$S°(298.15\ K) = [339.554 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -271.66 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -274.89 \pm 6.3\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[111](1)
[31](2)
[219](1)

Ground State Quantum Weight: [1] $\sigma = 2$

Point Group: $D_{\infty h}$

Bond Distance: Sr-I = 3.03 ± 0.03 Å

Bond Angle: I-Sr-I = [180]°

Rotational Constant: $B_0 = 0.007234\ cm^{-1}$

Enthalpy of Formation

Peterson and Hutchison (1, 2) used a weight loss Knudsen effusion technique to observe vapor pressures of the liquid at 20 temperatures ranging from 1061 to 1308 K. Our 2nd and 3rd law analyses of these data give $\Delta_{vap}H°(298.15\ K)$ (2nd law) = 65.72 ± 1.48 kcal mol^{-1} and $\Delta_{vap}H°(298.15\ K)$ (3rd law) = 65.48 ± 0.68 kcal mol^{-1} with a drift of -0.2 ± 1.2 cal K^{-1} mol^{-1}. We adopt $\Delta_{vap}H°(298.15\ K)$ = 65.5 ± 0.7 kcal mol^{-1} and combine this with the adopted enthalpy of formation of the liquid to obtain $\Delta_f H°(SrI_2, g, 298.15\ K)$ = -65.7 ± 1.5 kcal mol^{-1}.

Heat Capacity and Entropy

The bond distance, as determined from an electron diffraction study, is taken from Akishin et al. (3) who also judged that the bond angle was 180° ± 10°. We have assumed a linear structure.

An analysis of the trend of the ratio of the stretching force constants, k(monohalide)/k_1(dihalide), has indicated that $k(SrI)/k_1(SrI_2) = 1$ is a reasonable approximation (4). The bending force constant is taken as 0.01 times the stretching force constant. These approximations have been used by Brewer et al. (5). Our vibrational frequencies calculated from the force constants, using k for SrI calculated from the ground state vibrational frequency given by Rosen (6), are in exact agreement with those calculated by Brewer et al. (5), which are adopted. Other estimates of ν_1, ν_2, and ν_3 are 111, 49, and 220 (7).

We assign an uncertainty of ±2 cal K^{-1} mol^{-1} to the entropy to allow for error in bond angle and vibrational frequency estimates.

TITANIUM IODIDE (TiI_2) CRYSTAL M_r = 301.6890

$S°(298.15\ K) = [122.591 \pm 12.6]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -266.10 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of TiI_2(cr) is calculated from the enthalpy of reaction for the process $2TiI_2(cr) = Ti(cr) + TiI_4(g)$, and the enthalpy of formation of TiI_4(cr). Vapor pressure data for this reaction were reported by Herczog and Pidgeon (1) over the temperature range 750 to 902 K. 2nd and 3rd law analyses of these data give values for $\Delta_r H°(298.15\ K)$ of 60.5±0.8 and 60.85 kcal mol^{-1}, respectively, the 3rd law drift being 0.4±1.0 cal K^{-1} mol^{-1}. The 3rd law $\Delta H°(298.15\ K)$ is used to obtain the adopted value of $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

The estimated heat capacity is that reported by Kelley (2). The value of S°(298.15 K) is estimated from that of $TiCl_2$(cr) and the difference between ionic entropy contributions of Cl^- and I^-.

Sublimation Data

The enthalpy of sublimation of TiI_2(cr) is taken as the difference in the enthalpies of formation of TiI_2(cr) and TiI_2(g) at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta_r G° = 0$ for the reaction $TiI_2(cr) = TiI_2(g)$.

Rotational Constant: B_0 = [0.009111] cm^{-1}

Enthalpy of Formation

The enthalpy of formation of $TiI_2(g)$ is calculated from that of $TiI_2(cr)$ and the enthalpy of vaporization. Vapor pressure data over the temperature range 750 K to 902 K have been reported by Herczog and Pidgeon (1). 2nd and 3rd law analyses of these data give values for $\Delta_{vap}H°(298.15\ K)$ of 51.9 and 58.9 kcal mol^{-1}, respectively. The 3rd law drift for these data is 8.3±1.1 cal K^{-1} mol^{-1}, *with one point rejected due to failure of a statistical test.* The adopted value of $\Delta_f H°(298.15\ K)$ is calculated from the 3rd law enthalpy of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2(g)$, $TiCl_4(g)$, $TiBr_2(g)$, $TiBr_4(g)$ and $TiI_4(g)$. The vibrational frequencies are estimated from a valence force field model. *The force constant K is estimated as 1.0 millidynes/Å* and the constant K_δ/μ^2 is assumed to be 0.05 millidynes/Å.

