of 111.7 kJ mol^{-1}. Correcting the adopted $\Delta_f H°(0\ K)$ to 298.15 K using the current value of $H°(298.15\ K)-H°(0\ K)$ = 11.029 kJ mol^{-1} for $Cs_2(g)$ and the NBS value of $H°(298.15\ K)-H°(0\ K)$ = 7.711 kJ mol^{-1} for Cs(cr) (6), we obtain $\Delta_f H°(Cs_2, g, 298.15\ K)$ = 107.38 kJ mol^{-1}.

Heat Capacity and Entropy

The heat capacity and entropy were calculated using a direct summation technique similar to the $Li_2(g)$ calculation (7) using ground state data from Raab et al (1), as recommended by Stwalley (2). Spectroscopic data for the $C^1\Pi_u$ state of $Cs_2(g)$ at T_e = 15949 cm^{-1} come from the work of Raab et. al. (4). The other low lying states of $Cs_2(g)$ are the $^3\Pi_u$ state at T_e = 7850 cm^{-1} (3), the $B^1\Pi_u$ state at 13044 cm^{-1} (5), and the $^1\Sigma_u^+$ state at T_e = 16720 cm^{-1} (4). These states have not been characterized satisfactorily to date. To include the excited states in the thermodynamic calculation in an approximate manner, we proceeded as with the $Na_2(g)$ species as follows (7). The $C^1\Pi_u$ state was included using the spectroscopic data reported by Raab (1). To account for the $^3\Pi_u$, $B^1\Pi_u$ and $^1\Sigma_u^+$ states, the rotational levels of the $C^1\Pi_u$ state were weighted x 13 to account for the sixfold degeneracy of the $^3\Pi_u$ state, the threefold degeneracy of each of the $^1\Pi_u$ states and the singly degenerate $^1\Sigma_u^+$ state. Note that the $^3\Sigma_u^+$ state is weakly bound and was neglected. Due to the minimal number of vibrational and rotational levels used by (1) to generate Dunham coefficients for the $C^1\Pi_u$ state, we artificially truncated the G(v) expression after the $\omega_e x_e$ term and the B(v) expression after the f_e term. For the same reason, we used Herzberg's method (see Li_2 table) to estimate D_e = 8.5833 x 10^{-9} cm^{-1} rather than use the value of (1).

As with the $Na_2(g)$ calculation, the above method certainly underestimates the $^3\Sigma_u$ and $B^1\Sigma_u$ contributions but at the same time overestimates the $^1\Sigma_u^+$ contribution to the thermodynamic functions. The contribution of the excited states to the free energy function is negligible at temperatures below 2000 K and only contribute ca. 0.25 J K^{-1} mol^{-1} at 6000 K. This method of treating the excited states does result, however, in a more realistic high temperature heat capacity. The rotational levels of the ground state were weighted in accordance with the nuclear spin of the atom (I = 7/2): even J weight = .5833, odd J weight = .4167. The adopted value of S°(298.15 K) is larger than the NBS adopted value (6) by 0.74 J K^{-1} mol^{-1} but is in exact agreement with that adopted by Gurvich, et al. (8).

Enthalpy of Formation

Evidence from the velocity distribution in molecular beams (1) has shown that alkali halide vapors contain significant amounts of polymeric species. Using the same method Eisenstadt (2) determined the molecular composition of CsF vapor in the temperature range 838-919 K. *Based on the reported equilibrium constants for the reaction* $(CsF)_2(g) = 2CsF(g)$, we evaluate the enthalpy change, $\Delta_r H°(298.15\ K)$, by the 2nd and 3rd law methods to be 40.53±1.75 and 42.34±0.26 kcal mol^{-1}, respectively. Employing $\Delta_r H°(298.15\ K) = 42.34$ and $\Delta_f H°(CsF, g, 298.15\ K) = -85.2$ kcal mol^{-1}, we obtained $\Delta_f H°(298.15\ K) = -212.74$ kcal mol^{-1} (-890.10±8.4 kJ mol^{-1}) for $Cs_2F_2(g)$, which is adopted.

Heat Capacity and Entropy

The Cs_2F_2 molecule is assumed to have a rhombic configuration of symmetry D_{2h} as Cs_2Cl_2(3). The Cs-F bond distance is taken as the same as that in CsF(g). The bond angles and vibrational frequencies are estimated by comparison with those of the other dimeric alkali halides (3, 4). *The principal moments of inertia are:* $I_A = 15.9040 \times 10^{-39}$, $I_B = 132.5032 \times 10^{-39}$ and $I_C = 148.4071 \times 10^{-39}$ g cm^2.

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_{2h}
Bond Distances: Cs-O = [2.63] Å O-H = [0.96] Å
Bond Angles: Cs-O-Cs = [90]° Cs-O-H = [110]°
Product of Moments of Inertia: $I_A I_B I_C$ = [5.396347 x 10^{-112}] $g^3\ cm^6$

Enthalpy of Formation

Schoonmaker and Porter (1) analyzed the vapors in equilibrium with liquid CsOH and mixed KOH-CsOH condensed phases with a mass spectrometer and reported the presence of appreciable concentrations of dimer in the temperature range 650-700 K. By applying the method of relative equilibrium constants, these workers calculated the difference in the free energies of dimerization for KOH-CsOH. A 3rd law analysis of their free energy data for this pair leads to a difference in the enthalpies of dimerization of 4.9 kcal mol^{-1} at 298.15 K for CsOH and KOH. Based upon the adopted value for KOH(g), $\Delta_f H°$(dimerization, 298.15 K) = -45.3±3.0 kcal mol^{-1} (2), we derive $\Delta_f H°$(dimerization, 298.15 K) = -40.4±4.0 kcal mol^{-1} for 2 CsOH(g) = $Cs_2(OH)_2$(g). Combining this result with the enthalpy of formation for the gaseous monomer (3), that for the dimer is $\Delta_f H°(Cs_2(OH)_2, g, 298.15\ K)$ = -164.4±10.0 kcal mol^{-1} (-687.8±41.8 kJ mol^{-1}).

Heat Capacity and Entropy

Buchler et al. (4) investigated the geometries of several molecules containing cesium by the deflection of molecular beams in an inhomogeneous electric field. Their results for $Cs_2(OH)_2$(g) indicated that the molecule was nonpolar which implies a planar configuration for at least the Cs_2O_2 part of the molecule. Several structural models proposed for the dimers of the *alkali metal hydroxides each incorporate this planar configuration for the alkali and oxygen atoms. Bauer et al. (5)* calculated entropies of dimerization for NaOH(g) and KOH(g) with a dimer model consisting of a square planar configuration for the alkali and oxygen atoms with two hydrogen bonded bridges between the oxygens and hydrogens. Schoonmaker and Porter (1) adopted the same alkali-oxygen configuration but did not allow for hydrogen bonding between the oxygens and hydrogens. Berkowitz et al. (6) relied on the apparent similarity of the alkali halides and hydroxides in forming dimeric species to propose a structural model for $Li_2(OH)_2$(g). This model consisted of a trans-configuration with hydrogens above and below the plane of a rhombus formed by the lithium and oxygen atoms, the Li-O-Li bond angle being 100°. We adopt a structure for $Cs_2(OH)_2$(g) which is similar to the model of Berkowitz et al. (6) for $Li_2(OH)_2$(g) but with the Cs-O-Cs bond angle equal to 90°. The cesium and oxygen atoms form a square planar configuration. The Cs-O-H bond angle is assumed equal to 110°. The Cs-O bond distance is estimated as being 10% longer than that in CsOH(g). The O-H bond distance is estimated to be the same as in H_2O(g). The principal moments of inertia are: I_A = [20.4212] x 10^{-39}, I_B = [152.8696] x 10^{-39}, and I_C = [172.8610] x 10^{-39} g cm^2.

Acquista et al. (7) observed the infrared spectra of matrix isolated CsOH and reported bands in the region 300-200 cm^{-1} *whose relative intensities decreased with increasing temperature. Since the dimer to monomer ratio decreases with increasing* temperature, these bands appeared to arise from polymeric species of CsOH, but no definite assignments could be made. Similar results have been reported for RbOH and NaOH from infrared studies (8) of these molecules trapped in inert matrices. Berkowitz et al. (6) estimated vibrational frequencies for $Li_2(OH)_2$(g) by comparison with those for dimeric Li_2F_2(g). The frequencies for Li_2F_2(g) had been estimated earlier by Berkowitz (9) using an ionic model and normal coordinate analysis. It has now been established experimentally that these estimated frequencies for Li_2F_2(g) are too low (See Li_2F_2(g) table for details). Until definite assignments for the dimer hydroxides can be made from infrared studies, we tentatively adopt the six estimated frequencies for Cs_2F_2(g) (See CsF_2(g) table for details) and apply them directly to $Cs_2(OH)_2$(g). The remaining O-H stretching and bending frequencies are estimates from the work of Berkowitz et al. (6).

Enthalpy of Formation

The appearance potentials of CsOH and Cs_2O ions were investigated by Emel'yanov et al. (1), using the electron-impact method with a mass spectrometer fitted with a heated ion source and a Pt effusion chamber. The enthalpy of atomization of Cs_2O was derived as 117±10 kcal mol^{-1}. Based on this value we calculate the enthalpy of formation $\Delta_f H°(298.15\ K)$ of Cs_2O to be -22±10 kcal mol^{-1} (-92.0±41.8 kJ mol^{-1}), employing $\Delta_f H°(0\ K)$ = 18.68 and 58.99 kcal mol^{-1} for Cs(g) and O(g), respectively. Brewer and Mastick (2) calculated theoretically the stability of gaseous alkali oxides according to ionic models and gave the enthalpies of formation from gaseous atoms for $Cs_2O(g)$ as -24 kcal mol^{-1}. The $\Delta_f H°(298.15\ K)$ value is evaluated to be 72.2 kcal mol^{-1} which is not adopted.

Heat Capacity and Entropy

The molecular structure of $Cs_2O(g)$ has been determined to be nonlinear by Buchler et al. (3), using electric-deflection method. The Cs-O bond distance is assumed to be the same as that in CsOH(g) reported by Lide and Kuczkowski (4). The bond angle is estimated by comparison with that in the H_2O molecule. Three vibrational frequencies are estimated from those for $H_2O(g)$. The principal moments of inertia are: I_A = 5.3492 x 10^{-39}, I_B = 160.0237 x 10^{-39}, and I_C = 165.3730 x 10^{-39} g cm^2.

CESIUM SULFATE, I (Cs_2SO_4, I) CRYSTAL(I) M_r = 361.8684

$S°(298.15\ K) = [264.834]\ J\ K^{-1}\ mol^{-1}$
$Tt(II+I) = 940 \pm 5\ K$
$T_{fus}(I+\ell) = 1278 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-1410.152]\ kJ\ mol^{-1}$
$\Delta_{trs}H°(II+I) = 4.310 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_{fus}H°(I+\ell) = 35.690 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Cs_2SO_4$, cr, I, 298.15 K) is calculated from $\Delta_f H°(Cs_2SO_4$, cr, II, 298.15 K) by adding the enthalpy of transition (II+I) and the difference in enthaply, H°(940) - H°(298.15 K), between the II and I crystalline forms (1).

Heat Capacity and Enthalpy

High-temperature enthalpies of the I-phase of Cs_2SO_4 have been determined by Denielou et al. (2, 960-1260 K) and by Polischcuk et al. (3, 950.7-1254.5 K). We have adopted heat capacities based upon the enthalpies of Denielou et al. (2). We have extrapolated the heat capacities smoothly to 298.15 K below the II+I transition and extended $C_p°$ above the melting point to 1500 K.

S°(298.15 K) is calculated in a manner similar to that used for the enthalpy of formation.

Transition Data

The high-temperature hexagonal modification of cesium sulfate is denoted Cs_2SO_4, cr, I, in accordance with the usual nomenclature. This modification has been referred to as the α-phase in contrast to our use of α to refer to the low-temperature phase for the other members of the alkali metal sulfates (1).

Fusion Data

The adopted melting point, T_{fus} = 1278±5 K, was determined from the work of Denielou et al. (2, 1274±3 K), Polishchuk et al. (3, 1281 K), Rassonskaya and Semendyaeva (4, 1283 K), and from the compilation of Stern and Weise (5, 1277 K). The enthalpy of fusion, $\Delta_{fus}H°$ = 8.530±0.2 kcal mol^{-1}, is calculated from the difference between the smoothed relative enthalpy of the liquid and the adopted enthalpy value for the I form at T_{fus}.

Enthalpy of Formation

The enthalpy of solution at infinite dilution of Cs_2SO_4 has been measured by Kuznetsova et al. (1, 3.980 kcal mol^{-1}) and by Borob'ev et al. (2, 4.11±0.80 kcal mol^{-1}). We adopt the mean of these values 4.05±0.1 kcal mol^{-1}. When this result is combined with enthalpies of formation of the infinitely dilute ions from CODATA (3), we obtain $\Delta_f H^\circ(Cs_2SO_4, \infty H_2O, 298.15\ K)$ = -340.746±0.12 kcal mol^{-1} and $\Delta_f H^\circ(Cs_2SO_4, cr, 298.15\ K)$ = -344.80±0.2 kcal mol^{-1}.

Heat Capacity and Entropy

The low temperature heat capacities of Cs_2SO_4 were measured by Paukov et al. (4) by adiabatic calorimetry over the region 12.82-308.72 K. The curve of Cp-T was graphically extrapolated to 0 K. Our adopted value of S°(298.15 K) = 50.64±0.05 cal K^{-1} mol^{-1} is based on S°(12 K) = 0.309 cal K^{-1} mol^{-1} as estimated by Paukov et al. (4). They also estimated H°(12 K)-H°(0 K) = 2.83 cal K^{-1} mol^{-1} which leads to H°(298.15 K)-H°(0 K) = 6.628±0.006 kcal mol^{-1}. These values of S°(12 K) and H°(12 K)-H°(0 K) are almost identical to estimates obtained using a Debye T^3-law extrapolation. We have smoothed the experimental data of Paukov et al. (4) by fitting to orthogonal polynomials.

High temperature heat capacities of Cs_2SO_4 have been measured by Shmidt (5) by adiabatic calorimetry over the range 297.5-774.0 K. Enthalpy measurements by drop calorimetry were carried out by Denielou et al. (6, 400-910 K) and by Polishchuk et al. (7, 803.3-933.4 K). We have joined the low temperature C_p° data of Paukov (4) to the high temperature C_p° data of Shmidt (5) and then merged this into C_p° values derived from the measurements of Denielou et al. (6) above 700 K. We have extrapolated the data smoothly to 1200 K.

Transition Data

Cs_2SO_4(cr, II) is the low-temperature form of cesium sulfate (often denoted as Cs_2SO_4, β). The crystals are orthohombic, space group D_{2h}^{16}-Pmcn (8). The transformation to the high-temperature I-phase (hexagonal, Cs_2SO_4, I) occurs at 940±5 K (5, 6, 7). The enthalpy of transition is determined by taking the difference between the adopted enthalpy curves of II- and I-Cs_2SO_4 extended to 940 K.

CESIUM SULFATE (Cs_2SO_4) LIQUID M_r = 361.8684

$S°(298.15\ K) = [246.449]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}(I \rightarrow \ell) = 1278 \pm 5\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-1400.139]\ kJ\ mol^{-1}$

$\Delta_{fus} H°(I \rightarrow \ell) = 35.690 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Cs_2SO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Cs_2SO_4, cr, I, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1278) - H°(298.15\ K)$, between the I crystal and liquid (1).

Heat Capacity and Entropy

Enthalpies for $Cs_2SO_4(\ell)$ have been measured by Denielou et al. (2) and by Polishchuk et al. (3). We adopt enthalpies based on the work of Denielou et al. (2). This leads to a constant heat capacity of 49.4 cal $K^{-1}\ mol^{-1}$ at temperatures above an assumed glass transition at 780 K. Below the glass transition, the heat capacity is taken as that of the low temperature II phase.

$S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the *I*-crystal table for details.

Ground State Quantum Weight: 1 σ = 4

Point Group: D_{2d}

Bond Distances: S-O = 1.49±0.02 Å Ca-O = 2.60±0.07 Å

Bond Angles: O-S-O = 109.47° O-Ca-O = 55±5°

Product of the Moments of Inertia: $I_A I_B I_C = 3.287254 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

Vaporization experiments on Cs_2SO_4 have been carried out by Ficalora et al. (1), Cubicciotti (2), Gorokhov and Efimova (3), and Jaganathan and Wyatt (4). Cubicciotti (2) carried out Langmuir sublimation experiments which showed that Cs_2SO_4(cr, I) vaporizes congruently and the predominant vapor species is Cs_2SO_4(g). The Knudsen effusion experiments of Cubicciotti (2) are in excellent agreement with the mass spectrometric and effusion data of Gorokhov and Efimova (3). The Knudsen weight loss results of Jagannathan and Wyatt (4) are in good agreement with the previous studies (2, 3) but the data show a substantial drift. The mass spectrometric study of Ficalora et al. (1) yields vapor pressures which are much lower than results of the other three studies. The adopted value of the enthalpy of formation, $\Delta_f H°(Cs_2SO_4, g, 298.15\ K) = -268.3 \pm 4.0\ kcal\ mol^{-1}$, is based on JANAF analyses of the vaporization data given below. The calculated 3rd law $\Delta_r H°(298.15\ K)$ *may have an uncertainty of* 4 kcal mol⁻¹ since the JANAF Gibbs energy functions are partially based on the estimated molecular constants of Cs_2SO_4(g).

Source	Method	T/K	Data Points	δS cal K⁻¹ mol⁻¹	$\Delta_r H°(298.15\ K)$, kcal mol⁻¹ 2nd law	3rd law	$\Delta_f H°(298.15\ K)$ kcal mol⁻¹

Reaction: $Cs_2SO_4(cr) = Cs_2SO_4(g)$

Heat Capacity and Entropy

The structure of cesium sulfate is based on the high temperature electron diffraction studies of Ugarov et al. (5) and of Spiridonov and Lutoshkin (6). These studies show a fairly rigid tetrahedral sulfate anion core but with highly mobile cesium atoms as evidenced by the very large amplitudes of vibration, ℓ(CsS) = 0.15 Å, ℓ(CsO) = 0.34 Å, (5). The average structure is of D_{2d} symmetry and can be pictured as having a central sulfur atom surrounded at the corners of a tetrahedron by four oxygen atoms with bridging cesium atoms between two pairs of oxygen atoms. The planar CsO_2S rings are mutually perpendicular. The principal moments of inertia are: $I_A = 15.7294 \times 10^{-39}$ and $I_B = I_C = 457.1516 \times 10^{-39}\ g\ cm^2$.

Belyaeva et al. (7) investigated the infrared absorption spectra (400-1500 cm⁻¹) of cesium sulfate molecules stabilized in matrices of Ne, Ar, Xe, and H_2 at 4.2 K. The bands listed above at 607, 628, 1100, and 1125 cm⁻¹ are from this work. In a later work, Belyaeva et al. (8) reported the low frequency (30-1500 cm⁻¹) infrared spectra of K_2SO_4, Rb_2SO_4, and Cs_2SO_4 molecules isolated in matrices of Ar, Kr, and Xe. The bands listed above at 160 and 140 cm⁻¹ are from this work. The band estimated at 40 cm⁻¹ is based on our upward adjustment of the calculation of Belyaeva et al. (8, 9). The band estimated at 970 cm⁻¹ is based on the Raman work of Atkins and Gingerich (10) on the similar molecules K_2SO_4 and Na_2SO_4. The remaining fundamental frequencies are estimated by analogy with the other alkali metal sulfates (11).

Copper (Cu) Cu_1(ref)

$S°(298.15\ K) = 33.164 \pm 0.04\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1358.0 \pm 0.2\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 13.138 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacity and entropy of copper have been well established by the critical review of Furukawa et al. (1). Their recommended smoothed values are adopted with minor corrections for a change in the relative atomic mass from 63.54 to 63.546 (2) and for a change to the International Practical Temperature Scale of 1968 (3). These corrections increase the entropy at 298.15 K from 7.923 to 7.926 cal K^{-1} mol^{-1} and the enthalpy difference, H°(298.15 K) − H°(0 K), from 1.1962 to 1.1967 kcal mol^{-1}. The values recommended by CODATA (4) are those of Furukawa (1).

From 300 K to the melting point, the heat capacity selected by Hultgren et al. (5) has been adopted, with correction for relative atomic mass and temperature scale, and has been joined smoothly with the adopted low temperature data. The measurements of Chekhovskoi and Gerasina (6), as given by their equation (300-900 K), are in excellent agreement with the selection of Hultgren et al. (5). Also, while the data given by Brooks et al. (313-1193, 7) were 1 to 2% higher than Hultgren's selected values, the later measurements of Yeh and Brooks (8) on the same sample did not totally confirm the earlier results and measurements on a larger sample (370-870 K) are in good agreement with Hultgren et al. (5). The same evaluation used by Hultgren et al. (5) is used by two other tabulations (9, 10), although there are small differences in the tabulated values.