The electronic levels are assumed to be the same as $TiCl_2(g)$. The levels of $TiCl_2$ are estimated by assuming they correspond to the inverted states of $NiCl_2(g)$ (2). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (3, 4, 5, 6).

ZIRCONIUM IODIDE (ZrI_2) CRYSTAL M_r = 345.0290

$S°(298.15\ K)$ = [150.206] J K^{-1} mol^{-1}

T_{fus} = [700] K

$\Delta_f H°(298.15\ K)$ = [-259.408] kJ mol^{-1}

$\Delta_{fus} H°$ = [25.104] kJ mol^{-1}

Enthalpy of Formation

Estimated from a consideration of $\Delta_f H°(ZrI_4, cr)$ and of the disproportionation data given by Rolsten (1).

Heat Capacity and Entropy

Heat capacity estimated by comparison to the other zirconium halides and titanium halides. Entropy estimated from additive constants.

Fusion and Vaporization Data

$\Delta_{fus} H°$ was estimated. T_{fus}, T_{vap} and $\Delta_{vap} H°$ from Brewer (2).

Zirconium Iodide (ZrI_2) $I_2Zr_1(cr)$

$S°(298.15\ K) = [186.168]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [700]\ K$

$\Delta_f H°(298.15\ K) = [-234.239]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [25.104]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(ZrI_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(700\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The liquid phase heat capacity is estimated. $S°(ZrI_2, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion and Vaporization Data

$\Delta_{fus} H°$ was estimated. T_{fus}, T_{vap} and $\Delta_{vap} H°$ from Brewer (1).

ZIRCONIUM IODIDE (ZrI_2) IDEAL GAS M_r = 345.0290

$S°(298.15\ K)$ = [344.782] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [-63.262] kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [-66.643] kJ mol^{-1}

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[60](1)
[120](1)
[210](1)

Ground State Quantum Weight: [1] σ = 2

Point Group: C_{2v}

Bond Distance: Zr-I = [2.66] Å

Bond Angle: I-Zr-I = 120°

Product of the Moments of Inertia: $I_A I_B I_C$ = 1.072892 x 10^{-111} g^3 cm^6

Enthalpy of Formation

Based upon the estimated value of the $\Delta_f H°$ for the crystal and the appropriate crystal and gas functions.

Heat Capacity and Entropy

Molecular constants were all estimated by comparison to similar molecules of zirconium and titanium. The principal moments of inertia are: I_A = 19.7106 x 10^{-39}, I_B = 223.6596 x 10^{-39} and I_C = 243.3703 x 10^{-39} g cm^2.

Enthalpy Reference Temperature = T_r = 298.15 K Standard State Pressure = p° = 0.1 MPa

MOLYBDENUM IODIDE (MoI_3) CRYSTAL M_r = 476.6535

$S°(298.15\ K) = [195.393 \pm 16.7]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -124.68 \pm 8.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Barnes et al. (1) have measured calorimetrically the enthalpy of formation of $MoI_{2.76}$ by reacting iodine vapor with $Mo(CO)_6$ at 539 K. The products were found to consist of MoI_3, MoI_2, and Mo by chemical analysis. Assuming a difference in the enthalpies of formation of MoI_3 and MoI_2 of 1.5 kcal mol^{-1}, Barnes et al. (1) determined that the $\Delta_f H°(MoI_3, cr, 298.15\ K)$ = -26.2±2.0 kcal mol^{-1}. Brewer (2) has estimated that the difference $\Delta_f H°(MoI_3)-\Delta_f H°(MoI_2)$ may be as large as -5 kcal mol^{-1} and reanalyzed the heat of iodination data with the result $\Delta_f H°(MoI_3, cr, 298.15\ K)/R$ = -15000±1000 K which is adopted. We adopt the estimate of Brewer(2). The assigned uncertainty (±2.0 kcal mol^{-1}) is determined from the product 1000xR which has been rounded to the nearest kcal mol^{-1}.

Heat Capacity and Entropy

The values of $S°(298.15\ K)$ and $C_p°$ over the temperature range 298-1000 K are estimates reported by Brewer (2). We treat the estimated entropy value given as $S°(298.15\ K)/R$ in a manner similar to that for the enthalpy of formation.