Fusion Data

Righini et al. (11) reviewed the precise measurements of the freezing point of high-purity copper made since 1960. The mean value of five investigations is 1357.99±0.24 (IPTS-68). N. N. Ergardt (12) found 1358.41 K and Righini et al. (11) measured 1357.98±0.1 K. We adopt 1358.0±0.2 K for the melting point. As a secondary fixed point IPTS-68 uses 1357.6 K (13).

The adopted value for $\Delta_{fus}H°$ is based upon five measured values and an evaluation of H°(1358 K) − H°(298.15 K) for the solid and the liquid.

Source	$\Delta_{fus}H°$, kcal mol^{-1}
(14)	3.239
(15)	3.030
(16)	3.080
(17)	3.290±0.275
(18)	3.107±0.048

The average is 3.149 kcal mol^{-1}. Our least squares linear fit of the liquid enthalpy data of Wust, Meuthen, and Durrer (14) leads to $\Delta_{fus}H° = 3.139$ kcal mol^{-1}, and with this change, the average of the five measured values is 3.129 kcal mol^{-1}.

We adopt $\Delta_{fus}H° = 3.140 \pm 0.1$ kcal mol^{-1}.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: DEcember 1965 CURRENT: June 1977

$S°(298.15\ K) = [41.620]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1358.0 \pm 0.2\ K$

$\Delta_f H°(298.15\ K) = [11.857]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 13.138 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation at 298.15 is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1358 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Since the critical evaluation of Hultgren et al. (1) and the selection of 7.80 cal K^{-1} mol^{-1} for the heat capacity of liquid copper, there have been two experimental investigations. Chaudhuri et al. (2) measured enthalpies (1386-1887 K) by levitation-heating aluminum-block drop calorimetry and determined Cp(ℓ) = 7.89±0.41 cal K^{-1} mol^{-1}. Stephens (3) found Cp(ℓ) = 8 cal K^{-1} mol^{-1} by levitation-heating liquid-argon calorimetry (1428-2007 K). The scatter in the new liquid argon calorimetry data is large and is considered only in that it tends to support a "chronological increase" in Cp(ℓ) of copper. The enthalpy differences, H°(1358 K) - H°(298.15 K), derived from the measurements of Vollmer and Kohlhaus (4) and Chaudhuri et al. (2) are in good agreement at about 10.228 kcal mol^{-1}, which we adopt. The scatter of liquid enthalpy measurements easily accommodates a wide range of values for Cp(ℓ); we adopt 7.85 cal K^{-1} mol^{-1}, an average of the value selected by Hultgren et al. (1) and the later measurement of Chaundhuri et al. (2). This value is assumed constant from 900 to 4000 K. A glass transition is assumed at 900 K below which the heat capacity is tha of the crystal.

The entropy is calculated in a manner similar to that used to calculate the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is the calculated temperature at which the Gibbs energy difference is zero for the reaction Cu(ℓ) = Cu(g). $\Delta_{vap}H°$ is the difference in $\Delta_f H°$ between gas and liquid at T_{vap}.

Enthalpy of Formation

The adopted enthalpy of formation for Cu(g), $\Delta_f H°(298.15\ K)$ = 337.6 ± 1.2 kJ mol^{-1}, is the value recommended by CODATA (1). This value was based on the measurements of Edwards et al. (2), Hersh (3), Morris and Zellars (4), Marshall et al. (5), McCormack et al. (6), Myles and Darby (7), Grieviso et al. (8), Kirschenbaum and Cahill (9), Krupkowski and Golonka (10) and Ponslit and Bariaux (11). Additional references are given in Hultgren et al. (12).

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (13), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground state and the lowest lying levels, all levels listed by Moore (13), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for Cu(g), the thermodynamic functions are independent of the estimated missing levels (for n=4-11), the cut-off procedure, and the inclusion of n<12 levels up to 6000 K; the Gibbs energy function showing variations of 0.001 J K^{-1} mol^{-1} at this temperature. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>11), and use of different fill and cut-off procedures (14).

COPPER, ION (Cu^+) IDEAL GAS M_r = 63.54545

$IP(Cu^+, g)$ = 163669.2 ± 0.5 cm^{-1}

$S°(298.15\ K)$ = 222.311 ± 0.02 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 1081.9 ± 2.1 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [1089.277] kJ mol^{-1}

Electronic Levels and Quantum Weights

State	ε_i cm^{-1}	g_i
$^1S_0$	0.0	1
$^3D_0$	21928.60	7
$^3D_1$	22847.03	5
$^3D_1$	23998.31	3
$^1D_2$	26264.52	5

Enthalpy of Formation

$\Delta_f H°(Cu^+, g, 0\ K)$ is calculated from $\Delta_f H°(Cu, g, 0\ K)$ (1) using the spectroscopic value of IP(Cu) = 62317.2 ± 0.5 cm^{-1} (745.479 ± 0.006 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Cu^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Cu, g, 0\ K)$ by using IP(Cu) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Cu(g), $Cu^+(g)$, and $e^-(g)$. $\Delta_f H°(Cu \rightarrow Cu^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoretically predicted levels that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states. The next excited state is 66418.65 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

EA(Cu, g) = 1.228 ± 0.010 eV

$S°(298.15\ K) = 160.634 \pm 0.001\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 217.926\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [212.920]\ kJ\ mol^{-1}$

Electonic Level and Quantum Weight

State	ϵ_i, cm^{-1}	g_i
$^1S_0$	0.0	1

Enthalpy of Formation

$\Delta_f H°(Cu^-, g, 0\ K)$ is calculated from $\Delta_f H°(Cu, g, 0\ K)$ (1) using the adopted electron affinity of EA(Cu) = 1.228 ± 0.010 eV (118.483 ± 0.965 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment election spectrometry study (3). Additional information on $Cu^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Cu^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Cu, g, 0\ K)$ by using EA(Cu) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Cu^-(g)$, Cu(g), and $e^-(g)$. $\Delta_r H°(Cu^- \rightarrow Cu + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Cu^-(g)$ is given by Hotop and Lineberger (2, 4) and Rosenstock et al. (5). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

$S°(298.15\ K) = [64.852 \pm 2.1]\ J\ K^{-1}\ mol^{-1}$
T_{fus} = Unknown

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = [-280.33 \pm 41.8]\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The enthalpy of formation is calculated by combining the adopted $\Delta_f H°(CuF, g, 298.15\ K) = -3.0 \pm 4\ kcal\ mol^{-1}$ with the estimated enthalpy of sublimation of 64 kcal mol^{-1}. A comparison of enthalpies of sublimation of LiF with LiCl, NaF with NaCl, and KF with KCl (1) along with an enthalpy of sublimation of CuCl of 54.77 kcal mol^{-1} (1) indicates that $\Delta_{sub} H°(CuF, cr, 298.15\ K)$ might be in the range of 58 to 71 kcal mol^{-1}. The tabulations of King et al. (2) lead to $\Delta_{sub} H°(298.15\ K)$ = 64 kcal mol^{-1} which we adopt. We derive $\Delta_f H°(CuF, cr, 298.15\ K) = -67 \pm 10\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

We adopt the heat capacities estimated by King et al. (2) and $S°(298.15\ K) = 15.5 \pm 0.5\ kcal\ mol^{-1}$ estimated by (3).

Enthalpy of Formation

Hildenbrand (1) and Ehlert and Wang (2) have reported mass spectrometric measurements of equilibrium pressures of the reactions MgF(g) and Cu(g) = Mg(g) + CuF(g) and 1/2 CuF_2(cr) + 1/2 Cu(cr) = CuF(g), respectively. Our 2nd and 3rd law analyses follow.

Source	Reaction*	T/K	Data Points	$\Delta_r H°(298.15\ K)$, $kcal\ mol^{-1}$ 2nd law	3rd law	Drift $cal\ K^{-1}\ mol^{-1}$	$\Delta_f H(298.15\ K)$ $kcal\ mol^{-1}$
(1)	A	1413-1590	12	11.52±2.84	7.08±0.68	-2.9±1.9	-4.15±3
(2)	B	936-948	3	75.97±3.90	62.34±0.19	-14.5±4.1	-2.06±21

*Reactions: A) MgF(g) + Cu(g) = Mg(g) + CuF(g) (B) 1/2 CuF_2 + 1/2 Cu(cr) = CuF(g)

We adopt the rounded average, $\Delta_f H°(CuF, g, 298.15\ K) = -3.0 \pm 4\ kcal\ mol^{-1}$ ($-12.552 \pm 16.7\ kJ\ mol^{-1}$), which leads to D_0^0(Cu-F, 298.15 K) = 102.5±5 $kcal\ mol^{-1}$ and D_0^0(Cu-F) = 101.7±5 $kcal\ mol^{-1}$ (425.513 ± 20.9 $kJ\ mol^{-1}$).

Another value extant in the literature is $D_0^0(298.15\ K) = 83.6 \pm 4.0\ kcal\ mol^{-1}$ estimated from the heat of atomization of CuF_2, derived from sublimation studies, and the ratio $D_0^0(M-F)/\Delta_a H°(MF_2) = 0.46$ (4). Hildenbrand (1) has discussed the valence-state concept which predicts that $D_0^0(M-F) > D_0^0(MF-F)$; therefore the ratio $D_0^0(M-F)/[D(M-F) + D_0^0(MF-F)$ must be greater than 0.5. With $\Delta_{at}H°(CuF_2, 298.15\ K) = 182.17\ kcal\ mol^{-1}$ (3) and D_0^0(Cu-F, 298.15 K) = $-102.5\ kcal\ mol^{-1}$, the ratio based on JANAF values is 0.56. For $\Delta_{at}H°(CuF_2, 298.15\ K) = 182.7\ kcal\ mol^{-1}$, D_0^0(Cu-F, 298.15 K) must be greater than 91.08 $kcal\ mol^{-1}$ to agree with the valence-state concept.

Other calculations by Kent et al. (4) give D (298.15 K) values ranging from 84.4 to 94.5 $kcal\ mol^{-1}$. Gaydon (5) recommends $D_0^0 = 81\ kcal\ mol^{-1}$ from a linear Birge-Sponer extrapolation of spectroscopic data but suggests that it is probably higher. King et al. (6) used $\Delta_f H°(298.15\ K) = 14\ kcal\ mol^{-1}$, $\Delta_{at}H°(298.15\ K) = 84.7\ kcal\ mol^{-1}$ in their recent tabulation.

Heat Capacity and Entropy

The values of B_e, α_e and r_e are from the microwave data of Hoeft et al. (7) adjusted for normal isotopic abundance; the electronic levels, ω_e and $\omega_e x_e$ are taken from Rosen (8).

PREVIOUS: December 1977 (1 atm) CURRENT: December 1977 (1 bar)

$S°(298.15\ K) = 77.452 \pm 0.08\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1109 \pm 10\ K$

$\Delta_f H°(0\ K) = -537.2 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -538.9 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 55.229 \pm 20.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Pervov et al. (1) *have measured a enthalpy of formation of* -128.8 ± 0.3 kcal mol^{-1} by direct fluorine combustion calorimetry. In view of the spread of values obtained from the equilibrium pressure and the emf data discussed below, we adopt $\Delta_f H°(CuF_2, cr, 298.15\ K) = -128.8 \pm 2$ kcal mol^{-1} (-538.899 ± 8.4 kJ mol^{-1}).

Jellinek and Rudat (2) and Domange (3) have measured equilibrium partial pressures for reactions of CuF_2(cr) with hydrogen and with water, respectively. Koerber and De Vries (4) and Skelton and Patterson (5) have derived $\Delta_r G°$ from emf studies. Our 2nd and 3rd law analyses are as follows, using auxiliary data from the JANAF Thermochemical Tables (6).

Source	Reaction*	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(2)	A	423	1	--	22.6	--	-152.9
(3)	B	573-723	4	23.3±1.3	20.8±0.6	-3.9±2.0	-130.6±2
(4)	C	273-283	2	-1.9	-10.6±0.4	-31.4	-126.6±4
(5)	D	661-918	Equation	-132.1	-136.4	-5.5	-136.4

*Reactions: (A) $CuF_2(cr) + H_2(g) = Cu(cr) + 2\ HF(g)$ (C) $Cu(cr) + Hg_2F_2 = CuF_2(cr) + 2\ Hg(\ell)$

(B) $CuF_2(cr) + H_2O(g) = CuO(cr) + 2\ HF(g)$ (D) $Cu(cr) + F_2(g) = CuF_2(cr)$

The evaluation of King et al. (7), $\Delta_f H°(CuF_2, cr, 298.15\ K) = -130.2$ kcal mol^{-1}, preceded the direct fluorination study of Pervov et al. (1) and is based *mainly on the work of Domange* (3) and Koerber and De Vries (4). We place greater reliance on the direct fluorination work (1).

Heat Capacity and Entropy

The heat capacity is based on smoothed values from the unpublished low temperature measurements of Boo and Stout (8, 10-300 K) and the differential scanning calorimetric measurements of heat capacity by Ehlert (9, 300-710 K). Our graphical joining and smoothing of the two data sets produces data which are 1 to 2% lower than Ehlert's measurements (9) in the 350-500 K range and are in agreement from 520-700 K; our extrapolation *to 1000 K yields 21.60* cal K^{-1} mol^{-1} compared to 22.4 cal K^{-1} mol^{-1} by Ehlert (9).

Boo and Stout (8) show an anomaly in the heat capacity at 70.90 K. $S°(298.15\ K) = 18.51$ cal K^{-1} mol^{-1} is based on $S°(10\ K) = 0.009$ cal K^{-1} mol^{-1} by Boo and Stout (8).

Fusion Data

Ehlert and Wang (10) interpret their DTA measurements as indicating a solid state transition at 1065±10 K and a fusion point of 1109±10 K. They believe the observed transitions at 1028 K and 1040 K are caused by Cu_2O-CuF_2 and 10 CuO_2-20Cu-70CuF_2 weight percent eutectics, respectively. Based on the latter, and ignoring the 1065 K solid state transition, they calculate a heat of fusion of 13.2±2 kcal mol^{-1}. We adopt $T_{fus} = 1109 \pm 10$ K and $\Delta_{fus} H° = 13.2 \pm 5$ kcal mol^{-1} and await confirmation of the solid state transition.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: June 1966 CURRENT: December 1977

COPPER FLUORIDE (CuF_2) LIQUID M_r = 101.542806

$S°(298.15\ K)$ = [122.585] J K^{-1} mol^{-1}

T_{fus} = 1109 ± 10 K

$\Delta_f H°(298.15\ K)$ = [-487.854] kJ mol^{-1}

$\Delta_{fus} H°$ = 55.229 ± 20.1 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(CuF_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1109\ K) - H°(298.15\ K)$, between the crystal and the liquid.

Heat Capacity and Entropy

The heat capacity is estimated from an average heat capacity of 8 cal K^{-1} g-atom^{-1} for several difluorides and dichlorides. A glass transition is assumed at 740 K below which the heat capacity is that of the crystal.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} = 1948.9 K is the calculated temperature at which the fugacity of $CuF_2(g)$ is 1 atm for the reaction $CuF_2(\ell) = CuF_2(g)$. $\Delta_{vap} H°$ = 81.132 kJ mol^{-1} is the difference in $\Delta_f H°$ between gas and liquid at T_{vap}.

782 (1)

Ground State Quantum Weight: [2] $\sigma = 2$

Point Group: C_{2v}

Bond Distance: Cu-F = [1.72] Å

Bond Angle: F-Cu-F = 165 ± 8°

Product of the Moments of Inertia: $I_A I_B I_C = [6.77288 \times 10^{-116}]\ g^3\ cm^6$

Enthalpy of Formation

Sublimation pressures, $CuF_2(cr) = CuF_2(g)$, have been measured by Kent et al. (1, 897-1026 K) and by Ehlert and Wang (2, 874-1005 K) by effusion cell-mass spectrometric techniques. Using JANAF data (6) for $CuF_2(cr)$, we derive the following by 2nd and 3rd law analysis:

Source	T/K	Data Points	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°$(cr, 298.15 K), kcal mol^{-1}
(1)	897-1026	26[a]	63.20±0.50	62.74±0.17	-0.5±0.5	-66.1
(2) via CuF_2^+	874-1005	33[b]	65.82±0.72	64.992±0.33	-0.9±0.8	-63.8
(2) via CuF^+	874-1005	33[b]	65.92±0.67	65.085±0.30	-0.9±0.7	

(a) Two data points eliminated by a statistical test.

(b) One data point eliminated by a statistical test.

We adopt $\Delta_f H°(CuF_2, g, 298.15\ K) = -63.8 \pm 3$ kcal mol^{-1}.

Heat Capacity and Entropy

The bond distance is taken from Brewer et al. (3). The bond distances for all of the transition metal difluorides from chromium through copper were estimated to be the same with the assessment that an error of 0.5 Å would lead to an error of less than 1 cal K^{-1} mol^{-1} in the entropy. The bond angle and vibrational frequencies are those derived by Hastie et al. (4) from infrared studies of matrix-isolated isotopic species. The electronic states and levels are assumed the same as those assigned to $CuCl_2$ (5). The principal moments of inertia are $I_A = 0.1990 \times 10^{-39}$, $I_B = 18.3484 \times 10^{-39}$, $I_C = 18.5474 \times 10^{-39}$ g cm^2.

PREVIOUS: December 1977 (1 atm) CURRENT: December 1977 (1 bar)

COPPER HYDROXIDE ($Cu(OH)_2$) CRYSTAL M_r = 97.56068

$S°(298.15\ K)$ = [108.366] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K)$ = -450.37 ± 8.4 kJ mol^{-1}

Enthalpy of Formation

The enthalpy change, $\Delta_r H°(433\ K)$, for the reaction $Cu(OH)_2(cr) = CuO(cr) + H_2O(g)$ has been determined by My (1). Based on the reported value, $\Delta_r H°(433\ K)$ = 12 kcal mol^{-1}. The adopted $\Delta_f H°(Cu(OH)_2, cr, 298.15\ K)$ value was derived as -107.64 kcal mol^{-1}, using $\Delta_f H°(298.15\ K)$ = -37.250 and -57.798 kcal mol^{-1} for CuO(cr) and $H_2O(g)$, respectively.

The Gibbs energy change, $\Delta_r G°(298.15\ K)$, of the reaction $Cu(OH)_2(cr) = Cu^{++}(aq) + 2\ OH^-(aq)$ was evaluated to be 26.36 and 26.26 kcal mol^{-1}, based on the solubility product for $Cu(OH)_2(cr)$ reported by Ganelina (2) and Zhuk (3), respectively. Using values of $S°(298.15\ K)$ and $\Delta_f H°(298.15\ K)$ for $Cu^{++}(aq)$ and $OH^-(aq)$ from (4) and (5), the corresponding enthalpy change $\Delta_r H°(298.15\ K)$ and enthalpy of formation, $\Delta_f H°(298.15\ K)$ for $Cu(OH)_2(cr)$ were derived. The results obtained are presented as follows:

Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}	Source
$Cu(OH)_2(cr) = Cu^{++}(aq) + 2\ OH^-(aq)$	10.06	-104.61	(1)
$Cu(OH)_2(cr) = Cu^{++}(aq) + 2\ OH^-(aq)$	9.97	-104.52	(2)
$CuO(cr) + H_2O(\ell) = Cu(OH)_2(cr)$	-1.9	-107.5	(3)
$CuO(cr) + H_2O(\ell) = Cu(OH)_2(cr)$	0.3	-105.3	(4)

The enthalpies of solution of CuO(cr) and $Cu(OH)_2(cr)$ in $HNO_3(aq)$ have been determined by de Forcrand (6) to be -16.38 and -14.46 kcal mol^{-1}, respectively. From these data, the enthalpy change for the reaction $CuO(cr) + H_2O(\ell) = Cu(OH)_2(cr)$ was derived as -1.9 kcal mol^{-1}. For the same reaction, the enthalpy change was reported to be 0.3 kcal mol^{-1} by Sabatier (7). Based on $\Delta_f H°(298.15\ K)$ = -37.25 and -68.315 kcal mol^{-1} for CuO(cr) and $H_2O(\ell)$, respectively, the enthalpy of formation for $Cu(OH)_2$ was evaluated. The results obtained are presented in the above table.

Heat Capacity and Entropy

The heat capacities, 298.15-700 K, were estimated by comparison with those for CuO(cr), CaO(cr) and $Ca(OH)_2(cr)$. The $C_p°$ values above 700 K were obtained by graphical extrapolation. $S°(298.15\ K)$ was estimated such that the derived $\Delta_f G°(Cu(OH)_2, cr) = \Delta_f G°(CuO, cr) + \Delta_f G°(H_2O, g)$ at 433 K.

Decomposition Data

T_{dcm} = 433 K is the temperature at which the Gibbs energy change for the reaction $Cu(OH)_2(cr) = CuO(cr) + H_2O(g)$ is such that the fugacity of water is 1 atm.

$S°(298.15\ K) = 42.59 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -153.81 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -156.06 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of CuO(cr) has been investigated calorimetrically (both oxidation and reduction reactions) and by extensive study of the $Cu_2O(cr) + 1/2\ O_2(g) = 2\ CuO(cr)$ equilibrium by pressure and by emf measurement. The more consistent data leading to the adopted value are summarized below.

*Reactions: (A) $Cu(cr) + H_2O(\ell) = CuO(cr) + H_2(g)$
(B) $Cu(cr) + 1/2\ O_2(g) = CuO(cr)$
(C) $Cu_2O(cr) + 1/2\ O_2(g) = 2\ CuO(cr)$

**Based on third law where possible and $\Delta_f H°(Cu_2O, cr, 298.15\ K) = -40.8$ kcal mol^{-1} in Reaction C.

Thomsen's data (1) may be reduced to the enthalpy of reduction of CuO(cr) with H_2 by combining enthalpies of reaction for CuO + H_2SO_4, Fe + H_2SO_4, and Fe + $CuSO_4$(aq). Wartenberg and Werth (2) and Nunez et al. (4) have measured the direct enthalpy of reduction of CuO(cr) by H_2; Mah et al. (3) and Nunez et al. (4) have measured the direct enthalpy of oxidation of copper by O_2. Mah et al. (3) obtained a mixed Cu_2O and CuO product and used $\Delta_r H°(298.15\ K) = -33.63 \pm 0.05$ kcal mol^{-1} for the equilibrium reaction $Cu_2O(cr) + 1/2\ O_2(g) = 2\ CuO(cr)$ to resolve their results into $\Delta_f H°(CuO, cr, 298.15\ K)$ and $\Delta_f H°(Cu_2O, cr, 298.15\ K)$. From the measurment of the reduction of coarse and fine CuO(cr), Nunez et al. (4) conclude that $\Delta_f H°$ of the copper oxides is influenced by material history, state of subdivision, and non-stoichiometry.

Eliminating three studies (5, 17, and 18) from our 3rd law analysis because of large drift and poor 2nd and 3rd law agreement, the average of the eleven remaining studies is -37.32 kcal mol^{-1}. We adopt $\Delta_f H°(298.15\ K) = -37.3 \pm 0.5$ kcal mol^{-1}.

Heat Capacity and Entropy

The adopted values are based on the low temperature heat capacities by Hu and Johnston (19, 15-297 K) and the high temperature enthalpies by Mah et al. (3, 410-1400 K). Changes are made where appropriate to adjust to the 1975 atomic weights (20) and the IPTS-68 temperature scale (21). A small anomaly in the heat capacity is observed in the 210-230 K region. Magnetic measurements of O'Keefe and Stone (22) and neutron diffraction studies of Brockhouse (23) suggest that this is a Neel point associated with antiferromagnetism.

The entropy is obtained from the adopted heat capacities based on a T^3 extrapolation to obtain $S°(15\ K) = 0.016$ kcal mol^{-1}.

Decomposition Data

T_{dcm} = 1397 K is the temperature at which fugacity (O_2) = 1 atm for the reaction $2\ CuO(cr) = Cu_2O(cr) + 1/2\ O_2(g)$.

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = 73.2 \pm 10\ kcal\ mol^{-1}$ comes from our 3rd law analysis of the mass-spectrometric Knudsen cell measurements of the equilibrium reaction CuO(g) + Ni(g) = Cu(g) + NiO(g) (1611 - 1828 K) (1). Auxiliary data (2, 3) are used in the analysis. Also considered in the evaluation are: the unpublished but quoted (4, and others] value of Burns, $D_0^0 = 62.7 \pm 3$ *kcal mol*$^{-1}$, the *sublimation measurement* of (5), the linear Birge-Sponer extrapolation of the ground state to obtain D_0^0, and the linear Birge-Sponer extrapolation corrected for the ionic character of CuO according to (6).

Source	$D°(0\ K)$	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Smoes et al. (1), Equilibrium	66.3	73.2
Burns (4), Mass spec.	62.7±3	76.8±3
Mack et al. (5), *Transpiration (1273 K)*	80.2	59.02
Linear Birge-Sponer	65.2	74.2
Modified Linear Birge-Sponer	61.0±12	78.5±12

Mack et al. (5) report measurements at 873, 1073, and 1173 K which lead to higher dissociation energies. Because of the scatter of the measurements and the suspect nature of the analytical measurement recognized by the authors, the D_0^0 value of 80.2 kcal mol^{-1} is discounted.

Heat Capacity and Entropy

The molecular constants and electronic levels are taken from the work of Appelblad and Lagerqvist (7, 8, 9), Lefebvre et al., (10) and Lefebvre et al. (11). *The spectrum of CuO is complex and there are almost certainly excited states missing among those* already analyzed (9); in fact some doubt still exists that the $X^2\Pi_i$ state is really the ground state (9) although the absence of esr signals in the matrix isolation study of Thompson et al. (12) supports this assignment. Because of the uncertain and incomplete spectral analysis, we choose to calculate the thermodynamic functions with first-order anharmonic corrections assuming the ground-state vibrational-rotational constants for all states. Use of the actual constants for each state increases the entropy at 6000 K by 0.045 cal K^{-1} mol^{-1}.

PREVIOUS: December 1977 (1 atm) CURRENT: December 1977 (1 bar)

$S°(298.15\ K) = 109.254 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -760.059 \pm 0.84\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -769.982 \pm 0.84\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of solution, $\Delta_r H°(298.15\ K)$, of CuO(cr) in sulfuric acid to form $CuSO_4$(cr) has been measured by Adami and King (1). From the reported value, $\Delta_r H° = 5.61 \pm 0.09$ kcal mol^{-1} for the reacton CuO(cr) + $H_2SO_4 \cdot 7.068\ H_2O$(aq) = $CuSO_4$(cr) + 8.068 H_2O(ℓ), the enthalpy of formation, $\Delta_f H°(298.15\ K)$, for $CuSO_4$(cr) was evaluated as -184.03 kcal mol^{-1}, using $\Delta_f H°(298.15\ K)$ = -37.25, -209.49 and -68.315 kcal mol^{-1} for CuO(cr), $H_2SO_4 \cdot 7.068\ H_2O$(aq) and H_2O(ℓ), respectively. See $Fe_2(SO_4)_3$(cr) table for the sources of the last two $\Delta_f H°(298.15\ K)$ values.

The equilibrium pressure for the following chemical reactons: (A) 2 $CuSO_4$(cr) = $CuO \cdot CuSO_4$(cr) + SO_3(g), (B) 3 Cu(cr) + $CuSO_4$(cr) = 2 Cu_2O(cr) + SO_2(g), and (C) 4 $CuSO_4$(cr) + Cu_2O(cr) = 3 $CuO \cdot CuSO_4$(cr) + SO_2(g), were determined by several investigators. For reaction (A), the partial pressures of SO_3(g) at different temperatures were calculated from the measured total pressures exerted by SO_3(g), SO_2(g) and O_2(g) produced by the reaction $SO_3(g) = SO_2(g) + 1/2\ O_2(g)$. From these vapor pressure data, the corresponding enthalpy changes, $\Delta_r H°(298.15\ K)$, for the three reactions were evaluated by the 2nd and 3rd law methods. The results obtained are presented in the following table. The value of $\Delta_f H°(CuSO_4, cr, 298.15\ K)$ adopted was -184.03 ± 0.2 kcal mol^{-1}.

Source	Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

(5)	(B)	525.1 - 608.1	31.71±0.76	32.27	0.84±1.30	-184.62

Heat Capacity and Entropy

The low temperature heat capacities, 52.67-296.29 K were obtained from Weller (6). The high temperature heat capacities were measured by Schottky (7, 282°C), Ewald (8, 275-373 K), Krestovnikov and Feigina (9, 288-873 K), and Chiznikov and Khirik (10, 373-1273 K). The heat capacities below 51 K were obtained from Stout (11). In that paper, the $C_p°$ values, 15-58 K, were plotted as function of temperature and the $C_p°$ curve shows a maximum at 34.8 K. In an attempt to evaluate the entropy due to the anomalous portion of the curve, a "normal" heat capacity curve was drawn. The entropy above the normal $C_p°$ curve is reported to be 0.48 cal K^{-1} mol^{-1} rather than a magnetic entropy of Rln2 = 1.377 cal K^{-1} mol^{-1}. Apparently the magnetic entropy increases gradually above 40 K so that it is not feasible to separate the heat capacity due to magnetic effects from that of the crystal lattice.

The $C_p°$ values above 298.15 K were extrapolated smoothly by comparison with those for $MnSO_4$(cr) (see $FeSO_4$(cr) table for details). The adopted $C_p°$ values are close to the average of the reported $C_p°$ values.

The value of S°(298.15 K) was derived using the low temperature $C_p°$ data reported by Weller (6), based on S°(51 K) = 2.851 cal K^{-1} mol^{-1} evaluated from $C_p°$ data determined by Stout (11).

Decomposition Data

T_{dcm} = 1078 K is the temperature at which the total pressure of the gaseous decomposition products equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for $CuSO_4$(cr), determined by Ingraham (4).

$\omega_e = 265.34\ cm^{-1}$ $\omega_e x_e = 1.015\ cm^{-1}$ $\sigma = 2$
$B_e = 0.10776\ cm^{-1}$ $\alpha_e = 0.000608\ cm^{-1}$ $r_e = 2.219$ Å

Enthalpy of Formation

The enthalpy of formation is calculated from that of Cu(g) using $\Delta_r H°(298.15\ K) = 46.0\ kcal\ mol^{-1}$ for $Cu_2(g) \rightarrow 2\ Cu(g)$ obtained by 3rd law analysis of the mass spectrometric data of Ackerman et al. (1). Earlier studies of mass spectra and of the electronic band spectra yield values in reasonable agreement as shown below. The selected $\Delta_r H°$ corresponds to $D°(0\ K) = 1.97$ eV compared with the linear Birge-Sponer extrapolation of 2.1 eV.

Heat Capacity and Entropy

Molecular constants, except for $\omega_e x_e$, were taken from the rotational analysis of bands of the B-X system given by Travis and Barrow (5). The value for $\omega_e x_e$ was obtained from the earlier study of Kleman and Lindkvist (4) who showed by means of the vibrational isotope effect that the emitter was Cu_2. The spectroscopic characters of the ground and excited states are uncertain, but Travis and Barrow indicate that the transition is probably $^1\Sigma_u^+ - {}^1\Sigma_g^+$ for the B-X system. Vibrational and rotational constants were adjusted for 30.91% ^{65}Cu.

$S°(298.15\ K) = 92.36 \pm 0.34\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1516.7\ K$

$\Delta_f H°(0\ K) = -168.95 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -170.71 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 64.768 \pm 0.63\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Cu_2O(cr) has been investigated calorimetrically (both oxidation and reduction reactions) and the oxidation reaction 2 Cu(cr) + 1/2 O_2(g) = Cu_2O(cr) has been studied extensively by pressure and by emf measurement. The more consistent data leading to the adopted value are summarized below.

Source	Method	Reaction*	T/K	Points	$\Delta_r H°$(298.15 K), kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_r H°$(298.15 K) kcal mol^{-1}

*Reactions: (A) 2 Cu(cr) + H_2O(l) = Co_2O(cr) + H_2(g) (B) 2 Cu(cr) + 0.5 O_2(g) = Cu_2O(cr)

Thomsen (1) obtained $\Delta_f H°(298.15\ K)$ values of -40180, -40.87, and -41.51 kcal mol^{-1} from aqueous calorimetry using three different paths. He favored the first path which is recalculated by combination of the heats of reaction of $Cu_2O + H_2SO_4$, Fe + H_2SO_4, and Fe + $CuSO_4$(aq) to yield the heat of reduction of Cu_2O with H_2. Nunez et al (3) measured the direct heat of reduction of Cu_2O by H_2; the conclude that the heats of formation of the copper oxides are influenced by material history, state of subdivision, and non-stoichiometry. Mah et al. (2) measured the direct heat of oxidation of copper by O_2, but they obtained a mixed product of Cu_2O and CuO and used $\Delta_r H°(298.15\ K) = -33.63 \pm 0.05$ kcal mol^{-1} for the equilibrium reaction Cu_2O(cr) + 1/2 O_2(g) = 2 CuO(cr) to resolve their results into $\Delta_f H°(Cu_2O$, cr, 298.15 K) and $\Delta_f H°$(CuO, cr, 298.15 K). The overall average from our 3rd law analyses is -40.82 kcal mol^{-1}; without the outlier (10, 18, 19) the average is 40.81; the average of the six data sets with an absolute drift less than 1 is -40.77. We adopt $\Delta_f H°(Cu_2O$, cr, 298.15 K) = -40.8 ± 0.5 kcal mol^{-1}.

Heat Capacity and Entropy

The heat capacities are smoothed values adopted from a consideration of the work of Gregor (22, 2.8-21 K), Hu and Johnston (23, 15-300 K) and Mah et al. (2, 52-296 K, 406-1464 K). The data of Mah et al. (2) are favored over that of Hu and Johnston (23) above 120 K. Adjustment is made to the IPTS-68 temperature scale (24).

The entropy is based on a T^3 extrapolation to obtain $S°(2.8\ K) = 0.0015$ cal K^{-1} mol^{-1}.

Fusion Data

See the liquid table for details.

COPPER OXIDE (Cu_2O) LIQUID M_r = 143.0914

$S°(298.15\ K)$ = [129.957] J K^{-1} mol^{-1}

T_{fus} = 1516.7 K

$\Delta_f H°(298.15\ K)$ = [-111.995] kJ mol^{-1}

$\Delta_{fus} H°$ = 64.768 ± 0.63 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Cu_2O, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1516.7\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is taken from the enthalpy measurements of Mah et al. (1, 1521-1600 K) and is assumed constant at 23.88 cal K^{-1} mol^{-1} from 1000 to 2000 K. A glass transition is assumed at 1000 K below which the heat capacity is that of the crystal.

The entropy is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The melting point, 1515 K, was determined by drop calorimetry by Mah et al. (1). Correcting to the IPTS-68 temperature scale (2), we adopt T_{fus} = 1516.7 K.

$\Delta_{fus} H°$ = 15.48 ± 0.15 kcal mol^{-1} is based on our smoothing through the pre-melt region of the enthalpy measurements of Mah et al. (1).

PREVIOUS: CURRENT: December 1977

$S°(298.15\ K) = [157.318 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -927.593 \pm 1.3\ kJ\ mol^{-1}$

Enthalpy of Formation

The equilibrium pressures for the following reactions: (A) $CuO \cdot CuSO_4(cr) = 2\ CuO(cr) + SO_3(g)$ and $SO_3(g) = SO_2(g) + 0.5\ O_2(g)$ and (B) $CuO \cdot CuSO_4(cr) + Cu_2O(cr) = 4\ CuO(cr) + SO_2(g)$, were determined by Reinders (1) and Ingraham (2). Using the reported vapor pressures, the corresponding enthalpy changes were evaluated by both the 2nd and 3rd law methods. The results obtained are presented as follows:

Reference	Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	A*	1013-1093	53.03±2.53	52.43	-0.7±2.4	-221.5
(1)	B	917-1027	41.72±1.42	42.43	0.5±1.4	-221.7
(2)	A*	969-1138	50.92±0.16	52.57	1.5±0.2	-221.7

*Partial pressures were calculated from JANAF values for the $SO_3 - SO_2$ equilibrium.

The value of $\Delta_f H°(CuO \cdot CuSO_4, cr, 298.15\ K)$ adopted is -221.7 ± 0.3 kcal mol^{-1}.

Heat Capacity and Entropy

The heat capacities are calculated as the sum of those for CuO(cr) and $CuSO_4$(cr). The value of S°(298.15 K) is estimated by comparison with those for CuO(cr) and $CuSO_4$(cr) and adjusted so that, using the derived free energy functions, the 2nd and 3rd law values for $\Delta_r H°(298.15\ K)$ agree reasonably.

Decomposition Data

T_{dcm} = 1138 K is the temperature at which the total pressure of the gaseous decomposition products of reaction (A) equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for $CuO \cdot CuSO_4$(cr), determined by Ingraham (2).

Electronic Level and Quantum Weight

State	ε_1, cm^{-1}	g_1
$^2S_{1/2}$	0.00	2

Enthalpy of Formation

The adopted value for $\Delta_f H°(D, g, 298.15\ K)$ is derived using $D_0^0 = 36748.9 \pm 0.4\ cm^{-1}$ from Herzberg (1) and auxiliary data for D_2(2).

An earlier value for the dissociation energy was reported by Herzberg and Monfils (3) as $D_0^0 = 36743.6 \pm 0.5\ cm^{-1}$. Two theoretical studies by Kolos and Wolniewicz (4) and Bunker (5) yielded a vlue of $36748.2\ cm^{-1}$. More recently, LeRoy and Barwell (6), using a relationship involving the near-dissociation behavior of the rotational constants and the long range intermolecular potential, calculated $D_0^0 = 36748.88(\pm 0.3)\ cm^{-1}$.

Heat Capacity and Entropy

The electronic levels for D(g) are given in the compilation by Moore (7). Our calculations indicate that the inclusion of levels up to n = 12 has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of these levels; the first excited state lies at 82281 cm^{-1} above the ground state. Since the inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the gram formula weight and the fundamental constants. The gram formula weight is that recommended by IUPAC (8). Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cut off procedures (9).

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

DEUTERIUM, ION (D^+) IDEAL GAS M_r = 2.01355

$S°(298.15\ K) = 117.583 \pm 0.02\ JK^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1532.21 \pm 0.04\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [1540.324]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(D^+, g, 0\ K)$ is calculated from $\Delta_f H°(D, g, 0\ K)$ (1) using the spectroscopic value of IP(D) = 109708.608 ± 0.005 cm^{-1} (313.6727 ± 0.0001 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(D^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(D, g, 0\ K)$ by using IP(D) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for D(g), $D^+(g)$, and $e^-(g)$. $\Delta_f H°(D \rightarrow D^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by −6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The thermodynamic functions of the proton gas are calculated using the recent CODAT fundamental constants (2) and assuming that the proton is an ideal monatomic gas. Since there is no electron associated with this species, there is only a translational contribution to the thermochemical function.

Enthalpy of Formation

$\Delta_f H°(D^-, g, 0\ K)$ is calculated from $\Delta_f H°(D, g, 0\ K)$ (1) using the adopted electron affinity of EA(D) = 0.754209 ± 0.000003 eV (72.7696 ± 0.0003 kJ mol^{-1}). This value is assumed to be the same as that recommended by Hotop and Lineberger (2) for H(g). Additional information on $D^-(g)$ and $H^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 3), Rosenstock et al. (4) and Massey (5).

$\Delta_f H°(D^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(D, g, 0\ K)$ by using EA(D) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $D^-(g)$, D(g), and $e^-(g)$. $\Delta_r H°(D^- \rightarrow D + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $D^-(g)$ is given by Hotop and Lineberger (2, 3) and Rosenstock et al. (4).

A comparison of the isoelectronic sequence - $H^-(g)$, He(g), and $Li^+(g)$ - would suggest that stable electronic states may exist at 0.8 EA(H) or roughly 6400 cm^{-1}. This would greatly affect the entropy. However, Pekeris (6) states that he was unable to find any bound states. In addition, Seman and Branscom (7) state that theoretical and semiempirical evidence suggests that atomic negative ions have very few if any excited states below the continuum. We assume that the same arguments apply for $D^-(g)$ and that no stable excited states exist.

Enthalpy of Formation

The enthalpy of formation was calculated from $\Delta_f H°(298.15\ K)$ of HF(g), -65.13±0.2 kcal mol^{-1}, given in JANAF Thermochemical Tables (1) the appropriate thermal functions (see tables for H_2, D_2, DF and HF (1), and the estimated zero point energies. The energies for H_2(g) and D_2(g) are those given by Herzberg and Monfils (2). The energies for HF(g) and DF(g) include the Dunham correction and were calculated from the data given by Mann et al. (3) and Spanbauer et al. (4).

Heat Capacity and Entropy

The vibrational and rotational constants of the respective electronic levels were taken from Rosen (5). The National Bureau of Standards prepared this table (6) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (6), we recalculate the table in terms of 1973 fundamental constants (7), 1975 atomic weights (8), and current JANAF reference states for the elements.

$\Delta_f H°(0\ K) = 0.330 \pm 0.008\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0.321 \pm 0.013\ kJ\ mol^{-1}$

Vibrational and Rotational Levels (cm^{-1})

Direction Summmation of Electronic Ground State:

$$E = G - G_o + F = G - G_o + BZ - DZ^2 + HZ^3 - LZ^4 + \ldots \simeq G - G_o + BZ - DZ^2 + H^2Z^3/(H+LZ),$$

where $Z = J(J+1)$, $Y = v+1/2$, and we omit subscript v on G, F, B, D, H, and L

$$G = 3815.403Y - 93.61504Y^2 + 1.39630Y^3 - 0.118666Y^4 + 5.97675 \times 10^{-3}Y^5 - 2.08092 \times 10^{-4}Y^6$$

$$B = 45.66910 - 2.031845Y + 7.27360 \times 10^{-2}Y^2 - 1.82824 \times 10^{-2}Y^3 + 3.06318 \times 10^{-3}Y^4 - 3.00453 \times 10^{-4}Y^5 + 1.47623 \times 10^{-5}Y^6 - 2.9887 \times 10^{-7}Y^7$$

$$D = 2.6527 \times 10^{-2} - 1.1534 \times 10^{-3}Y + 1.7075 \times 10^{-4}Y^2 - 2.1142 \times 10^{-5}Y^3 + 9.9570 \times 10^{-7}Y^4$$

$$H = 2.206 \times 10^{-5} - 2.648 \times 10^{-6}Y + 3.047 \times 10^{-7}Y^2 - 1.327 \times 10^{-8}Y^3$$

$$L = 2.122 \times 10^{-8} - 3.912 \times 10^{-9}Y + 3.298 \times 10^{-10}Y^2$$

$$v_{max} = 17, \qquad J_{max} = 46 - 42\ v/v_{max}$$

Ground State Configuration: $^1\Sigma^+$ Symmetry Number = 1

Enthalpy of Formation

$\Delta_f H°(0\ K)$ is derived from D_0^0 = 36406.0±0.4 cm^{-1} (104.090±0.001 kcal mol^{-1}) based on absorption limits analyzed by Herzberg (1). He derived D_0^0 values of 36406.6 and 36405.8 cm^{-1} from lower and upper absorption edges. Thorson (2), by theoretical treatment of absorption-edge doubling, concluded that the value from the upper edge is more accurate. *We adopt a value closer to* that from the upper edge and essentially the same as that selected by the National Bureau of Standards (3).