Phase Data

Drobot et al. (3) have studied the thermal decomposition of MoI_3 in evacuated sealed ampoules at various temperatures. X-ray diffraction and chemical analyses of the condensed decomposition products showed the existence of a homogeneity range in which the atomic ratio of I/Mo varied from 3.00 to 2.5. The crystal structure of MoI_3 is oP16 (2) in the Pearson classification system.

Decomposition Data

T_{dcm} of 629.5 K is calculated as the decomposition temperature at which the fugacity of iodine is 1 atm for the dissociation reaction $MoI_3(cr) = MoI_2(cr) + 0.5\ I_2(g)$. Saturated vapor pressure measurements by Drobot et al. (3) indicate that $MoI_3(cr)$ decomposes to a non-stoichiometric triiodide phase beginning at a temperature near 363.2 K.

Bond Angle: I-Mo-I = [120]°

Product of the Moments of Inertia: $I_A I_B I_C = [2.237654 \times 10^{-110}]\ g^3\ cm^6$

Enthalpy of Formation

The adopted value of $\Delta_f H°$ at 298.15 K is that estimated by Brewer (1). The estimated value is consistent with the low volatility of solid molybdenum in iodine vapor reported by Schafer et al. (2). The estimated value given by Brewer (1) is $\Delta_f H°(298.15\ K)/R = 22000 \pm 5000$ K. The assigned uncertainty (± 10 kcal mol^{-1}) is determined from the product 5000xR which has been rounded to the nearest kcal mol^{-1}. The value of $\Delta_f H°(0\ K)$ combined with JANAF data (3) for Mo(g) and I(g) gives $\Delta_{at} H°(0\ K) = 189 \pm 11$ kcal mol^{-1} and an average Mo-I bond energy of $\Delta_{at} H°(0\ K)/3 = 63 \pm 4$ kcal mol^{-1}.

Heat Capacity and Entropy

The bond length and vibrational frequencies are values estimated by Brewer (1). A planar structure has been predicted for MoI_3 by Drak and Rosenblatt (4). The electronic contribution is taken to be the same as that for TaO, as estimated by Brewer (1). The levels are taken from the latest JANAF table (3), however, we only include four levels. The principal moments of inertia are: $I_A = I_B = 223.6596 \times 10^{-39}$, and $I_C = 447.3193 \times 10^{-39}$ g cm^2.

Product of the Moments of Inertia: $I_A I_B I_C$ = [1.038908 x 10^{-110}] g^3 cm^6

Enthalpy of Formation

The enthalpy of formation of SiI_3(g) is based on an assumed average bond energy of 58±5 kcal mol^{-1} (1). This average bond energy is that of SiI (g), i.e. $\Delta_{at}H°(SiI_4, g, 0\ K)/4$. The rationale for this assumption is based on the same relationship existing for the silicon chloride and fluoride species (1).

Heat Capacity and Entropy

The molecular structure is assumed to be identical to the SiI_3 group in $SiHI_3$ (1). From this structure we estimate the following principal moments of inertia: $I_A = I_B$ = 173.9077 x 10^{-39}, and I_C = 343.5099 x 10^{-39} g cm^2. The vibrational frequencies are assumed to be those of the SiI_3 group in $SiHI_3$(g).

PREVIOUS: December 1977 (1 atm) CURRENT: December 1977 (1 bar)

$S°(298.15\ K) = [192.464 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$T_{sub} = [1000]\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta H°(298.15\ K) = [-322.17 \pm 20.9]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of TiI_3(cr) is calculated from the free energy of formation at 623 K combined with the increment $\Delta_f G°(623\ K)-\Delta_f G°(298.15\ K)$ and the entropies, $S°(298.15\ K)$, of TiI_2(cr), TiI_3(cr) and TiI_4(g). The free energy of formation, $\Delta_f G°(623\ K)$, is estimated such that $\Delta_r G°(623\ K) = 0$ for the process $2TiI_3(cr) = TiI_2(cr) + TiI_4(g)$. This assumption is based on the observations of Hercog and Pidgeon (1) and Fast (2).

Heat Capacity and Entropy

The heat capacities of TiI_3(cr) and the value of $S°(298.15\ K)$ estimated by Kelley (3) have been adopted.

Sublimation Data

The enthalpy of sublimation of TiI_3(cr) is taken as the difference in the enthalpies of formation of TiI_3(cr) and TiI_3(g) at the sublimation temperature. The sublimation temperature is estimated as the point at which $\Delta_r G° = 0$ for the process $TiI_3(cr) = TiI_3(g)$.