Heat Capacity and Entropy

These are calculated by direct summation (4) over vibrational-rotational energy levels of the electronic ground state. We performed the direct summation with an extended version of a program written by W. H. Evans and provided through cooperation of D. D. Wagman, both of the U. S. National Bureau of Standards. Contributions of excited states (T_0 > 9000 cm^{-1}, 5) are negligible at 6000 K.

Vibrational-rotational levels are represented by the polynomials given above. G, B, and D are our fits of data from Dabrowski and Herzberg (5). Data from Durie and Herzberg (6), McKellar et al. (7), Brannon et al. (8) and Stoicheff (9) were also used where appropriate. Observed HD data extend to v_{max} = 17 for G and B, v = 16 for D, but only v = 1 for H. We estimate polynomials H and L by isotopic relations from those of H_2 (4) in order to provide a similar extrapolation to high J values. Our H polynomial differs from H_0 and H_1 (8, 9) by less than the experimental uncertainty. Our combination of H and L should be consistent with our adopted approximation for the infinite series (F) of rotational levels. We assume that F has the form proposed by Khachkuruzov (10) and Woolley et al. (11). We assume a linear approximation (10) for the limiting values (J_{max}) of rotational quantum number. Values in the J_{max} equation are estimated by comparison with H_2 and D_2 (4) so that J_{max} is consistent with observation for HD (5) of a rovibrational level at J = 6, v = 16.

Thermodynamic functions are calculated using 1973 fundamental constants (12), 1975 atomic weight of H, and 1973 isotopic mass of D (13). Results apply either to $^1H^2H$ or to HD containing H of natural abundance, even though the vibrational-rotational constants are for $^1H^2H$. Maximum difference between thermodynamic functions for $^1H^2H$ and HD is 0.0002 cal K^{-1} mol^{-1} in S°(298.15 K). Our calculations agree to within 0.002 cal K^{-1} mol^{-1} (or kcal mol^{-1}) with those of Woolley et al. (11) up to 2000 K. The more approximate C_p^o values of NBS (3) differ by less than 0.04 cal K^{-1} mol^{-1} in the range 3000 to 6000 K. We omit the nuclear-spin contribution (R ln 6) to entropy and Gibbs-energy function.

Direct Summation using Energy-Level Equations for the $^2\Sigma_g^+$ Electronic Ground State:

$E = G - G_o + F = G - G_o + BZ - DZ^2 + HZ^3 - LZ^4 + \ldots \approx G - G_o + BZ - DZ^2 + H^2Z^3/(H+LZ)$

where $Z = N(N+1)$, $Y = v+1/2$, and we omit subscript v on G, F, B, D, H, and L

$G = 2012.19\ Y - 50.5532\ Y^2 + 0.0604244\ Y^3 - 0.0163194\ Y^4$

$B = 22.4643 - 1.03566\ Y + 0.0180076\ Y^2 - 0.000633616\ Y^3$ $r_e = 1.057$ Å

$D = 1.12041\times10^{-2} - 4.24035\times10^{-4}\ Y + 1.26643\times10^{-5}\ Y^2$

$H = 7.26086\times10^{-6} - 2.19375\times10^{-7}\ Y$ and $L = 5.06679\times10^{-9}$

$v_{max} = 21$ and $N_{max} = 47 - 38v/v_{max}$

Electronic statistical weight = 2 and rotational statistical weights = 1(even and odd N)

Enthalpy of Formation

$\Delta_f H°(0\ K) = 356.238\pm0.005$ kcal mol^{-1} is obtained from that of HD(g) (1) using IP(HD) = 124568.5±1.2 cm^{-1}(356.159±0.004 kcal mol^{-1}). Takezawa and Tanaka (2) determined IP = 124569.5±0.6 cm^{-1} from Rydberg spectra of HD. Similar studies on H_2 by Herzberg and Jungen (3) revealed a bias of ~1.0 cm^{-1} attributed to a pressure shift in the spectra. We assume an equal shift for HD, adjust IP by -1.0 cm^{-1} and increase the uncertainty due to this adjustment. $\Delta_f H°(0\ K)$ is converted to $\Delta_f H°(298.15\ K)$ by use of JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for H_2, D_2, HD^+ and e^-(g). The difference in $\Delta_f H°(298.15\ K)$ between HD^+ and HD should not be interpreted as a room-temperature ionization threshold due to inclusion of these enthalpies and to threshold effects noted by Rosenstock et al. (4).

The adopted spectroscopic IP(HD) receives strong support from a value calculated indirectly from experimental values (1) of $D_0^0(HD)$ and IP(H) combined with the theoretical value (5) of $D_0^0(HD^+)$; this indirect value differs by only 0.3 cm^{-1}. Furthermore, IP(HD) can be predicted (6) approximately from that of H_2 (or D_2) using differences in zero-point energies (1) of the diatomic molecules and their ions. Predicted values of IP(HD) deviate from the observed value by -16 cm^{-1} (based on H_2) and +16 cm^{-1}(based on D_2). Inclusion of an empirical adjustment for the difference IP(D) - IP(H) overcorrects the predictions, giving deviations of +14 cm^{-1} (based on H_2) and -14 cm^{-1} (based on D_2). The average of deviations derived from H_2 and D_2 is zero, suggesting that the slight discrepancies are due to the approximate nature of the prediction. An approximate photoionization result, reviewed by Rosenstock et al. (4), deviates from the spectroscopic result by ~130 cm^{-1}.

Heat Capacity and Entropy

Thermodynamic functions for ortho-para "equilibrium" HD^+ are calculated by direct summation using the energy-level equations listed above. We use 1973 fundamental constants (7) in an extended version of a computer program written by W. H. Evans and provided by D. D. Wagman of the U. S. National Bureau of Standards. Excited electronic states are neglected because they do not contribute significantly. The electronic statistical weight is taken equal to the multiplicity since we neglect the very small rotational splitting (8).

Coefficients of the energy-level polynomials are calculated from the theoretical values of H_2^+(1) using rho = 0.866117 in isotopic equations. These polynomials are confirmed by six rotation-vibration transitions ($v\leq3$, $N\leq2$) observed between 1642 and 1869 cm^{-1} by an infrared laser-resonance method (8). Our polynomials predict these transitions within 0.1 cm^{-1}. We give the polynomial coefficients, especially higher order ones, to many more digits than are justified by their accuracy. The equations are very approximate near N_{max} but, judging by H_2^+ (1), this should have little effect on the thermodynamic functions even at 6000 K. The approximate v_{max} is derived from the G polynomial.

The thermodynamic functions include contributions from quasi-bound levels lying above $D_0^0(HD^+ \rightarrow H^+ + D)$ = 21516 cm^{-1}. At 6000 K these levels contribute 0.39 cal $K^{-1}\ mol^{-1}$ to $C_p°$ and 0.048 cal $K^{-1}\ mol^{-1}$ to the Gibbs-energy function. Their contribution is negligible below 3000 K. Limiting rotational quantum numbers N_{max} are estimated from H_2^+, H_2 and HD (1) by comparing energy increments and rotational quanta found above the respective values of D°. The crudity of these estimates makes $C_p°$ at 6000 K somewhat more uncertain than in the case of H_2^+ (1).

Enthalpy of Formation

The enthalpy of formation at 0 K for $HD^-(g)$ is based on the electron affinity value from a Rydberg-Klein-Rees configuration-interaction calculation for H_2^- (1). This study by Sharpe (1) led to $EA(H_2) = -2.5$ eV. Assuming this value is valid for $HD^-(g)$ and using auxiliary data (2), we calculate $\Delta_f H°(0\ K) = 57.73 \pm 10$ kcal mol^{-1} and $D°(HD^-) = 29.0 \pm 10$ kcal mol^{-1}; the latter value is calculated for dissociation into ground state D(g) and $H^-(g)$ or $D^-(g)$ and H(g). The adopted EA (H_2) value is suggested to be the more reliable value of eight studies considered by Rosenstock et al. (3).

In terms of molecular orbitals, the ground state for $HD^-(g)$ is the $(1s\sigma_g)^2\ (2p\sigma_u)^2\ ^2\Sigma_u^+$ state involving two bonding electrons and one antibonding electron. We would expect, however, the ground state to be $(1s\sigma_g)^2(1s\sigma_u)$. As stated by Massey (4), we should expect only a weakly-bound molecule as compared with HD(g) for which the ground state has no electron in an antibonding orbital. Our adopted calculated EA (HD) value is consitent with this viewpoint. Further discussion of the $HD^-(g)$ ion may be found in Massey (4).

$\Delta_f H°(0\ K)$ is converted to $\Delta_f H°(298.15\ K)$ by use of JANAF (2) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $D_2(g)$, $H_2(g)$, $DH^-(g)$, and $e^-(g)$. $\Delta_f H°(298.15\ K)$ should not be interpreted as a room temperature electron affinity due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al (3).

Heat Capacity and Entropy

The vibrational constants for $H_2^-(g)$ are estimated to be the same as in the isoelectronic species He_2^+ (5). The vibrational constants for $HD^-(g)$ are calculated from those for $H_2^-(g)$ using isotopic relations. The internuclear distance is estimated to be ~8% larger than that for $He_2^+(g)$. The same relationship appeared to exist for the (N_2^-, NO, O_2^+) isoelectronic series. B_e is calculated from r_e whereas α_e is calculated assuming a Morse function for the ground state.

The ground and excited electronic states are discussed in detail by Massey (4). No excited state contributions are included in this calculation.

$S°(298.15\ K) = 199.512\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -242.435 \pm 0.063\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -245.371 \pm 0.063\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
2723.66(1)
1402.80(1)
3707.47(1)

Ground State Quantum Weight: 1 $\sigma = 1$

Point Group: C_h

Bond Distances: O-H = 0.9584 Å O-D = 0.9854 Å

Bond Angle: H-O-D = 104.45°

Product of the Moments of Inertia: $I_A I_B I_C = 1.59584 \times 10^{-119}\ g^3\ cm^6$

Enthalpy of Formation

3rd and 2nd law (where possible) analyses of the more recent determinations (1-5) of the experimental equilibrium constants, Keq, were made for the reacitons: (A) $H_2O(g) + HD(g) = HDO(g) + H_2(g)$, and (B) $H_2O(g) + D_2O(g)$. Spectroscopic values for the heats of reaction, $\Delta_r H°(298.15\ K)$, of (A) and (B) were based on the zero point energies of H_2O, D_2O, and HDO given by Hulston (6) and Wolfsberg (7) and H_2, HD given by Herzberg and Monfils (8). The earlier work on (A) cited by Kirshenbaum (9) is in poor agreement except for that of Herrick, Kirshenbaum, Brown and Herrick, Crist, Davis $\Delta_r H°(298.15\ K)$ = 928±30, 921 kcal mol^{-1}, respectively). $\Delta_r H°(298.15\ K)$ for the reaction (C) $H_2O(\ell) + D_2O(\ell) = 2\ HDO(\ell)$ has been determined to be -32±1 cal $K^{-1}\ mol^{-1}$ (10-12) assuming ideal solutions (see (13)) and Keq(C) ~3.8. (We calculate Keq(C) = 3.76±0.04 from Keq(B) = 3.76±0.02, $P°(H_2O)/P°(D_2O)$ = 1.151±0.006 (14) at 298.15 K, and $P°(H_2O)/P°(HDO)$ = 1.073±0.004 (15) at 298.15 K.) $\Delta_r H°(298.15\ K)$ of (B) was calculated from the difference in enthalpies of vaporization at 298.15 K of $D_2O(\ell) - H_2O(\ell)$ = 331±8 cal (see D_2O table), and $HDO(\ell) - H_2O(\ell)$ = 183±20 cal $K^{-1}\ mol^{-1}$ (14). Values selected for $\Delta_r H°(298.15\ K)$ based on non-spectroscopic and spectroscopic work for (A) and (B), underlined in the table, were used to calculate values of $\Delta_f H°(298.15\ K)$ of $HDO(g) - H_2O(g)$ of -845±6, -852±12, and -851±10 cal $K^{-1}\ mol^{-1}$, respectively (see D_2O and HD tables). An average value of -850±10 cal $K^{-1}\ mol^{-1}$ was added to $\Delta_f H°(298.15\ K)$ of $H_2O(g)$ to obtain $\Delta_f H°(HDO, g, 298.15\ K)$.

[a]Second law: $\Delta_r H°(298.15\ K)$, $S°(298.15\ K)$ (obsv.-calc.); [b]Keq at temperature cited.

Heat Capacity and Entropy

The thermodynamic functions of this table are analogous to those in the JANAF table for $H_2O(g)$ (March 31, 1961): both tables are tablen from Friedman and Haar (16). Friedman and Haar (16) applied their non-rigid-rotor, anharmonic-oscillator treatment (with vibrational-rotational coupling terms and low-temperature rotational corrections) to the infrared-spectra analyses of Benedict et al. (17, 18). In the present table for HDO, the values of $C_p°$ of Friedman and Haar (16) between 4000 and 5000 K were extrapolated linearly (except with a term in T^{-2}) from 5000 to 6000 K. $I_A = 0.1213 \times 10^{-39}$, $I_B = 0.3071 \times 10^{-39}$, $I_C = 0.4284 \times 10^{-39}$ gm cm^2 from Friedman and Haar (16). The National Bureau of Standards prepared this table (19) by critical analysis of data existing in 1972.

Symmetry Number = 1

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ of ND(g) minus NH(g) was calculated from the JANAF thermal functions and the zero point energies of $H_2(g)$, $D_2(g)$ [given by Herzberg and Monfils (1)], NH(g), and ND(g) [given by Haar, et al. (2)]. $\Delta_f H°(298.15\ K)$ of ND(g) was calculated from this value and the JANAF selection for $\Delta_f H°(298.15\ K)$ of NH(g) (3).

Heat Capacity and Entropy

The molecular constants which are given for NH in the JANAF Thermochemical Tables (3) were adjusted for the isotope effect. The National Bureau of Standards prepared this table (4) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (4), we recalculate the table in terms of 1973 fundamental constants (5), 1975 atomic weights (6), and current JANAF reference states for the elements.

Symmetry Number = 1

Enthalpy of Formation

The enthalpy of formation was calculated from the selected value for $\Delta_f H°(298.15\ K)$ of OH(g), -0.27±3 kcal mol^{-1} (8), the appropriate thermal functions, and zero point energies of $H_2(g)$, $D_2(g)$, OH(g), and OD(g). The zero point energies of $H_2(g)$ and $D_2(g)$ were taken from Herzberg and Monfils (1). The zero point energies of OH and OD include the Dunham correction (see Herzberg and Monfils (1)). The molecular constants are those given by Rosen (2) with the exception of the spin-coupling constants taken from Herzberg (3).

Heat Capacity and Entropy

The vibrational and rotational constants of the respective electronic levels were taken from Rosen (2). Comparison of the results with those from a more exact treatment given by Haar et al. (4) indicates errors in the table above 400 K are negligible. Below this, they may be appreciable. In particular, it is recommended that H°(0 K) - H°(298.15 K), S°(298.15 K) and $C_p°$(298.15 K) be taken as -2.151 kcal mol^{-1}, 45.307 cal K^{-1} mol^{-1}, and 7.156 cal K^{-1} mol^{-1}, respectively. These errors result from dealing with the ground state ($X^2\Pi_i$) as two different electronic states separated by 139.7 cm^{-1}.

The National Bureau of Standards prepared this table (5) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (5), we recalculate the table in terms of 1973 fundamental constants (6), 1975 atomic weights (7), and current JANAF reference states for the elements.

Enthalpy of Formation

The enthalpy of formation was calculated from the appropriate thermal functions (see tables for HS, DS, H_2, D_2, 1), the selected value for $\Delta_f H°(298.15\ K)$ of HS(g) (33.3±1.2 kcal mol^{-1}, see table for HS(g), 1), and the zero point energies of H_2(g) (2), D_2(g) (2), HS(g) (3), and DS(g) (3). The Dunham corrections were made in ref. (2) for H_2(g) and D_2(g). Spectroscopic constants tabulated in ref. (3) were used to calculate the zero point energies of HS and DS including Dunham corrections.

Heat Capacity and Entropy

The vibrational and rotational constants of the respective electronic levels were taken from Rosen (3). From a comparison of this approximate calculation with more exact methods (see HS(g) table, 1) it is concluded that the errors are negligible above 400 K. Below this, they may be appreciable. In particular, it is recommended that H°(0 K) - H°(298.15 K), S°(298.15 K) and $C_p°$(298.15 K) be taken as -2.171 kcal mol^{-1}, 48.138 cal K^{-1} mol^{-1}, and 7.760 cal K^{-1} mol^{-1}, respectively. These errors result from dealing with the ground state ($^2\Pi_i$) as two different electronic states separated by 376.8 cm^{-1}.

The National Bureau of Standards prepared this table (4) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (4), we recalculate the table in terms of 1973 fundamental constants (5), 1975 atomic weights (6), and current JANAF reference states for the elements. Our calculated $C_p°$ values agree with the NBS table up to 4000 K; above 4000 K our values trend slightly higher and at 6000 K the difference from the original NBS table is 0.017 cal K^{-1} mol^{-1}.

Direct Summation of Electronic Ground State

$$E = G - G_0 + F = G - G_0 + BZ - DZ^2 + HZ^3 - LZ^4 + \ldots \approx G - G_0 + BZ - DZ^2 + H^2Z^3/(H+LZ),$$

where $Z = J(J+1)$, $Y = v+1/2$, and we omit subscript v on G, F, B, D, H, and L

$$G = 3116.334Y - 62.50516Y^2 + 0.7797565Y^3 - 5.48262\times10^{-2}Y^4 + 2.25748\times10^{-3}Y^5 - 6.30154\times10^{-5}Y^6$$

$$B = 30.45273 - 1.102045Y + 0.0295505Y^2 - 5.99912\times10^{-3}Y^3 + 8.37740\times10^{-4}Y^4 - 6.87040\times10^{-5}Y^5 + 2.80134\times10^{-6}Y^6 - 4.68952\times10^{-8}Y^7$$

$$D = 0.011525 - 3.6876\times10^{-4}Y + 4.1199\times10^{-5}Y^2 - 4.4723\times10^{-6}Y^3 + 1.7858\times10^{-7}Y^4$$

$$H = 6.55\times10^{-6} - 6.42\times10^{-7}Y + 6.03\times10^{-8}Y^2 - 2.15\times10^{-9}Y^3$$

$$L = 4.20\times10^{-9} - 6.32\times10^{-10}Y + 4.35\times10^{-11}Y^2$$

$$v_{max} = 21,\ J_{max} = 54 - 47v/v_{max}$$

Normalized statistical weights = 2/3 (even J) and 1/3 (odd J)

Ground State Configuration: $^1\Sigma_g^+$ r_e = 0.7415 Å

Enthalpy of Formation

Zero by definition. Refer to the monatomic deuterium gas table for a discussion of the dissociation energy.

Heat Capacity and Entropy

These are calculated by direct summation (1) over vibration-rotation energy levels of the electronic ground state. We performed the direct summation with an extended version of a program written by W. H. Evans and provided through cooperation of D. D. Wagman, both of the U. S. National Bureau of Standards. Contributions of excited states (T_0 > 90000 cm^{-1}) are negligible at 6000 K. Polynomials G, B and D are our fits of data from Stoicheff (2) and Bredohl and Herzberg (3). Polynomials H and L are estimated by isotopic relations from those of H_2 (1) in order to provide a similar extrapolation to high J values. The adopted H polynomial is not more accurate than the relatively scattered data (2-4), but it should be more consistent with our adopted approximation for the infinite-series (F) equation for rotational levels. We assume that F has the form proposed by Khachkuruzov (5) and Woolley et al. (6). We use a linear approximation for the limiting values (J_{max}) of rotational quantum number. The J_{max} equation is estimated; its second value has been revised from 52 (in the 1977 table) to 47 in order to yield $C_p°$ and S° values that agree more closely with theory (8) near 6000 K. We omit the nuclear-spin contribution (R ln 9) to entropy and Gibbs energy function.

We adopt ortho-para "equilibrium" D_2 as the reference state at all temperatures. Values differ from "normal" D_2 only at 100 K (6, 7). Our values can be compared with the theoretical results of Kosloff et al. (8) and Gurvich et al. (9) and with the earlier table of NBS (7). Our S° values deviate by 0.001 (8) or -0.005 (9) cal K^{-1} mol^{-1} at 6000 K. Our $C_p°$ values deviate by 0.011 (8), -0.002 (9) or 0.002 (7) at 5000 K and by 0.001 (8) or -0.005 (9) cal K^{-1} mol^{-1} at 6000 K.

$\Delta_f H°(298.15\ K) = [1498.567]\ kJ\ mol^{-1}$

Vibrational and Rotational Levels (cm^{-1})

Direct Summation using Energy-Level Equations for the $^2\Sigma_g^+$ Electronic Ground State:

$$E = G - G_o + F = G - G_o + BZ - DZ^2 + HZ^3 - LZ^4 + \ldots = G - G_o + BZ - DZ^2 + H^2Z^3/(H+LZ),$$

where $Z = N(N+1)$, $Y = v+1/2$, and we omit subscript v on G, F, B, D, H, and L

$$G = 1643.29\ Y - 33.7163\ Y^2 + 0.329116\ Y^3 - 0.00725916\ Y^4$$

$$B = 14.9825 - 0.564098\ Y + 0.00801011\ Y^2 - 0.000230173\ Y^3 \qquad r_3 = 1.057\ Å$$

$$D = 4.98379\times10^{-3} - 1.54039\times10^{-4}\ Y + 3.75711\times10^{-6}\ Y^2$$

$$H = 2.15408\times10^{-6} - 5.31503\times10^{-8}\ Y \text{ and } L = 1.00253\times10^{-9}$$

$$v_{max} = 26 \text{ and } N_{max} = 57 - 46v/v_{max}$$

electronic statistical weight = 2 and normalized rotational statistical weights = 2/3 (even N) or 1/3 (odd N)

Enthalpy of Formation

$\Delta_f H°(0\ K) = 356.666 \pm 0.003$ kcal mol^{-1} is the ionization potential $IP(D_2) = 124745.6 \pm 1.2\ cm^{-1}$. *Takezawa and Tanaka* (1) determined $IP = 124746.6 \pm 0.6\ cm^{-1}$ from Rydberg spectra of D_2. Similar studies on H_2 by Herzberg and Jungen (2) revealed a bias of $-1.0\ cm^{-1}$ attributed to a pressure shift in the spectra. We assume an equal shift for D_2, adjust IP by $-1.0\ cm^{-1}$ and increase the uncertainty due to this adjustment. $\Delta_f H°(0\ K)$ is converted to $\Delta_f H°(298.15\ K)$ by use of JANAF (3) enthalpies $H°(0\ K) - H°(298.15\ K)$ for D_2, D_2^+ and e^-(g). $\Delta_f H°(298.15\ K)$ should not be interpreted as a room-temperature ionization threshold due to inclusion of these enthalpies and to threshold effects noted by Rosenstock et al. (4).

The adopted spectroscopic $IP(D_2)$ receives strong support from a value calculated indirectly from experimental values (3) of $D_0^0(D_2)$ and IP(D) combined with the theoretical value (5) of $D_0^0(D_2^+)$; this indirect value differs by only 0.4 cm^{-1}. Rosenstock et al. (4) review several less accurate determinations of $IP(D_2)$ and recommend a value calculated from $IP(H_2)$ using differences in zero-point energies of the diatomic molecules and their ions. Repeating this calculation with JANAF values (3), we predict an IP (D_2) which differs from the observed value by $-32\ cm^{-1}$. Inclusion of an empirical adjustment for IP(D) - IP(H) overcorrects the prediction, giving a deviation of $+28\ cm^{-1}$. These slight discrepancies are due (3, see HD^+, g) to the approximate nature of the prediction. Villarejo's average photoionization result (6), $IP(D_2) = 124757 \pm 180\ cm^{-1}$, deviates by $+11\ cm^{-1}$ from the spectroscopic value.

Heat Capacity and Entropy

Thermodynamic functions for ortho-para "equilibrium" D_2^+ are calculated by direct summation using the energy-level equations listed above. We use 1973 fundamental constants (7) in an extended version of a computer program written by W. H. Evans and provided by D. D. Wagman of the U. S. National Bureau of Standards. Excited electronic states are neglected because they do not contribute significantly. The electronic statistical weight is taken equal to the multiplicity since we neglect rotational splitting which should be very small (see HD^+ and H_2^+, 3).

Coefficients of the energy-level polynomials are calculated from the theoretical values of H_2^+ (3) using rho = 0.707330 in isotopic equations. Theoretical calculations (5) on D_2^+ provide confirmation of B_e, ω_e and $\omega_e x_e$; the latter two are confirmed by vibrational structure observed (6) in the photoionization threshold of D_2^+. We give the polynomial coefficients, especially higher order ones, to many more digits than are justified by their accuracy. The equations are very approximate near N_{max} but, judging by H_2^+ (3), this should have little effect on the thermodynamic functions even at 6000 K. The approximate v_{max} is derived from the G polynomial.

The thermodynamic functions include contributions from quasi-bound levels lying above $D_0^0 = 21712\ cm^{-1}$. At 6000 K these levels contribute 0.33 cal K^{-1} mol^{-1} to Cp° and 0.041 cal K^{-1} mol^{-1} to the Gibbs-energy function. Their contribution is negligible below 3000 K. Limiting rotational quantum numbers N_{max} are estimated from H_2^+, H_2 and D_2 (3) by comparing energy increments and rotational quanta found above the respective values of D_0^0. The crudity of these estimates makes Cp° at 6000 K somewhat more uncertain than in the case of H_2^+ (3).

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

$S°(298.15\ K) = 158.26 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [241.4 \pm 42]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [235.365]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$X^2\Sigma_u^+$	0	2

$\omega_e = [1202]\ cm^{-1}$ $\omega_e x_e = [17.5]\ cm^{-1}$ $\sigma = 2$
$B_e = [12.7]\ cm^{-1}$ $\alpha_e = [0.141]\ cm^{-1}$ $r_e = [1.15]$ Å

Enthalpy of Formation

The enthalpy of formation at 0 K for $D_2^-(g)$ is based on the electron affinity (EA) value derived from a Rydberg-Klein-Rees configuration interaction calculation for H_2^-(1). This study by Sharpe (1) led to $EA(H_2) = -2.5$ eV. Assuming the same value for D_2 and using auxiliary data (2), we calculate $\Delta_f H°(0\ K) = 57.7 \pm 10$ kcal mol^{-1} and $D_0^0(D_2^-) = 30.0 \pm 10$ kcal mol^{-1}, the latter value assumes dissociation into ground state D(g) and $D^-(g)$. The adopted $EA(H_2)$ value is suggested to be the more reliable value of eight studies considered by Rosenstock et al. (3).

In terms of molecular orbitals, the ground state for $D_2^-(g)$ is the $(1s\sigma_g)^2(2p\sigma_u)^2)_u^+$ state involving two bonding electrons and one antibonding electron. As stated by Massey (4), we should expect only a weakly-bound molecule as compared with $D_2(g)$ for which the ground state has no electrons in an antibonding orbital. We would expect, however, the ground state to be $(1s\sigma_g)^2(1s\sigma_u)$. Our calculated $EA(D_2)$ value is consistent with this viewpoint. Further discussion of the $D_2^-(g)$ ion may be found in Massey (4).

$\Delta_f H(0\ K)$ is converted to $\Delta_f H°(298.15\ K)$ by use of JANAF (2) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $D_2(g)$, $D_2^-(g)$, and $e^-(g)$. $\Delta_f H°(298.15\ K)$ should not be interpreted as a room temperature electron affinity due to inclusion of these enthalpies and to thereshold effects discussed by Rosenstock et al. (3).

Heat Capacity and Entropy

The vibrationa constants for $H_2^-(g)$ are estimated to be the same as in the isoelectronic species He_2^+(5). The vibrational constants for $D_2^-(g)$ are calculated from those of $H_2^-(g)$ using isotopic relations (2). The internuclear distance is estimated to be ~8% larger than that for $He_2^+(g)$. The same relationship appeared to exist for the (N_2^-, NO, O_2^+) isoelectronic series. B_e is calculated from r_e whereas α_e is calculated assuming a Morse function for the ground state.

The ground and excited electronic states are discussed in detail by Massey (4). No excited state contributions are included in this calculation.

Point Group: C_{2v} $\sigma = 2$
Bond Distance: N-D = 1.024 Å
Bond Angle: D-N-D = 103.4°
Product of the Moments of Inertia: $I_A I_B I_C = 5.7948 \times 10^{-119}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ of ND_2(g) was calculated from the JANAF selection (1) for $\Delta_f H°(298.15\ K)$ of NH_2(g), the JANAF thermal functions (1), and the zero point energies of H_2(g), D_2(g), NH_2(g), and ND_2(g). The zero point energies of H_2(g) and D_2(g) were those given by Herzberg and Monfils (2). The zero point energies of NH_2(g) and ND_2(g) were estimated from vibrational frequencies given by Milligan and Jacox (3) who observed the infrared and visible spectrum of matrix-isolated NH_2 and ND_2.

Heat Capacity and Entropy

The bond distance and angle are from the electronic absorption spectrum of NH_2 as summarized by Herzberg (4). The vibrational frequencies for the ground state are from Milligan and Jacox (3); those for the excited state are estimated by comparison with NH_2(1, 4).

The National Bureau of Standards prepared this table (5) by critical analysis of data existing in 1972. Using S°, $C_p°$ and $\Delta_f H°$ selected by NBS (5), we recalculate the table in terms of current JANAF reference states for the elements.

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distances: N-N = [1.230] Å N-D = [1.014] Å

Bond Angle: D-N-N = [100]°

Product of Moments of Inertia: $I_A I_B I_C = 3.8165 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(N_2D_2, g, 298.15\ K)$ was estimated from $\Delta_f H°(N_2H_2, g, 298.15\ K) = 50.9 \pm 5$ kcal mol^{-1}, given in the JANAF Thermochemical Tables (1), the appropriate thermal functions (see tables for N_2D_2, H_2, D_2, and N_2H_2, 1) and the estimated zero point energies. The zero point energies for $H_2(g)$, $D_2(g)$ are those given by Herzberg and Monfils (2). The zero point energies for $N_2D_2(g)$ and $N_2H_2(g)$ are taken to be one half the sum of the vibrational frequencies given above and for $N_2H_2(g)$ (1).

Heat Capacity and Entropy

The bond distances and angle are assumed the same as were obtained from a quantum mechanical calculation for N_2H_2 by Wheland and Chen (3). The principal moments of inertia are: $I_A = 0.5832$, $I_B = 2.1780$, $I_C = 2.7612 \times 10^{-39}\ g\ cm^2$. The infrared spectrum of $N_2H_2(g)$ has been observed using matrix isolation techniques by Rosengren and Pimentel (4); they also observed absorptions at 1481 and 1058 cm^{-1} attributed to trans-HNND and at 946 cm^{-1} attributed to trans-DNND. For cis-HNNH, they assigned ν_1 or ν_4 = 3074 cm^{-1} and ν_3 = 1279 cm^{-1}. Based on these observations and the vibrational frequencies adopted for $N_2H_2(g)$ (1), the vibrational frequencies for N_2D_2 are estimated.

The National Bureau of Standards prepared this table (5) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (5), we recalculate the table in terms of 1973 fundamental constants (6), 1975 atomic weights (7), and current JANAF reference states for the elements.

Diazene-D_2, Cis (DNND) $D_2N_2(g)$

$S°(298.15\ K) = 198.339\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -246.251 \pm 0.067\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -249.203 \pm 0.067\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}	ν, cm^{-1}
2671.69(1)	1178.33(1)	2788.02(1)

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distance: O-D = 0.958 Å

Bond Angle: D-O-D = 104.45°

Product of the Moments of Inertia: $I_A I_B I_C = 3.9948 \times 10^{-119}\ g^3\ cm^6$

Enthalpy of Formation

Rossini et al. (1) measured the ratio of the heats of formation of $D_2O(\ell)/H_2O(\ell)$. Recalculation of their results using $\Delta_f H°(298.15\ K)$ of $H_2O(\ell) = -68.315 \pm 0.010$ kcal mol^{-1} (see $H_2O(g)$ table (15)), yields $\Delta_f H°(298.15\ K)$ of $D_2O(\ell) - H_2O(\ell) = -2.1098 \pm 0.01492 \times \Delta_f H°[HDO(\ell)-H_2O(\ell), 298.15\ K] \pm .016$ kcal mol^{-1}. Using a value of 32±30 kcal mol^{-1} for the reaction $H_2O(\ell) + D_2O(\ell) = 2\ HDO(\ell)$ from (2) (some justification that the uncertainty may be smaller is given by Van Hook (3), see also HDO table (15)), one obtains $\Delta_f H°[D_2O(\ell)-H_2O(\ell), 298.15\ K] = -2.094 \pm 0.016$ kcal mol^{-1}.

The difference between the heats of vaporization of $D_2O(\ell)$ and $H_2O(\ell)$ at 298.15 K were evaluated as follows. A. By direct calorimetry, Rossini et al. (1) determined the ratio of the heats of vaporization of $H_2O(\ell)/D_2O(\ell)$ at 298.15 K and zero pressure to be 0.969503±0.00070. B. Bartholome and Clusius (4) determined the heat of vaporization of $D_2O(\ell)$ by direct calorimetry at 0°C. Recalculation of their results, using the energy equivalent of a Bunsen ice calorimetergiven by (5) (compression correction assumed zero) and neglecting gas imperfection corrections, yields 12.637±0.026 kcal mol^{-1}. The heat of vaporization of $D_2O(\ell)$ at 25°C was calculated using a heat of fusion of $D_2O(\ell)$ selected by (6) and (7), the condensed phase of heat capacity data of $D_2O(\ell)$ given by Long and Kemp (8) and the gas phase thermal functions of Friedman and Haar (see next section). C. The difference in heats of vaporization of $D_2O(\ell)$ and $H_2O(\ell)$ was derived by differentiating the formula given by Jones (9) (see (10) for a comparison with other measurements) for the ratio of the vapor pressures of $H_2O(\ell)/D_2O(\ell)$ as a function of temperature and assuming negligible corrections for gas imperfection (see (11), however).

Source	Method	$\Delta_{vap}H°[D_2O(\ell)-H_2O(\ell), 298.15\ K]$, kcal mol^{-1}
Knowlton, Johnston, Rossini	Calorimetry	0.331±0.008*
Bartholome and Clusius	Calorimetry	0.340±0.028*
Jones	Vapor Pressure	0.307±0.020

*Calculated from $\Delta_{vap}H°(298.15\ K)$ of $H_2O(\ell) = 10.520 \pm 0.002$ kcal mol^{-1} (12).

Selecting 0.331±.008 kcal mol^{-1} for the difference in the heats of vaporization, one obtains -1.763±0.018 kcal mol^{-1} for $\Delta_f H°(298.15\ K)$ of $D_2O(g)-H_2O(g)$. The "spectroscopic" value for this difference was calculated to be -1.768±0.015 kcal mol^{-1} based on the zero point energies given by Hulston (13) for $H_2O(g)$ and $D_2O(g)$, and by Herzberg and Monfils (14) for $H_2(g)$ and $D_2(g)$, and the appropriate thermal functions ($H_2O(g)$, H_2(ref. st.), D_2(ref. st.), $D_2O(g)$ (15)). To close the consistency check, the "spectroscopic" value of $\Delta_f H°(298.15\ K)$ of $D_2O(g)$ minus HDO(g) is -0.916±0.0015 kcal mol^{-1} and the "nonspectroscopic" value for this difference (see HDO table, reaction A (15)) is (-1.763±0.0018) + (0.846±0.006) = -0.917±0.019 kcal mol^{-1}. The average value of -1.766±0.016 kcal mol^{-1} for $\Delta_f H°(298.15\ K)$ of $D_2O(g) - H_2O(g)$ and $\Delta_f H°(298.15\ K)$ of $H_2O(g) = -57.795 \pm 0.010$ kcal mol^{-1} (12) are used to obtain $\Delta_f H°(298.15\ K)$ for $D_2O(g) = -59.561 \pm 0.016$ kcal mol^{-1}.

Heat Capacity and Entropy

The thermodynamic functions of this table are analogous to those in the JANAF table for $H_2O(g)$ (15); both tables are taken from Freidman and Haar (16). Friedman and Haar applied their non-rigid-rotor, anharmonic-oscillator treatment (with vibrational-rotational coupling terms and low-temperature rotational corrections) to the infrared-spectra analyses of Benedict et al. (17), and of Benedict et al. (18). In the present table for D_2O, the values of $C_p°$ of Friedman and Haar between 4000 and 5000 K were extrapolated linearly (except with a term in T^{-2}) from 5000 to 6000 K.

The National Bureau of Standards prepared this table (19) by critical analysis of data existing in 1972. Using S°(298.15 K) and $C_p°$ values selected by NBS (19), we recalculate the table in terms of the current JANAF reference states for the elements (15).

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_{2v}
Bond Distance: S-D = 1.328 Å
Bond Angle: D-S-D = 92.2°
Product of the Moments of Inertia: $I_A I_B I_C = 0.3445 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(D_2S, g, 298.15\ K)$ was determined by Kapustinskii and Kankovskii (1) to be -5.692 ± 0.06 kcal mol^{-1} (recalculated) from the reaction: $(a+b)\ D_2S(g) + (1.5a+0.5b)\ O_2(g) = a\ SO_2(g) + (a+b)\ D_2O(g) + b\ S(rhombic)$. The difference of $\Delta_f H°(D_2S, g, 298.15\ K)$ minus $H_2S(g)$ for their work was calculated using their results for $\Delta_f H°(H_2S, g, 298.15\ K)$, -4.92 ± 0.08 kcal mol^{-1} (recalculated), in the hope of eliminating possible systematic error due to uncertainty in the product formed.

The "spectroscopic" value of $\Delta_f H°(D_2S, g, 298.15\ K)$ minus $H_2S(g)$ was calculated from the appropriate thermal functions (see H_2, D_2, H_2S, 5) and the zero point energies of $H_2S(g)$, $D_2S(g)$ (2, 3), $D_2(g)$ (4), and $H_2(g)$ (4).

The equilibrium data of Grafe et al. (5) for the exchange reaction $H_2(g) + D_2S(g) = D_2(g) + H_2S(g)$ were analyzed by third and second law methods.

Source	$\Delta_f H°(298.15\ K)$ of $D_2S(g) - H_2S(g)$, kcal mol^{-1}
Kapustinskii and Kankovskii (1)	-0.771±0.10
Spectroscopic (2, 3, 4)	-0.810±0.01
Grafe, Clusius, and Kruis (5) Third Law	-0.826±0.05
Second Law	-0.887±0.02

A weighted average of -0.81±0.02 kcal mol^{-1} was selected for $\Delta_f H°(298.15\ K)$ of $D_2S(g)$ minus $H_2S(g)$ and was added to the selected value of $\Delta_f H°(298.15\ K)$ of $H_2S(g)$ (6) to determine $\Delta_f H°(298.15\ K)$ of $D_2S(g)$.

Heat Capacity and Entropy

The thermodynamic functions were estimated from those in the present table for $H_2S(g)$ (6) by adding those for $D_2S(g)$ and subtracting those for $H_2S(g)$, where both the added and subtracted functions were generated using the rigid-rotor harmonic oscillator approximation. In this calculation the molecular constants for D_2S were taken from reference (2).

The National Bureau of Standards prepared this table (7) by critical analysis of data existing in 1972. Using S°(298.15 K) and $C_p°$ values selected by NBS (7), we recalculate the table in terms of the current JANAF reference states for the elements.

Ground State Quantum Weight: 1 σ(external) = 3

Point Group: C_{3v} σ(internal) = 2

Bond Length: N-D = 1.0124 Å

Bond Angle: 106.67°

Product of the Moments of Inertia; $I_A I_B I_C = 2.5775 \times 10^{-118}\ g^3\ cm^6$

Enthalpy of Formation

A "spectroscopic" value for the difference in $\Delta_f H°(298.15\ K)$ of $ND_3(g)$ minus $NH_3(g)$ of -3.029±0.01 kcal mol^{-1} was calculated from the appropraite thermal functions (see H_2, D_2, NH_3 (6, 7)), zero point energies of $ND_3(g)$ and $NH_3(g)$ (1, 2), and the zero point energies of $H_2(g)$ and $D_2(g)$ given by Herzberg and Monfils (3).

Analysis of the equilibrium data of Schulz and Schaefer (4) for K°p (1 atm, 660-773 K) for $1/2N_2(g) + 3/2D_2(g) = ND_3(g)$ gave the following:

	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}	Drift cal K^{-1} mol^{-1}	$\Delta S°$(obsv.-calc., 298.15 K)
third law	-13.80	-1.2	----
second law[a]	-13.0±0.38	--	+1.3±0.5 cal K^{-1} mol^{-1}

[a]Asuming $\Delta C°_p$=1.237-0.00608(T-700) cal K^{-1} mol^{-1}

Using the results from the same authors' data for $NH_3(g)$ (6), one obtains a difference in $\Delta_f H°(298.15\ K)$ for $ND_3(g)$ minus $NH_3(g)$ of -2.93±0.14 kcal mol^{-1} (third law) and -2.22±0.4 kcal mol^{-1} (second law). The third law value agrees with the "spectroscopic" value within combined uncertainty intervals.