Product of the Moments of Inertia: $I_A I_B I_C$ = 1.322449 x 10^{-110}] g^3 cm^6

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(TiI_3, g, 298.15\ K)$, is estimated from the average Ti-I bond energy. The bond energy is estimated from the corresponding quantities for $TiBr_4(g)$, $TiBr_3(g)$ and $TiI_4(g)$.

Heat Capacity and Entropy

The interatomic distance is estimated from those of TiI_4, $TiCl_4$ and $TiCl_3$. The pyramidal bond angle is estimated by assuming that $TiI_3(g)$ is similar to the group V trihalides. The principal moments of inertia are: $I_A = I_B$ = 191.5028 x 10^{-39} and I_C = 360.6023 x 10^{-39} g cm^2. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} reported by Moore (1).

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

$S°(298.15\ K)$ = [204.585] J K^{-1} mol^{-1}

T_{sub} = [970] K

$\Delta_f H°(0\ K)$ = [-396.545] kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [-397.480] kJ mol^{-1}

Enthalpy of Formation

Larsen and Leddy (1) studied the reaction Zr(cr) + 3 ZrI_4(g) = 4 ZrI_3(cr) in the temperature range 473 to 973 K and pressure range 5 to 15 atm. They present a plot of the fractional reaction, at a number of temperatures, as a function of reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The Gibbs energy function change for this reaction was calculated at 100 K from 500 to 1100 K. At each temperature the equilibrium constant was assumed to be 1, and $\Delta_r H°(298.15\ K)$ accordingly calculated. These values and the enthalpy of formation of ZrI_4(g) [see ZrI_4 table] were used to compute a series of values for the enthalpy of formation of ZrI_3(cr) at 298.15 K. The following table gives representative values at four temperatures.

T/K	K_p	$\Delta_r H°(298.15\ K)$, kcal mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
500	1	-66.0	-80.2
700	1	-90.3	-86.2
900	1	-113.5	-92.1
1100	1	-135.9	-97.7

If one assumes an initial pressure of from 5 to 10 atm. for ZrI_4 and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of ZrI_4 to attain a value of 1 atm. and hence an equilibrium constant of 1. The data of Larsen and Leddy indicate that the reaction proceeds to the extent of 88% at 973 K. From this it was assumed that at around 1000 K the equilibrium constant attains a value of 1 giving -95 kcal mol^{-1} for the enthalpy of formation of ZrI_3 at 298.15 K.

Their data were subjected to a 2nd law calculation but the results are of doubtful value in view of the uncertainty in the attainment of thermodynamic equilibrium at the lower temperature. The limits of error assigned to the enthalpy of formation are ±15 kcal mol^{-1} corresponding to a temperature spread of ±500 in the above table.

Heat Capacity and Entropy

The heat capacity was estimated in the same manner as for $ZrBr_4$(cr) [see $ZrBr_4$(cr) table]. The value θ_D = 60 K and θ_E = 115 K were taken to be the same as those estimated for ZrI_4(cr). The internal contribution was obtained from the estimated ZrI_3 vibrational frequencies and the anharmonicity factor "a" was taken to be 2.5 x 10^{-3}. The specific heat above 300 K was obtained by graphical extrapolation.

For the above estimation, it was assumed that the crystalline lattice is made up of ZrI_3 molecules. However, Holze (2) came to the conclusion that crystalline ZrI_3 is composed of a chain lattice of $(Zr_2I_6)_n$ units. The results of an analysis for a crystalline lattice composed of Zr_2I_6 units would probably not differ significantly from that for a crystalline lattice composed of ZrI_3 units since both are approaching the classical harmonic heat capacity of 12R calories per formula weight of ZrI_3 at relatively low temperatures.

Until more quantitative information becomes available, it is felt that the above analysis gives a fair approximation to the heat capacity of ZrI_3.

Decomposition Data

As described in the "Enthalpy of Formation" section, the temperature of decomposition was assumed to be 1000 ± 500 K.

Liquid Data

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data

The enthalpy of sublimation at 298.15 K was obtained from the difference in the enthalpies of formation of the gas and solid at 298.15 K. The sublimation point was obtained from the free energy crossover between gas and solid.