A value of -3.03±0.1 kcal mol^{-1} was added to the JANAF selection for $\Delta_f H°(298.15\ K)$ of $NH_3(g)$, -10.97±0.10 kcal mol^{-1} (5, 6), to obtain $\Delta_f H°(298.15\ K)$ of $ND_3(g)$.

Heat Capacity and Entropy

The thermodynamic functions were estimated from those in the present table for $NH_3(g)$ (6) by adding those for $ND_3(g)$ and subtracting those for $NH_3(g)$, where both the added and subtracted functions were generated using the rigid-rotor harmonicoscillator approximation. In this calculation the molecular constants for ND_3 were taken from Duncan and Mills (1) and Benedict and Plyler (2).

The National Bureau of Standards prepared this table (7) by critical analysis of data existing in 1972. Using S°, $C°_p$ and $\Delta_f H°$ selected by NBS (7), we recalculate the table in terms of current JANAF reference states for the elements.

Heat Capacity and Entropy

As shown by Sommerfeld (1), the electron gas is a degenerate *Fermi-Dirac gas and its properties* will differ from the classical (Boltzmann) gas. These deviations will increase as the temperature decreases or as the density increases (2,3). Due to the low mass of the electron, these departures from classical behavior will persist to higher temperatures and lower densities than for atomic systems. Under conditions of 1 atm pressure, Gordon (3) showed that the deviation of the Fermi-Dirac gas from the Boltzmann gas is negligible above 1250 K. Below this temperature the deviation between classical and quantum statistics will be significant; Mitchell (4) calculates $S°(298.15\ K) = 22.72\ J\ K^{-1}\ mol^{-1}$ for the Fermi-Dirac gas compared to the classical value of $20.87\ J\ K^{-1}\ mol^{-1}$ for a pressure of 1 atm.

Despite these known deviations we have chosen to present the classical (Boltzmann) values here since the primary purpose of this table is to serve as a reference state for the calculation of tables of thermodynamic properties for atomic and molecular ions. When ionization equilibria are considered, the density (or partial pressure) of the electron gas will be extremely low except at very high temperatures. At an electron partial pressure of 10^{-6} bar, the deviation between classical and quantum statistics will be significant only below 5 K (3). Deviations from classical statistics are encountered at about this same temperature in some atomic and molecular systems at 1 bar pressure; these are usually ignored since the deviations in the enthalpy and entropy are quite small. Therefore, although this ideal-gas table has the formalism of 1 bar as the standard reference state, it should not be applied to real systems where the electron partial pressure exceeds 10^{-6} bar. An equivalent statement is that the electron gas will behave as an ideal gas only at electron partial pressures less than about 10^{-6} bar, with deviations from ideal gas behavior at higher pressures as a result of the departure from classical statistics.

The thermodynamic functions are calculated here via *Boltzmann statistics assuming the electron* gas to be an ideal monatomic gas with two equivalent spin states. The relative ionic mass is the electron rest mass as reported in the 1973 CODATA fundamental constants (5). The first uncertainty in $S°(298.15\ K)$ represents the uncertainty in the fundamental constants and electron rest mass (i.e., the uncertainty below 10^{-6} bar where classical statistics can be applied) while the value given in parenthesis represents the uncertainty due to the use of classical rather than quantum statistics at 1 bar pressure. Values below 298.15 K are omitted from the table since the classical calculation (at 1 bar pressure) results in negative values of entropy below 109 K (4). The values of the thermodynamic functions agree with those published by Gurvich et al. (6) except for two minor differences. First, the entropy differs by $0.1094\ J\ K^{-1}\ mol^{-1}$ because this table uses a standard state pressure of 1 bar, whereas Gurvich et al. (6) used 1 atm. Second, smaller entropy differences occur due to the use of slightly different values of R.

Enthalpy of Formation

The adopted value for the enthalpy of formation of F(g) is the value proposed by CODATA (1); $\Delta_f H°(F, g, 298.15\ K)$ = 79.38±0.30 kJ mol^{-1}. This value is calculated from the dissociation energy of $F_2(g)$, D_0^0 = 12920±50 cm^{-1} (154.56±0.60 kJ mol^{-1}), obtained from the extensive spectroscopic measurements of Colbourn et al. (2). This value is in satisfactory agreement with the results of the equilibrium measurements of Doescher (3) and the photoionization measurements of Berkowitz et al. (4). It is also in good agreement with the value calculated from the enthalpies of formation (5) and vaporization (6) of HF(ℓ) and the spectroscopic data for the dissociation energy of HF(g) (4, 7, 8). This same value is recommended by Brewer and Winn (9), Huber and Herzberg (10) and Gurvich et al. (13), whereas Wagman et al. (21) adopted a dissociation energy which is approximately 0.76 kJ mol^{-1} smaller.

Additional discussions on the enthalpy of formation may be found in the earlier reviews by the JANAF (11) and NBS (12) groups and a recent review by Gurvich et al. (13). Coxon (14) has summarized the spectroscopic information on the lower electronic states of the halogens as of 1973. The more recent spectroscopic studies are discussed by Colbourn et al. (2).

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore (15, 16). Only two levels are included in the calculation. All other levels (observed and predicted) lie above 100000 cm^{-1}. Our calculations indicate that any reasonable method of filling in the missing levels and cutting off the summation in the partition function (17) has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels. Therefore, we list only the ground state and the first excited state. Extension to higher temperatures may require consideration of the higher excited states and utilization of different fill and cutoff procedures.

The thermodynamic functions at 298.15 K are in agreement with recent CODATA recommendations (1) except for two minor differences. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the monatomic halogens arise due to the use of slightly different values for the relative atomic mass and for R; this table uses R = 8.31441 J K^{-1} mol^{-1}. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren et al. (18), Gurvich et al. (13) and Wagman et al. (21). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which are based on the 1981 scale (19) and the 1973 values (20), respectively.

Enthalpy of Formation

$\Delta_f H°(F^+, g, 0\ K)$ is calculated from $\Delta_f H°(F, g, 0\ K)$ (1) using the spectroscopic value of IP(F) = 140524.5±0.4 cm^{-1} (1681.047±0.005 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ mol^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization potential and appearance potential data.

$\Delta_f H°(F^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(F, g, 0\ K)$ by using IP(F) with JANAF (1) enthalpies, $H°(0\ K)-H°(298.15\ K)$, for F(g), $F^+(g)$, and $e^-(g)$. $\Delta_f H°(F \rightarrow F^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the lowest four excited states; the next lowest level is approximately 164797 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and four excited states, with the energy of these states taken from recent study by Moore (2). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, the fundamental constants, and the position of the four lowest excited states. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (7).

PREVIOUS: CURRENT: June 1982 (1 bar)

EA(F, g) = 3.399 ± 0.003 eV

$S°(298.15\ K)$ = 145.576 ± 0.005 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = -250.67 ± 0.6 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [-255.079] kJ mol^{-1}

Electronic Level and Quantum Weight

State	ϵ_i, cm^{-1}	g_i
$^1S_0$	0.0	1

Enthalpy of Formation

$\Delta_f H°(F^-, g, 0\ K)$ is calculated from $\Delta_f H°(F, g, 0\ K)$ (1) using the adopted election affinity of EA(F) = 3.399±0.003 eV (327.951±0.289 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (10), is based on plasma absorption and plasma emission studies (5, 6). Additional information on $F^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 10) Rosenstock et al. (3) and Massey (4).

$\Delta_f H°(F^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(F, g, 0\ K)$ by using EA(F) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $F^-(g)$, F(g), and $e^-(g)$. $\Delta_r H°(F^- \rightarrow F + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $F^-(g)$ is given by Hotop and Lineberger (2, 10), Rosenstock et al. (3) and Massey (4). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

The entropy at all temperatures (0-6000 K) agrees within 0.001 J K^{-1} mol^{-1} with the values of Gurvich et al. (8) except for one minor difference. The entropy differs by 0.1094 J K^{-1} mol^{-1} *because this table uses a standard-state pressure of 1 bar*, whereas the tabulation of Gurvich et al. (8) is based on 1 atm. The estimated uncertainty is due to uncertainties in the relative ionic mass and the fundamental constants which are based on the 1981 scale (9) and the 1973 values (7), respectively.

Product of the Moments of Inertia: $I_A I_B I_C = 1.4723 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(0\ K)$ is the value derived by Berkowitz et al. (1) from photoionization data which gave 14.34 eV as the threshold of O^+ formation, $HOF + h\nu \rightarrow O^+ HF + e^-$. The threshold of OH^+ formation, 15.07 eV for $HOF + h\nu \rightarrow OH^+ + F + e^-$, yields $\Delta_f H°(O\ K)$ = -21.7 kcal mol^{-1} assuming $\Delta_f H°(OH^+, O\ K)$ = 307.5±0.5 kcal mol^{-1} from Dibeler et al. (2). The latter authors found 18.05 eV for $H_2O + h\nu \rightarrow OH^+ + H^+ + e^-$. Our adopted value for HOF differs by only 2.5 kcal mol^{-1} from the mean $\Delta_f H°(O\ K)$ of H_2O and F_2O, namely -25.3 kcal mol^{-1}.

Heat Capacity and Entropy

Vibrational frequencies are from gas-phase infrared spectra of Appelman and Kim (3); the values are confirmed by IR spectra of HOF isolated in a matrix of N_2 (4). Structural parameters are those derived by Pearson and Kim (5) from centrifugal distortion analysis of mm-wave rotational spectra (5, 6) of HOF and DOF. We use the atomic coordinates (5) to derive the principal moments of inertia are $I_A = 0.1431 \times 10^{-39}$, $I_B = 3.1363 \times 10^{-39}$ and $I_C = 3.2795 \times 10^{-39}$ g cm^2 and their product; the corresponding bond distances are 0.96648 and 1.44215 Å, i.e., slightly longer than the rounded values (5) listed above. The earlier study (6) gave 0.964±0.01 and 1.442±0.001 Å and a bond angle of 97.2±0.6°.

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ may be derived from calorimetric data of Richards and Woolf (1) which yield $\Delta_r H°(298.15\ K) = -14.94 \pm 0.2$ kcal mol^{-1} for $SO_3(\ell)$ + HF (real gas, 1 atm) + $HSO_3F(\ell)$. Using $\Delta_f H°(SO_3, \ell, 0\ K) = -105.41$ (2) and $\Delta_f H°(HF$, real gas, 0 K) = -70.12 (3, 4) kcal mol^{-1}, we derive $\Delta_f H° = -190.5$ kcal mol^{-1} for $HSO_3F(\ell)$ and -180.3 ± 1.5 kcal mol^{-1} for the ideal gas. The latter value agrees well with -179.2 ± 3 kcal mol^{-1} estimated for $HSO_3F(g)$ from the related molecules SO_2F_2 and H_2SO_4 (4). We adopt $\Delta_f H° = -180 \pm 2$ kcal mol^{-1} (-753.120 ± 8.4 kJ mol^{-1}).

Derivation of $\Delta_f H°(g)$ presumes that the heat of vaporization is 10.2 ± 1.0 kcal mol^{-1} at 25°C. Measurements of the heat of condensation (5) yield 12.8 ± 0.8 kcal mol^{-1} for the enthalpy difference between real gas at 164.4°C and the liquid at 25 C. Added to this value should be ± 0.2 kcal mol^{-1} (estimated correction for gas imperfection) and -2.8 kcal mol^{-1} (calculated enthalpy difference for the ideal gas between 25°C and 164.4°C, the approximate normal boiling point).

Other calorimetric data bearing on $\Delta_f H°$ were reported by Lenskii et al. (5) and Woolf (6), but these results are much more uncertain (1) due to experimental error and to inadequate definition of the states of the reactants and products.

Heat Capacity and Entropy

Savoie and Giguere (7) reviewed possible molecular structures and preferred eclipsed (cis) forms, arbitrarily selecting one in which F-S-O-H is coplanar. We adopt this structure since the choice changes the thermodynamic functions very little. Possible structures all have $\sigma = 1$ (C_s or C_1 symmetry) and similar values of the product of the moments of inertia. Bond lengths and angles are estimated by comparison with SO_2ClF (8), SO_2CL_2 and H_2SO_4 (4). These parameters yield O=S-F and O=S-OH angles of 107.56° and principal moments of inertia are: $I_A = 15.9647 \times 10^{-39}$, $I_B = 16.1688 \times 10^{-39}$, $I_C = 16.5588 \times 10^{-39}$ g cm^2.

Vibrational fundamentals are from the assignment of Savoie and Giguere (7) as modified by Chackalackal and Stafford (9). Data include Raman spectra of the liquid (10) and infrared spectra of all three phases (7) plus the superheated vapor (9). Spectra of the superheated vapor helped to clarify the vibrational distinction between the monomer and associated molecules. Savoie and Giguere derived a barrier of about 1.3 kcal mol^{-1} for hindered interal rotation of the OH group and used this to calculate $C_p° = 17.64$ and $S° = 71.38$ cal K^{-1} mol^{-1} at 298.15 K. We calculated $C_p° = 17.98$ and $S° = 71.02$ cal K^{-1} mol^{-1} using the OH-torsional frequency (265 cm^{-1}) instead of hindered rotation.

FLUOROSILANE (SiH_3F) IDEAL GAS M_r = 50.107723

$S°(298.15\ K) = 238.402 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-367.16 \pm 20.9]\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [-376.560 \pm 20.9]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
2206(1)	2209(2)
991(1)	961(2)
875(1)	728(2)

729(2)

Ground State Quantum Weight: [1] $\sigma = 3$

Point Group: C_{3v}

Bond Distances: Si-H = 1.468 Å Si-F = 1.593 Å

Bond Angles: H-Si-H = 110.43° H-Si-F = 108.50°

Product of the Moments of Inertia: $I_A I_B I_C = 3.42403 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

There are no reported experimental studies leading to the heat of formation of $SiH_3F(g)$. We estimate this value via a linear interpolation between the established $\Delta_f H°(298.15\ K)$ values of $SiH_4(g)$ and $SiF_4(g)$ (1). The reasonableness of this approach has been demonstrated by Lapidus et al. (2), Hunt and Sirtl (3), and Seiter and Sirtl (4). Lapidus et al. (2) examined the trends in the thermodynamic properties of halogenated silanes and methanes. Hunt and Sirtl (3) and Seiter and Sirtl (4) studied the chlorinated silanes and proposed a linear $\Delta_f H$ relationship within the sequence $SiH_4(g)$ to $SiCl_4(g)$.

Heat Capacity and Entropy

The adopted vibrational frequencies are from the gas phase infrared spectra of SiH_3F and SiD_3F as documented by Robiette et al. (5). Except for ν_4 and ν_5, these values are within ±3 cm^{-1} of those suggested in the compilation by Shimanouchi (6). In particular, based on earlier work, Shimanouchi (6) suggested ν_4 = 2196 cm^{-1} and ν_5 = 956 cm^{-1}. The work of Robiette et al. (5) is judged to yield more accurate frequencies than the earlier work.

The adopted bond angles and bond distances are obtained from the microwave spectra study on SiH_3F and various isotopic derivatives by Kewley et al. (7). This work is deemed more accurate than earlier studies (8-11). The individual moments of inertia are calculated to be $I_A = 0.9972 \times 10^{-39}\ g\ cm^2$ and $I_B = I_C = 5.8599 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

Gaydon (1) gives 32±12 kcal mol^{-1} for the enthalpy of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants are from Herzberg (2). Rotational constants were estimated using relationships in Herzberg (2). Bond length estimated by comparison of the mercurous halides with thalium and cesium halides.

Enthalpy of Formation

Durie and Gaydon (1) have obtained the dissociation limit (from the spectra) of IF as 23570 cm^{-1}. The first excited states of F and I are 404 and 7598 cm^{-1} above the ground state, respectively. There are two sets of dissociation products possible: $I(^2P_{1/2}) + F(^2P_{3/2})$ or $I(^2P_{3/2}) + F(^2P_{1/2})$. When corrected to the normal atoms, the observed limit gives $D_0{}^0(IF)$ 2.87±0.04 eV or 66.18±0.9 kcal mol^{-1} and 1.98±0.04 eV or 45.66±0.9 kcal mol^{-1} for dissociation energy, respectively. Durie and Gaydon (1) favored the lower value. However, Slutsky and Bauer (2) have pointed out a numerical error in their calculations which removes the chief support for the lower value and presented additional evidence favoring the higher value. More weight was given to the higher value which gives $\Delta_f H°(298.15\ K)$ = -22.648±0.9 kcal mol^{-1} for the reaction $1/2\ I_2(cr) + 1/2\ F_2(g) = IF(g)$.

Heat Capacity and Entropy

All molecular constants were obtained from Evans et al. (3) except r_e = 1.906 Å which was obtained from Cole and Elverun (4) and ground state configuration which was estimated by comparison with that for IBr and ICl from Herzberg (5).

PREVIOUS: December 1965 (1 atm) CURRENT: December 1965 (1 bar)

$S°(298.15\ K) = 66.547 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1131\ K$

$\Delta_f H°(0\ K) = -567.111 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -568.606 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 27.196\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of solution of KF(cr) in water has been measured by several investigators. Their results have been converted to $\Delta_{sol}H°(aq, \infty)$ by Parker (5) and listed in the table below. Using $\Delta_{sol}H°(aq, \infty) = -4.24$, $\Delta_f H°(K^+, aq, \infty, 298.15\ K) = -60.32$ (6), and $\Delta_f H°(F^-, aq, \infty, 298.15\ K) = -79.82\ kcal\ mol^{-1}$ (7), we obtain $\Delta_f H°(298.15\ K) = -135.9 \pm 0.1\ kcal\ mol^{-1}$ ($-568.606 \pm 0.4\ kJ\ mol^{-1}$) which is adopted.

Source	T/K	Concentration Molality	No. of Determinations	$\Delta_{sol}H°(aq, \infty)$ kcal mol^{-1}
(1) Guntz (1884)	291	0.28	1	-3.95
(2) Forcrand (1911)	288	0.50	1	-4.54
(3) Lange and Eichler (1927)	298	3.16 - 0.21	8	-4.24±0.4
(4) Lange and Martin (1937)	298	0.31	1	-4.01

Heat Capacity and Entropy

The low temperature heat capacities, 16-323 K, were measured by Westrum and Pitzer (8). The high temperature enthalpies, 298.15-530 K and 291-1187 K, were determined by Westrum and Pitzer (8), and Lyashenko (9), respectively. However, the high temperature $C_p°$ values derived from both sets appear to be inconsistent with the low temperature $C_p°$ values. The heat capacities derived from the enthalpy data of Westrum and Pitzer are too high (3% at 530 K and less at lower temperatures) to be joined smoothly with their low temperature $C_p°$'s. The adopted enthalpy at 530 K is about 1.4% lower than the reported value. The heat capacity derived from the enthalpy data of Lyashenko is 2.5% lower than the adopted one at 900 K. The differences are smaller at lower temperatures. At 900 K, the adopted enthalpy is 1.3% higher than the reported value. The adopted heat capacities in the temperature range, 323-2000 K, are estimated by graphical comparison with other alkali fluorides and chlorides, and joined smoothly with the low temperature data at 298.15 K.

S°(298.15 K) is derived based on the adopted low temperature heat capacities.

Fusion Data

See the liquid table for details.

Sublimation Data

The value of $\Delta_{sub}H°(298.15\ K) = 241.835\ kJ\ mol^{-1}$ for the process KF(cr) = KF(g) for the process KF(cr) = KF(g) is obtained as the difference between $\Delta_f H°(298.15\ K)$ for KF(cr) and KF(g).

PREVIOUS: December 1963 CURRENT: June 1969

$S°(298.15\ K)$ = [67.634] J K^{-1} mol^{-1}

T_{fus} = 1131 K

$\Delta_f H°(298.15\ K)$ = [-554.467] kJ mol^{-1}

$\Delta_{fus} H°$ = 27.196 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(KF,\ell, 298.15\ K)$ is calculated from $\Delta_f H°(KF, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(1131\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those of the alkali fluorides and chlorides, and is assumed to be constant in the temperature range, 298-3000 K. The $C_p°$ value, 16 cal K^{-1} mol^{-1}, derived from the enthalpy data of Lyashenko (12) appears low and is not adopted.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} has been reported as 1119 (1, 2), 1129 (3, 4), 1131 (5, 6), and 1153 K (7). The value 1131 K is adopted. Kelley (8) evaluated the following freezing-point data of binary systems: KF-AlF_3 (9), KF-K_2SO_4 (10), KF-KCl (11), KF-K_2CO_3 (13), and KF-K_3PO_4 (14), and derived the values of $\Delta_{fus} H°$ (in kcal mol^{-1}) as 5.5, 5.55, 6.51, 7.1, and 7.1, respectively. The best value is recommended as 6.50 kcal mol^{-1}. Other reported $\Delta_{fus} H°$ values are 6.70 (7) and 6.75±0.1 kcal mol^{-1} (12). The value of heat of melting is tentatively adopted as 6.50 kcal mol^{-1}.

Vaporization Data

The boiling point (T_{vap}=1790K) is calculated to be the temperature at which the partial pressures of KF(g) and K_2F_2(g) equal one atmosphere. The composition of the gaseous mixture in equilibrium with KF(ℓ) at T_{fus} is calculated as K_2F_2 21.1% and KF 78.9%. The heat required to vaporize one mole of liquid at T_{vap} is evaluated to be 33.9 kcal mol^{-1} (141.838 kJ mol^{-1}) (141.838 kJ mol^{-1}).

The experimental values for the boiling point are 1778 K (1) and 1771 K (15).

$\omega_e = 426.04\ cm^{-1}$ $\omega_e x_e = 2.43\ cm^{-1}$ $\sigma = 1$
$B_e = 0.27994\ cm^{-1}$ $\alpha_e = 0.002335\ cm^{-1}$ $r_e = 2.17155$ Å

Enthalpy of Formation

The total vapor pressures of KF(g) and K_2F_2(g) over KF(cr, ℓ) have been determined by many investigators using the boiling point (1, 2, 5), Knudsen-effusion (3), transpiration (4), and torsion-effusion (6) methods. A method of trial and error is employed to select the appropriate values for $\Delta_{sub}H°$(KF, cr, 298.15 K) and $\Delta_{vap}H°$(KF, ℓ, 298.15 K) such that by use of these two values and $\Delta_r H°(298.15\ K) = 50\ kcal\ mol^{-1}$ for the reaction $K_2F_2(g) = 2\ KF(g)$ and the Gibbs energy functions for KF(cr), KF(ℓ), KF(g), and K_2F_2(g), the calculated total pressures of KF(g) and K_2F_2(g) are consistent with the measured ones. Adopting $\Delta_{sub}H°(298.15\ K) = 57.8$ and $\Delta_{vap}H°(298.15\ K) = 54.42\ kcal\ mol^{-1}$, we evaluate the partial pressures of KF(g) and K_2F_2(g) from the reported total pressure measurements. Based on the derived partial pressures for KF(g), the enthalpy changes for the processes: A. KF(cr) = KF(g), and B. KF(ℓ) = KF(g) are calculated by the 2nd and 3rd law methods. Using the 3rd law $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(298.15\ K) = -135.90$ and $-132.519\ kcal\ mol^{-1}$ for KF(cr) and KF(ℓ), respectively, we obtain the $\Delta_f H°(298.15\ K)$ for KF(g). The results are presented in the table below.

The dissociation energy of KF(g) has been determined as $117 \pm 8\ kcal\ mol^{-1}$ by flame photometry by Page and Sugden (7), and Bulewicz, Phillips, and Sugden (8), yielding $\Delta_f H°(KF, g, 298.15\ K) = -77.6 \pm 8\ kcal\ mol^{-1}$. Barrow and Caunt (9) measured the fluctuation bands in the ultraviolet absorption spectra of KF and reported the upper limit for the D_0^0(KF, g) value to be 121.8 $kcal\ mol^{-1}$ which leads to $\Delta_f H°(KF, g, 298.15\ K) = -81.4\ kcal\ mol^{-1}$ as the lower limit. Gaydon (10) reported $D_0^0 = 116.9 \pm 4.6\ kcal\ mol^{-1}$ for KF(g). The corresponding value of $\Delta_f H°(298.15\ K)$ is calculated as $-77.5 \pm 4.6\ kcal\ mol^{-1}$.

The enthalpy of formation for KF(g) at 298.15 K is adopted as $-78.1 \pm 0.5\ kcal\ mol^{-1}$.

* Data points calculated from the given vapor pressure equation.

** Only the data point at 1233 K is adopted for evaluation.

Heat Capacity and Entropy

The rotational transition spectrum of KF(g) has been measured in the millimeter- and submillimeter-wave region with a high resolution molecular-beam absorption spectrometer by Veazey and Gordy (15). From the derived potential constants the vibrational constants were calculated. The reported values for ω_e, $\omega_e x_e$, B_e, α_e and r_e are adopted.

Other values of ω_e reported are (in cm^{-1}): 390±39 (11), 405±25 (9), 429±3 (12), and 426±4 (13). The value of $\omega_e x_e$ has been determined as 1.45 cm^{-1} by Barrow and Caunt (9), and 2.4 cm^{-1} by Ritchie and Lew (12) and Baikov and Vasilevskii (13). Using the molecular beam electric resonance method, Green and Lew (14) measured the rotational transitions between the J = 0 and J = 1 states of $K^{39}F$ and reported the following values: $B_e = 0.27994\ cm^{-1}$, $\alpha_e = 0.002335\ cm^{-1}$, and $r_e = 2.17144 \pm 0.00005$ Å which are in excellent agreement with the adopted values. By use of the same method, Grabner and Hughes (11) investigated the rotational Stark spectrum of $K^{39}F$ and reported the K-F bond distance for the zeroth vibrational state as 2.55±0.06 Å.

PREVIOUS: June 1969 (1 atm) CURRENT: June 1969 (1 bar)

$S°(298.15\ K) = 35.660 \pm 0.021\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1121.3 \pm 1.0\ K$

$\Delta_f H°(0\ K) = -614.369 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -616.931 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 27.087 \pm 0.021\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpies of solution and reaction of LiF(cr) in water and hydrochloric acid have been measured by many investigators. The reported $\Delta_{sln}H°$ values are listed in the table below. Using $\Delta_f H°(Li^+, aq, \infty, 298.15\ K) = -66.56\ kcal\ mol^{-1}$ (8), and $\Delta_f H°(F^-, aq, \infty, 298.15\ K) = -79.82\ kcal\ mol^{-1}$ (9), we calculate the corresonding $\Delta_f H°(298.15\ K)$ values for LiF(cr). Based on the enthalpy of solution of LiOH(cr) in excess HF solution measured by Sinke (7), the value, $\Delta_f H°(LiF, cr, 298.15\ K) = -146.65 \pm 0.5\ kcal\ mol^{-1}$ is derived. The value of $\Delta_f H°(298.15\ K)$ for LiF(cr) is adopted as $-147.45 \pm 0.2\ kcal\ mol^{-1}$.

*The enthalpy of dilution data of Parker (6) are used to convert $\Delta_r H°$ to $\Delta_\infty H°$.

Heat Capacity and Entropy

Clusius, et al, (10) measured the low temperature heat capacities in the temperature range 19 to 272 K and Clusius and Eichenauer (11) from 10 to 111 K. Below 20 K a number of investigators have reported values of θ_D, and the average value of 729±6 is used here. The high temperature enthalpies from 298.15 K to the melting point 1121.3 K were measured by Douglas and Dever (12), and Voskresenskaya et al. (13). All these data are taken and smoothed by computer to 400 K. Above 400 K the $C_p°$ values are obtained graphically by drawing a smooth line through the data points.

$S°(298.15\ K)$ is derived from the adopted low temperature heat capacities, based on $S°(20\ K) = 0.064\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

See the liquid table for details.

Sublimation Data

The enthalpy of sublimation, $\Delta_{sub}H°(298.15\ K) = 276.144\ kJ\ mol^{-1}$, is calculated as the difference between $\Delta_f H°(298.15\ K)$ for LiF(g) and LiF(cr).

PREVIOUS: December 1963 CURRENT: December 1968

$S°(298.15\ K) = [42.962]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1121.3 \pm 1.0\ K$

$\Delta_f H°(298.15\ K) = [-598.651]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 27.087 \pm 0.021\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(Lif, ℓ, 298.15 K) is calculated from $\Delta_f H°$(LiF, cr, 298.15 K) by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, H°(1121.3 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Douglas and Dever (1) and Voskresenskaya et al. (2) have measured the enthalpies of LiF liquid to 1200 and 1400 K, respectively. Using the reported enthalpy data, a constant heat capacity is derived for each set. The adopted $C_p°$ for LiF(ℓ) is the mean of the two derived heat capacities, and is extended arbitrarily to the temperatures above T_{vap} and below T_{fus}. The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point has been determined by many investigators. See the table below for details. The adopted value, 1121.3±1.0 K, is that reported by Douglas and Dever (1). The heat of melting is the mean of the $\Delta_{fus} H°$ values reported by Douglas and Dever (1) and Voskresenskaya et al. (2).

T_{fus}/ K	Source

Vaporization Data

T_{vap} = 1990 K is the temperature at which the partial pressures of LiF(g), Li_2F_2(g), and Li_3F_3(g), in equilibrium with LiF(ℓ), equal one atmosphere. The vapor composition at the boiling point is evaluated as LiF 69%, Li_2F_2 26.6%, and Li_3F_3 4.4%. The heat required to vaporize one mole of liquid to form 0.739 mole of vapor mixture of the above composition at T_{vap} is calculated to be 35.08 kcal mol^{-1} (146.775 kJ mol^{-1}).

The value of T_{vap} for LiF(ℓ) has been reported to be 1943 and 1949 K by Ruff et al. (3) and von Wartenberg and Schulz (1), respectively, which were obtained by extrapolation of their vapor pressure data, measured by the boiling point method.

LITHIUM FLUORIDE (LiF) IDEAL GAS M_r = 25.939403

$S°(298.15\ K) = 200.278 \pm 0.008\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -340.575 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -340.787 \pm 8.4\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 914.33\ cm^{-1}$ $\omega_e x_e = 8.00\ cm^{-1}$ $\sigma = 1$
$B_e = 1.3588\ cm^{-1}$ $\alpha_e = 0.0203\ cm^{-1}$ $r_e = 1.5631$ Å

Enthalpy of Formation

The molecular species produced on vaporization of lithium fluoride have been studied by many investigators during the last ten years. The occurrence of dimer and trimer molecules in addition to the monomer has been established by use of mass spectrometric (4, 7, 8), torsion effusion (3, 6), molecular beam (9, 10) and transpiration (11) methods. To evaluate $\Delta_{vap}H°(LiF, g)$ we have used a trial and error variation of $\Delta_{sub}H°$ and $\Delta_{vap}H°$ for the monomer, dimer and trimer in order to obtain reasonable agreement with the observed total pressures, 997-1939 K, (1, 2, 3, 5, 6). Using, as guidelines, these total pressures and the equilibrium data for dimer and trimer (see these tables), we adopt $\Delta_{sub}H°(298.15\ K)$ = 66.0, 69.57 and 79.73 and $\Delta_{vap}H°(298.15\ K)$ = 61.63, 60.83 and 66.62 kcal mol^{-1} for LiF, Li_2F_2 and Li_3F_3, respectively. The adopted value $\Delta_{sub}H°(1000\ K)$ = 63.1 kcal mol^{-1} is in agreement with the reported values: 64.8±2 (12), 63.6±1 (6) and 63.0±1.5 kcal mol^{-1} (8) at 1000 K.

A 2nd and 3rd law analysis of the total pressure data is given below. Monomer pressures for this analysis are obtained by deducing dimer and trimer pressures calcualted from JANAF free energy functions and the adopted values of $\Delta_{sub}H°(298.15\ K)$ and $\Delta_{vap}H°(298.15\ K)$.

The vapor pressure data reported by Eisenstadt et al. (9, 10) are too low and so not consistent with the others and are not used for evaluation. The transpiration data of Sense and Stone (11) and Knudsen-effusion data of Evseev et al. (13) are not considered for analysis because of the complications involved in converting the report apparent pressures to the real total pressures of the gaseous mixtures containing monomer, dimer and trimer.

Herzberg (14) and Gaydon (15) reported the dissociation energies (D_0^0) of LiF(g) to be $\leq$ 6.6 and 5.95±0.3 eV, respectively. Using these D_0^0 values, we derive $\Delta_f H°(LiF, g, 298.15\ K)$ as -95.9 and -80.9±6.9 kcal mol^{-1}. By use of flame-photometric method, Page and Sugden (16) and Bulewicz et al. (17) gave D_0^0 = 141 and 136±8 kcal mol^{-1} kcal mol^{-1}, yielding $\Delta_f H°(LiF, g, 298.15\ K)$ = -84.7 and -79.7±8 kcal mol^{-1}.

*Data points are calculated from the given vapor pressure equation.
†Reaction I: LiF(ℓ) = LiF(g); II: LiF(cr) = LiF(g).

Heat Capacity and Entropy

The infrared spectrum of LiF(g) and microwave spectrum of Li^6F have been observed by Vidale (19) and Wharten and Klemperer (21), respectively. The reported vibrational and rotational constants for Li^7F and Li^6F(g) are adopted and corrected to the average isotopic species. Veazey and Gordy (18) measured the rotational transitions of Li^7F with a high resolution molecular-beam absorption spectrometer. By use of the electric resonance method of molecular beam spectroscopy, Braunstein and Trischka (22) observed the transitions between v = 0 and v = 1 vibrational states. The infrared spectrum of LiF(g) have also been measured by Vasilevskii and Baikov (20).

Ground State Quantum Weight: [1] $\sigma = 1$

Point Group: C_s

Bond Distance: Li-O = [1.59] Å F-O = [1.41] Å

Bond Angle: F-O-Li = [104]°

Product of the Moments of Inertia: $I_A I_B I_C = [4.21997 \times 10^{-116}]\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(LiFO, g, 298.15\ K)$, is calculated from $\Delta_r H°(298.15\ K) = 139\ kcal\ mol^{-1}$ for the reaction LiFO(g) = Li(g) + F(g) + O(g) where the value of $\Delta_r H°(298.15\ K)$ is estimated to be the sum of the F-O and Li-O bond energies. The values of the F-O and Li-O bond energies are obtained from those in $F_2O(g)$ and $Li_2O(g)$ molecules, respectively.

Heat Capacity and Entropy

The F-O and Li-O bond distances are assumed to be the same as those in $F_2O(g)$ and $Li_2O(g)$ molecules, respectively. The F-O-Li bond angle and vibrational frequencies are estimated by comparison with the corresponding values for the same oxide molecules. The three principal moments of inertia are: $I_A = 1.2732 \times 10^{-39}$, $I_B = 5.1556 \times 10^{-39}$ and $I_C = 6.4288 \times 10^{-39}$ g cm^2.

Enthalpy of Formation

We calculate $\Delta_f H°(MgF, g, 298.15\ K) = -56.6 \pm 2.0$ kcal mol^{-1} from an adopted. $\Delta_{at} H°(MgF, 298.15\ K) = 110.7 \pm 2$ kcal mol^{-1} which is derived from a 3rd law analysis of three sets of mass spectral-equilibrium data reported by Murad et al. (1) and Hildenbrand (2). Also included in the analysis are independent mass spectrometer-equilibrium measurements on MgF(g) by Ehlert (3, 4).

(D) 2 MgF(g) = Mg(g) + MgF_2(cr)

[a]One point rejected due to failure of a statistical test.
[b]Free-energy functions (FEF) for TlF(g) are calculated from spectral data; (5); FEF for Tl(g) are from Hultgren (6).
[c]3rd law Values; all auxillary $\Delta_f H°(298.15\ K)$ from JANAF Thermochemical Table (8) except for Tl and TlF (7).

We dismiss the measurements of Ehlert (3) and Ehlert et al. (4) since our analyses show that their equilibrium data most likely contain temperature dependent errors. Furthermore, their results (3, 4) yield $D_0{}^0$ values which are less than that predicted by the Rittner ionic model. Krasnov and Karaseva (9) have applied this potential function to all the alkaline earth monohalides and found that it establishes a lower limit for $D_0{}^0$. Recalculation of their results (9) sets $\Delta_{at} H°(MgF, 298.15\ K) \geq 110.4$ kcal mol^{-1}. Application of this ionic model to MgF is justified since the spin densities calculated from the ESR spectra (10) of matrix-isolated MgF show that the molecule is indeed highly ionic.

Trends in the well-established values of the ratio $\Delta_{at} H°(MX, 298.15\ K)/\Delta_{at} H°(MX_2, 298.15\ K)$ for the majority of the alkaline earth halides (8) suggests a value for MgF/MgF_2 which is less than or equal to 0.45. This sets the upper limit of $\Delta_{at} H°(MgF, 298.15\ K)$ at 111 kcal mol^{-1} when $\Delta_{at} H°(MgF_2, 298.15\ K) = 246.7$ kcal mol^{-1} (8). If MgF_2(g) is linear then the maximum $\Delta_{at} H°(298.15\ K)$ value increases to 112.6 kcal mol^{-1} suggesting a possible uncertainty in the adopted $D_0{}^0$ of ± 2 kcal mol^{-1}. Our adopted results give $\Delta_{at} H°(MgF, 298.15\ K)/\Delta_{at} H(MgF_2, 298.15\ K) = 0.44_9$.

Our selected thermochemical $\Delta_{at} H°(298.15\ K)$ value converted to 0 K is 4.76 ev (109.8 kcal mol^{-1}). Other values for $D_0{}^0$ which were considered but believed less reliable are (all in ev 4.0 (11), 5.0 or 4.7 (11) and 4.2 (12). These spectroscopic values have been derived from linear Birge-Sponer extrapolations of the ground state ($X^2\Sigma^+$) and first excited state ($^2\pi$) vibrational levels. We obtain $D_0{}^0 = 3.2_2$ eV from a linear Birge-Sponer extrapolation with our adopted ground state vibrational constants. This value adjusts to 3.59 eV when corrected for the ionicity (2) of the Mg-F bond. The corrected $D_0{}^0$ value is 1.2 eV less than the thermochemical result. This discrepancy is most likely due to the use of an inaccurate value for the anharmonic constant, $\omega_e x_e$, in the Birge-Sponer extrapolation. The use of lower reported values (12, 15) for $\omega_e x_e$ brings the spectroscopic and thermochemical $D_0{}^0$ values into much better agreement but leaves the thermodynamic functions for MgF unaltered. In addition, Singh et al. (13) have employed a method to fit an electronegative potential energy function to the expermimental potential energy curves which yields $D_0{}^0 = 4.45$ eV. This value agrees with our results within probable error limits.

Heat Capacity and Entropy

The electronic levels and vibrational-rotational constants are taken from the compilation of Rosen (5). Values of these constants, tabulated for $Mg^{24}F$, are corrected for the natural isotopic abundances of magnesium. The value of α_e listed by Rosen for the $C^2\Sigma^+$ state is incorrect. The rotational constants are based on an analysis (14) of the rotational structure in the bands of the A-X, B-X, and C-X systems. Barrow and Beale (14) used the Pekeris relation (12) to calculate $\omega_e x_e$ values from their spectroscopic α_e's. These $\omega_e x_e$ values were combined with $\Delta G_{1/2}$ values to give ω_e. These estimates of ω_e and $\omega_e x_e$ differ somewhat from those obtained from a vibrational analysis (15) of band head measurements. However, thermodynamic functions calculated with the alternate set of vibrational constants are not significantly different from those adopted here. The uncertainty in the $\omega_e x_e$ values is large, probably near ±1 cm^{-1}. The partition function $Q = Q_t \Sigma Q_r{}^i Q_v{}^i g_i \exp(-C_2 \epsilon_i/T)$ is used to calculate the thermodynamic functions with first-order anharmonic corrections included for Qr and Qv.

Enthalpy of Formation

MgF^+ ionization-efficiency curves obtained from mass spectral observations on the MgF_2 (1) and MgF_2-Al (2) systems are of the two-process type. Evidence (1, 2) has been presented which shows that the low-energy portion (<13 eV) of the curve arises from the direct ionization (A) of MgF(g). These curves also show an inflection point at higher energies (~14 eV) which has been interpreted (1-3) as due to the onset of the dissociative ionization (B) of MgF_2(g). The appearance potentials, in eV, which have been observed for these two processes from measurements on various MgF_2 systems are tabulated below.

Source	Year	System	(A) Direct Ionization	(B) Dissociative Ionization
Berkowitz and Marquart (4)	1962	MgF_2		13.5±0.4
Green et al. (1)	1964	MgF_2		13.6±0.3
Ehlert et al. (2)	1964	MgF_2-Al	7.8±0.3	13.7±0.4
Murad et al. (5)	1966	MgF_2-Tl-Pd	8.0±0.5	
Hildenbrand (6)	1968	MgF_2-Cu	7.5±0.3	
Hildenbrand (3)	1968	MgF_2	7.5±0.5	

(A) $MgF(g) + e^- \rightarrow MgF^+(g) + 2\ e^-$ (B) $MgF_2(g) + e^- \rightarrow MgF^+(g) + F(g) + 2\ e^-$

Both sets of data show the normal scatter (~0.5 eV) expected for such measurements. The mean value (7.7±0.4 eV) of the four AP's for the direct ionization (A) is supported by the spectroscopic ionization potential of 7.68 eV (7). We adopt $\Delta_r H°$ = 177.56± 9 kcal mol^{-1} (7.7 eV) for process (A), and we obtain $\Delta_f H°(MgF^+, g)$ = 121.1±11.0 kcal mol^{-1} when the $\Delta_r H°$ value is combined with $\Delta_f H°(MgF, g)$ = -56.5±2.0 kcal mol^{-1} (8). The fragmentation process (B) is likely to involve unknown kinetic energy factors and would not be expected to yield *as reliable* $\Delta_f H°$ *value as obtained from direct ionization*. However, the mean value (13.58±0.5 eV) of the four AP's for process (B) leads to $\Delta_f H°(MgF^+, g, 0\ K)$ = 121.5±13.0 kcal mol^{-1} which is in remarkably good with the $\Delta_f H°$ value from direct ionization (121.1 kcal mol^{-1}). This implies that the excess kinetic energy of the fragment MgF^+ is small.