Enthalpy of Formation

The enthalpies of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides were computed from data issued in these tables. The zirconium-halide bond energy, taken as 1/4 of this enthalpy of formation, was found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it was found that the bond energy of the trichloride was around 7 kcal mol^{-1} greater than that for titanium tetrachloride. This amount was added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, was found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium was determined from this curve and their estimated bond distances.

For zirconium triiodide, the enthalpy of formation from the gaseous atoms was -275 kcal mol^{-1} and from the elements in their standard state, -53 kcal mol^{-1}.

Heat Capacity and Entropy

The measured internuclear distances for the triiodides of phosphorus, arsenic, and antimony were plotted as a function of the atomic weight of these elements and a smooth curve was drawn through the points. The bond distance in ZrI_3 was taken from this plot. The bond angle was assumed to be 101°. The principal moments of inertia are: $I_A = I_B$ = 185.2317 x 10^{-39} and I_C = 336.6703 x 10^{-39} g cm^2.

Force constants for ZrI_3 were estimated from those of the triiodides of phosphorus and arsenic. These were used in a valence force field calculation giving ν_1 = 195, ν_2 = 88, ν_3 = 181, and ν_4 = 65 cm^{-1}. For the fluorides and chlorides of P, As, and Sb, ν_1 is greater than ν_3 but there appears to be a reversal as one goes to the bromides and iodides with ν_3 becoming greater than ν_1. An empirical correlation procedure for ZrI_3 gave ν_1 = 195, ν_2 = 90, ν_3 = 220, and ν_4 = 65 cm^{-1} in which $\nu_3 > \nu_1$. Since $\nu_3 > \nu_1$ for PI_3 and AsI_3, the correlation value for ν_3 was used to represent this frequency in ZrI_3.

PREVIOUS: June 1964 (1 atm) CURRENT: June 1964 (1 bar)

$S°(298.15\ K)$ = [266.061 ± 16.7] J K^{-1} mol^{-1}
T_{dcm} = [293] K

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K)$ = [−123.010 ± 8.4] kJ mol^{-1}

Enthalpy of Formation

We adopt the $\Delta_f H°(298.15\ K)$ value estimated by Brewer (1). This value predicts that MoI_4(cr) is unstable with respect to MoI_3(cr) at temperatures above 293 K (1). This is consistent with the observations of Lewis et al. (2) who found that only the crystalline triiodide is formed by heating pure Mo metal in excess iodine in a sealed tube to 573 K. Brewer's estimated value is given as $\Delta_f H°(298.15\ K)/R$ = −14800±1000 K. The assigned uncertainty (±2 kcal mol^{-1}) is determined from the product 1000xR which has been rounded to the nearest kcal mol^{-1}.

Heat Capacity and Entropy

The values of $C_p°$ and S° at 298.15 K are estimates reported by Brewer (1). We assume a constant $C_p°$ of 32.79 cal K^{-1} mol^{-1} over the temperature range 298–600 K. The value of $S°(298.15\ K)/R$ reported by Brewer (1) is treated in a manner similar to that for the enthalpy of formation.

Phase Data

The preparation of MoI_4(cr) has been reported by Guichard (3) but the sample was impure. The stability range of the tetraiodide appears to be small based on the observations of Lewis et al. (2) who found that MoI_4 could not be formed by heating Mo in excess iodine in a sealed tube to 573 K.

Decomposition Data

Brewer (1) estimated a T_{dcm} of 293 K from free energy data for the dissociation reaction $MoI_4(cr) = MoI_3(cr) + 0.5\ I_2(cr)$. We adopt this value since T_{dcm} appears to lie outside the temperature range selected for our MoI_4(cr) phase table.

Product of the Moments of Inertia: $I_A I_B I_C$ = [6.286307 x 10^{-110}] g^3 cm^6

Enthalpy of Formation

We adopt the $\Delta_f H°(298.15\ K)$ value estimated by Brewer (1). This estimated value is consistent with the low volatility of metallic molybdenum in iodine vapor reported by Schafer et al. (2). Brewer's estimated value is given as $\Delta_f H°(298.15\ K)/R$ = 15000±5000 K. The assigned uncertainty (10 kcal mol^{-1}) is determined from the product 5000xR which has been rounded to the nearest kcal mol^{-1}. Combining the $\Delta_f H°(0\ K)$ value with JANAF (3) data on Mo(g) and I(g), we calculate a heat of atomization $\Delta_{at} H°(0\ K)$ of 228.7±11 kcal mol^{-1} and a mean bond dissociation energy $\Delta_{at} H°(0\ K)/4$=57.2±2.5 kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational frequencies and molecular structural data are estimates taken from Brewer (1). The principal moments of inertia are: $I_A = I_B = I_C$ = 397.6172 x 10^{-39} g cm^2. The electronic levels and degeneracies are those predicted by Brewer (1) for MoF_4(g) from crystal field theory. The upper levels contribute 0.23 cal K^{-1} mol^{-1} to the Gibbs energy function at 6000 K.