Heat Capacity and Entropy

The bond dissociation energy for MgF^+ (108.6 kcal mol^{-1}) is nearly the same as that for MgF(109.8 kcal mol^{-1}, 8) which implies that the bonding in these two molecules is quite similar. Thus, it is reasonable to assume that $r_e(MgF^+) = r_e(MgF)$. We adopt the measured r_e value (1.75 Å) for MgF (8). B_e is calculated from the adopted value for r_e. The value of ω_e is obtained from Badger's rule (9) which is written in the form $\omega_e^2 = 3.159 \times 10^6/\mu(r_e=d_{ij})^3$. Molecular data (8) for NaF, MgF, and MgO are used to determine the constant d_{ij}. Barrow and Caunt (10) have shown that the product $x_e\mu^{1/2}$ is fairly constant within a group of similar molecules. We assume $x_e(MgF^+) = x_e(MgF)$ since $\mu^{1/2}(MgF^+) = \mu^{1/2}(MgF)$. These estimates of ω_e and $\omega_e x_e$ are only slightly different from those observed for MgF (8). α_e is obtained from the other constants assuming a Morse potential function.

Novikov and Gurvich (11) have observed a band system in the emission spectrum of MgF near 54000 cm^{-1}. An analysis of the vibrational structure showed that the system did not belong to any of those known for MgF, and they (11) assigned it to the $^1\Sigma$-$^1\Sigma$ transition of MgF^+. Band systems have appeared in the absorption spectra (12, 13) of MgF which are now known to arise from AlF. A comparison of the vibrational constants reported by Novikov and Gurvich (11) with those for AlF (8) strongly suggests that this system is the $B^1\Sigma$-$X^1\Sigma$ transition of AlF. Barrow (14) has come to the same conclusion.

MgF^+ (8 valence elecrons) is isoelectronic with the alkaline earth monoxides. We estimate the electronic states and levels for MgF^+ by analogy with those for these isoelectronic *molecules* (8), *particularly* MgO. The $^1\pi$-$^3\pi$ splitting of MgO has recently been reported as 900±200 cm^{-1} (15). We believe that our adopted electronic entropies represent minimal values. Probable upper limits for the electronic contributions can be established by decreasing the two lowest triplet levels to 1000 cm^{-1} ($^3\pi$) and 5000 cm^{-1} ($^3\Sigma$) and neglecting the other excited states. This increases the entropy to 65.1 and 78.6 cal K^{-1} mol^{-1} at 1000 K and 4000 K, respectively. The enthalpy is much more uncertain, approaching ±3.0 kcal mol^{-1} at temperatures in excess of 2000 K.

Enthalpy of Formation

The adopted enthalpy of formation at 298.15 K is that derived by Brewer (1) from the high temperature mass spectrometric measurements of equilibria among gaseous molybdenum fluorides by Hildenbrand [2054-2242 K] (2). The value of $\Delta_f H°(0\ K)$ combined with JANAF data (3) for Mo(g) and F(g) gives D_0^0(Mo-F) = 107.9±4 kcal mol^{-1}.

Heat Capacity and Entropy

We use the ground state vibrational frequency of 700 cm^{-1} estimated by Hildenbrand (2) and adopted by Brewer (1). The Mo-F bond distance, 1.82 Å, is the Mo-F bond distance in MoF_6(g) used by Brewer (1). The electronic contributions are assumed to be the same as those for the free gaseous Mo^+ ion, as suggested by Brewer (1). All states up to 17344 cm^{-1} as listed by Moore (4) are included in the calculation. Our thermodynamic functions differ slightly from those reported by Brewer (1) because of the use of non-zero values for $\omega_e x_e$ and α_e. The estimates for $\omega_e x_e$ and α_e are based on the empirical correlations of Calder and Ruedenberg (5).

This table is based on the critical analysis of data existing in 1978 by Brewer (1).

$B_e = [.923]\ cm^{-1}$ $\alpha_e = [.0120]\ cm^{-1}$ $r_e = [1.51\ Å]$

Enthalpy of Formation

The enthalpy of formation is obtained by taking an average of two estimates of the dissociation energy of NF. The first estimate of 3.15 eV (72.4 kcal mol^{-1}) was obtained from Price et al. (1). The second estimate of 70.4 kcal mol^{-1} is obtained by taking one-half the dissociation energy of NF_2(g) calculated from JANAF values. The $\Delta_f H°(298.15\ K)$ for NF(g) was then calculated with auxiliary JANAF data from a dissociation energy of 71.4 kcal mol^{-1}.

Heat Capacity and Entropy

The ω_e value was obtained from infrared studies of Milligan and Jacox (2). The r_e value was estimated from Guggenheimer's (3) relation for single bonded molecules. The anharmonicity constant x_e is estimated by assuming the separation of the vibrational levels to be a linear function of the vibrational quantum number. The α_e value is then calculated using the Morse potential function; B_e is determined from the bond length. The ground state configuration is assumed to be the same as that in NBr.

Ground State Quantum Weight: 1 $\sigma = 1$
Point Group: C_s
Bond Distances: N-O = 1.13 Å N-F = 1.52 Å
Bond Angle: O-N-F = 110.2°
Product of the Moments of Inertia: $I_A I_B I_C = 49.6113 \times 10^{-117}\ g^3\ cm^6$

Enthalpy of Formation

For the reaction $2NO(g) + F_2(g) + 2ONF(g)$, Johnston and Bertin (1) report $\Delta_r H°(298.15\ K) = -74.8 \pm 0.8$ kcal mol^{-1}, determined calorimetrically. This yields -15.7 ± 0.4 kcal mol^{-1} for $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

Stephenson and Jones (2), report the frequencies, obtained from the infrared spectrum, and moments of inertia, obtained from the microwave spectrum. The principal moments of inertia are: $I_A = 0.8778 \times 10^{-39}$ g cm^2, $I_B = 7.0919 \times 10^{-39}$ g cm^2, $I_C = 7.9697 \times 10^{-39}$ g cm^2.

Ground State Quantum Weight: 1 $\sigma = 2$

Point Group: C_{2v}

Bond Distances: N-F = 1.40 Å N-O = 1.21 Å

Bond Angles: O-N-O = 129.5° F-N-O = 115.25°

Product of the Moments of Inertia: $I_A I_B I_C = 6.400639 \times 10^{-115}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of reaction at 25°C for direct synthesis of nitryl fluoride from nitrogen dioxide with fluorine ($NO_2(g) + 1/2\ F_2(g) = NO_2F(g)$) *has been measured calorimetrically as* -33.9 kcal mol^{-1} by Breazeale and MacLaren (1). The enthalpy of formation, $\Delta_f H°(298.15\ K) = -26.0$ kcal mol^{-1}, for $NO_2F(g)$ was then drived. The values of $\Delta_f H°(298.15\ K) = -20 \pm 5$ and -19 ± 2 kcal mol^{-1} were issued in their second and third quarterly tech. reports and have been quoted in the literature by Tschuikow-Roux (2).

Hetherington and Robinson (3) quoted $\Delta_f H° = 26$ kcal mol^{-1} (presumably it has a minus sign) for $NO_2F(g)$ which was derived from the heat of solution measured by Nichols and Robinson (4).

Heat Capacity and Entropy

Smith and Magnuson (5) have measured the moments of inertia from microwave spectrum of $NO_2F(g)$. In order to calculate the bond distances, given as N-F = 1.35 Å and N-O = 1.23 Å, the bond angle O-N-O was assumed to be 125°. The selected bond distances and angle were obtained from Clayton et al. (6). Clayton et al. assumed the bond angle O-N-O in $NO_2F(g)$ should be *the same as that in* $NO_2Cl(g)$ *and then* calculated the bond distances N-F and N-O from Smith and Magnuson (5) data of the moments of inertia.

The selected vibrational frequencies were obtained from the infrared and Raman spectra measurements by Dodd et al. (7). The three principal moments of inertia are: $I_A = 6.3641 \times 10^{-39}$, $I_B = 7.3394 \times 10^{-39}$ and $I_C = 13.7034 \times 10^{-39}\ g\ cm^2$.

Ground State Quantum Weight: [1] σ = 1

Point Group: C_s

Bond Distances: O-N = 1.29 ± 0.05 Å N-O' = 1.39 ± 0.05 Å O'-F = 1.42 ± 0.05 Å

Bond Angles: O-N-O = 125° ± 5° F-O'-N = 105° ± 5°

Angle between NO'F plane and O_2NO' plane = 90°

Product of the Moments of Inertia: $I_A I_B I_C = 3.88611 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

The value, 2.5±0.5 kcal mol^{-1}, for the enthalpy of formation of $FNO_3(g)$ was obtained from Anderson, et al. (1). The value of $\Delta_f H°$ reported by Talakin, et al. (2) was -4.2±0.9 kcal mol^{-1} at 294 K.

Heat Capacity and Entropy

Vibrational frequencies were estimated by comparison with those of $HNO_3(g)$ reported by Palm and Kilpatrick (3). Bond distances and angles were taken from Pauling and Brockway. The three principal moments of inertia are: $I_A = 8.8638 \times 10^{-39}$, $I_B = 18.5651 \times 10^{-39}$, and $I_C = 23.6154\ 10^{-39}$ g cm^2. The possible existence of restricted internal rotation in the molecule was not considered. Thus the calculated values of $C_p°$ and S° may be low.

$S°(298.15\ K) = 51.212 \pm 0.08\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1269 \pm 2\ K$

$\Delta_f H°(0\ K) = -573.013 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -575.384 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 33.346\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpies of solution and reaction of NaF(cr) have been determined by many investigators. Incorporating their reported data with auxiliary $\Delta_f H°(298.15\ K)$ values (1, 2), we calculate the corresponding values of $\Delta_f H°(NaF, cr, 298.15\ K)$. The results are presented in the table below. The adopted $\Delta_f H°(NaF, cr, 298.15\ K)$ is $-137.52 \pm 0.2\ kcal\ mol^{-1}$ ($-575.384 \pm 0.8\ kJ\ mol^{-1}$).

*Reaction A) represents NaF(cr) = NaF(n H_2O) and $\Delta_r H°(298.15\ K) = \Delta_{soln} H°$; B) NaOH($H_2O$, 200 K) + HF($H_2O$, 200 K) + H_2O(NaF·401 H_2O);
C) NaCl(cr) + 1/2 F_2(g) = NaF(cr) + 1/2 Cl_2(g); D) NaCl(cr) + HF(H_2O, 5.716 K) = NaF(cr) + HCl(H_2O, 12.731K);
E) 4 Na(cr) + CF_4(g) = 4 NaF(cr) + C (graphite).

Heat Capacity and Entropy

The low temperature heat capacities, 0.05 - 15 K and 54.01 - 295.86 K, were measured by Harrison et al. (10) and King (11), respectively. These two sets of data are joined smoothly with the high temperature heat capacities at 298 K which were derived from the enthalpy measurements, 406.1 - 1282.2 K, determined by O'Brien and Kelley (12). The $C°_p$ values above 1282.2 K are obtained by linear extrapolation. S°(298.15 K) is calculated using the adopted low temperature heat capacities and S°(54 K) = 0.555 cal K^{-1} mol^{-1}.

Frank (13) commented that the temperature measurements of O'Brien and Kelley (12) seemed to be about 20 K high at 1000 with a smaller error at lower temperatures. A correction for the assumed error in the temperature measurement was used in the previous JANAF table. However, Douglas and Ditmars (14) have questioned this correction, since new enthalpy data for AlF_3 yielded $C°_p$ values in better agreement with the original $C°_p$ values of O'Brien and Kelley than with the corrected values of Frank. The $\alpha \rightarrow \beta$ transition of AlF_3(cr) was found in the range 723 - 6 K, while O'Brien and Kelley selected 727 K based on a point at 728.1 K in the β region and a point at 724.9 K in the pretransition region. Frank's correction yields an error of 9 at 727 K, yet the true error appears to be negligible (<2) for AlF_3(cr). Based on the above reasoning and the comparison of the $C°_p$ curve of NaF(cr) with those of NaCl(cr), LiCl(cr) and LiF(cr) in the temperature range 300 - 1300 K, we adopt the high temperature enthalpy data of O'Brien and Kelley without any correction.

The low temperature heat capacities in the temperature ranges 81 - 190 and 198 - 273 K were also measured by Koref (15); and high temperature enthalpies at temperatures 288 - 1073 and 290 - 1287 K were reported by Krestovnikov and Karetnikov (16), and Lyashenko (17), respectively. They are not used for evaluation.

Fusion Data

See the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K) = 284.93\ kJ\ mol^{-1}$ is calculated as the difference between $\Delta_f H°(298.15\ K)$ for NaF(g) and NaF(cr).

PREVIOUS: December 1963 CURRENT: December 1968

$S°(298.15\ K) = [73.464]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1269 \pm 2\ K$

$\Delta_f H°(298.15\ K) = [-546.204]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 33.346\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(NaF_3, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(NaF, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(1269\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacities of NaF(ℓ) are derived from the enthalpy data, 1287.6 - 1746.5 K, determined by O'Brien and Kelley (1). A glass transition temperature is assumed at 900 K. The heat capacities below 900 K are taken from those for NaF(cr). The $C_p°$ values above 1746.5 K are obtained by extrapolation. The entropy is calculated in a manner analogous to that used for the enthalpy formation.

Fusion Data

The value of T_{fus} has been reported as (K): 1313 (2), 1285 (1), 1270 (3, 4, 5), 1269 (6), 1268 (7, 8, 9), 1267 (10, 11, 12), 1265 (13), 1263 (14), and 1253 (15). We select T_{fus} = 1269 K. The value 1285 K reported by O'Brien and Kelley seems unreasonably high and is not adopted. The cause of this discrepancy is still unresolved (17). The heat of melting is calculated as the difference between the adopted enthalpies for NaF(cr) and NaF(ℓ) at 1269 K. Kelley (18) derived $\Delta_{fus} H°(1265\ K)$ to be 5.82 - 8.43 kcal mol^{-1}, based on 13 sets of molten salts equilibrium data involving NaF. The value $\Delta_{fus} H°(1285\ K)$ = 8.03 kcal mol^{-1} reported by O'Brien and Kelley is not used.

Vaporization Data

T_{vap} = 2060 K is the temperature at which the partial pressures of NaF(g) and Na_2F_2(g) in equilibrium with NaF(ℓ) equal one atmosphere. The vapor composition at T_{vap} is evaluated as NaF 84.8% and Na_2F_2 15.2%. The heat required to vaporize one mole of liquid to form 0.868 mole of vapor mixture of the above composition at T_{vap} is calculated to be 42.1 kcal mol^{-1} (176.146 kJ mol^{-1})

Ruff et al. (16) measured the vapor pressure of NaF(ℓ) in the temperature range of 1699 - 1974 K and reported T_{vap} = 1978 K.

Enthalpy of Formation

The total pressure of NaF(g) and Na_2F_2(g), in equilibrium with NaF(cr, ℓ) at temperatures 1020 - 1974 K, have been determined by many investigators, using manometric (1, 2, 5), torsion-effusion (6, 8), Knudsen-effusion (3, 7), transpiration (4), and molecular-beam velocity-selector (9, 10) methods. In order to evaluate $\Delta_{vap}H°$(LiF, g) we have used a trial and error variation of $\Delta_{sub}H°$ and $\Delta_{vap}H°$ for the monomer and dimer such that the $\Delta_r H°(298.15\ K)$ values derived by the 2nd and 3rd law methods are in reasonable agreement.

Incorporating $\Delta_{sub}H°(298.15\ K) = 68.1$ and 72.7, and $\Delta_{vap}H°(298.15\ K) = 61.12$ and 58.75 kcal mol^{-1} for NaF and Na_2F_2, respectively, with JANAF functions for NaF(cr), NaF(ℓ), NaF(g) and Na_2F_2(g), we derive the partial pressures of NaF monomer from the reported total pressures. Based on the calculated partial pressures of NaF(g), the corresponding enthalpy of vaporization are evaluated by the 2nd and 3rd law methods. Using the 3rd law $\Delta_r H°(298.15\ K)$ and $\Delta_f H°(298.15\ K) = -137.52$ and -130.545 kcal mol^{-1} for NaF(cr) and NaF(ℓ), we obtain values of $\Delta_f H°(298.15\ K)$ for NaF(g). The results are presented in the table below. The $\Delta_f H°$(NaF, g, 298.15 K) value adopted is -69.42 kcal mol^{-1} (-290.453±2.1 kJ mol^{-1}).

Gaydon (11) and Herzberg (12) reported D_0^0 = 114.2±6.9 (4.95±0.3 eV) and ≤ 122.2 kcal mol^{-1} (5.3 eV), respectivley. Using JANAF $\Delta_f H°(298.15\ K)$ values for Na(g) and F(g), we obtain $\Delta_f H°$(NaF, g, 298.15 K) = -70.5±5.8 and ≥ -78.5 kcal mol^{-1}. Employing flame-photometric method, Bulewicz et al. (13) and Page and Sugden (14) derived D_0^0 = 121±7 and 119 - 120 kcal mol^{-1} for NaF(g), which lead to $\Delta_f H°$(NaF, g, 298.15 K) = -77.3±7 and -75 to -76 kcal mol^{-1}.

Heat Capacity and Entropy

Veazey and Gordy (15) have measured the rotational transitions of NaF in the millimeter- and sub-millimeter-wave region with a high-resolution molecular-beam absorption spectrometer. The derived values of ω_e, $\omega_e x_e$, B_e, α_e and r_e are adopted here.

Using the molecular beam electric resonance method, Bauer and Lew (16) measured the transition between the J = 0 and J = 1 rotational levels of $Na^{23}F^{19}$ in the three lowest vibrational states. Radio-frequency transitions for $Na^{23}F^{19}$ have been observed by Hollowell et al. (19). Infrared spectra of NaF have been analyzed by Snelson and Pitzer (17), Ritchie and Lew (18), and Baikov and Vasilevskii (20). The molecular constants derived by the above authors are similar to the values adopted, except the value ω_e = 550 cm^{-1} (17) which is different from the value 536.1 cm^{-1} reported by Veazey and Gordy (15).

$B_e = [1.148]\ cm^{-1}$ $\alpha_e = [0.020]\ cm^{-1}$ $r_e = [1.30]$ Å

Enthalpy of Formation

Several values have been proposed for the enthalpy of formation of FO(g). Dibeler et al. (1), obtained $D_0^0(FO, g) = 24$ kcal mol^{-1} from electron impact studies. However, theoretical estimates give D_0^0 values in the range 45-56 kcal mol^{-1}. Price et al. (2), estimated 52 kcal mol^{-1} for $D_0^0(FO, g)$.

From a consideration of the central bond energies in FNNF and HNNH with that in HOOH, using all JANAF values of 101, 109 and 50 kcal mol^{-1}, we predict the bond dissocation energy in FO-OF to be 46±4 kcal mol^{-1}, which yields $D_0^0(FO, g) = 51 \pm 2$ kcal mol^{-1}. The average F-O bond dissociation energy in $F_2O(g)$ is 49.8±0.5 kcal mol^{-1}. Also, since there is one less antibonding electron in FO than in F_2, we should expect the F-O bond to be greater than that in F_2(38 kcal mol^{-1}). Thus a median value of $D_0^0(FO, g) = 51.4 \pm 10$ kcal mol^{-1} is adopted here which leads to $\Delta_f H°(FO, 298.15\ K) = 26$ kcal mol^{-1} (108.784±41.8 kJ mol^{-1}).

Heat Capacity and Entropy

The fundamental frequency is obtained by adding 2 $\omega_e x_e$ to the value reported by Arkell et al. (3), from matrix isolation studies. The bond length was taken equal to that in the isoelectronic molecule $O_2^-(g)$. The value of $\omega_e x_e$ was obtained from the Morse potential function and the assumed dissociation energy. The rotational constant α_e was also estimated from the above parameters and the Morse potential curve. The $^2\Pi$ ground state is that predicted by molecular orbital theory and the first excited state would also be $^2\Pi$. By analogy with the isoelectronic $O_2^-(g)$ states, the first excited level was estimated at 29000 cm^{-1}.

PREVIOUS: December 1966 (1 atm) CURRENT: December 1966 (1 bar)

TITANIUM FLUORIDE OXIDE (OTiF) IDEAL GAS M_r = 82.877803

$S°(298.15\ K)$ = [250.667] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [-430.918] kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [-433.211] kJ mol^{-1}

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[880](1)
[300](2)
[740](1)

Ground State Quantum Weight: [2] σ = 1
Point Group: [$C_{\infty v}$]
Bond Distances: Ti-O = [1.62] Å Ti-F = [1.74] Å
Bond Angle: O-Ti-F = [180°]
Rotational Constant: B_0 = [0.170462] cm^{-1}

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as -103 kcal mol^{-1} by Gordon (1). $\Delta_f H°(298.15\ K)$ was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon (1).