Ground State Quantum Weight: [1] σ = [12]
Point Group: [T_d]
Bond Distance: Pb-I = [2.77] Å
Bond Angle: I-Pb-I = [109°28']
Product of the Moments of Inertia: $I_A I_B I_C$ = [8.016506 x 10^{-110}] $g^3\ cm^6$

Enthalpy of Formation

The adopted $\Delta_f H°(0\ K)$ = -52.3±20 kcal mol^{-1} is derived from the atomization energy for the process $PbI_4(g) = Pb(g) + 4\ I(g)$. $\Delta_{at}H°(0\ K)$ = 8.75 eV is estimated from an intercomparison of the lead mono-, di-, and tetra- halides (1). This adopted value for $PbI_4(g)$ is greater than the $\Delta_{at}H°(0\ K)$ value for PbI (g) by a factor of 2.04. The auxiliary values $\Delta_f H°(Pb, g, 0\ K)$ = 46.91 kcal mol^{-1} (1) and $\Delta_f H°(I, g, 0\ K)$ = 25.633 kcal mol^{-1} (1) are used. $\Delta_f H°(PbI_4, g, 298.15\ K)$ = -53.6±20 kcal mol^{-1} is calculated from $\Delta_f H°(0\ K)$.

Heat Capacity and Entropy

The molecular constants and vibrational frequencies are those calculated by Aleksandrovskaya et al. (2). Later works (3, 4, 5) mistakenly cite this work as observed data.

The principal moments of inertia are: $I_A = I_B = I_C$ = 431.1831 x 10^{-39} g cm^2.

PREVIOUS: December 1973 (1 atm) CURRENT: December 1973 (1 bar)

$S°(298.15\ K) = [258.153 \pm 3.3]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 393.65 \pm 3.0\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -189.54 \pm 16.7\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 19.665 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Schafer and Heine (1) measured the enthalpies of solution of Si(cr) and SiI_4(cr) in an HF solution containing AgF. For the overall reaction $SiI_4(cr) + 4Ag(cr) = Si(cr) + 4\ AgI(cr)$, they reported $\Delta_r H°(298.15\ K) = -13.80 \pm 0.44\ kcal\ mol^{-1}$. Using auxiliary data for AgI (2), we calculate $\Delta_f H°(298.15\ K) = -45.3\ kcal\ mol^{-1}$ for SiI_4(cr). We adopt this value and assign an uncertainty of $\pm 4.0\ kcal\ mol^{-1}$ due to the overall inconsistency in the SiI_4 thermochemical data. Refer to the SiI_4(g) table for more details.

Wolf (3) studied the enthalpies of solution of SiI_4(cr) and Na_2SiO_3(cr) in caustic solution. The net reaction of interest $SiI_4(cr) + 6NaOH(cr) = Na_2SiO_3(cr) + 4NaI(cr) + 3H_2O(\ell)$ yielded a enthalpy of reaction of $\Delta_r H°(298.15\ K) = -191.5 \pm 1.5\ kcal\ mol^{-1}$ based on the appropriate combination of results from five solution studies. Using current auxiliary data (4, 5), we calculate $\Delta_f H°(298.15\ K) = -51.0\ kcal\ mol^{-1}$ for SiI_4(cr). This data is suspect due to uncertainties in how Wolf converted his data from Na_2SiO_3(calorimetric solution) to Na_2SiO_3(cr).

Heat Capacity and Entropy

The adopted heat capacity values are from the study of Kurosawa, et al. (6). The data was obtained from an adiabatic calorimeter of a type used for specific heat measurements and differential thermal analysis. Similar studies on Cr(cr) and Si(cr) would suggest uncertainties of the order of 3% near room temperature and 0-10% at 600-70 K.

There is no low temperature heat capacity data for T<298.15 K. The entropy at 298.15 K is chosen from a consideration of the sublimation and vaporization data. Refer to the SiI_4(g) table for additional information. However, the discrepancies in the various vapor pressure studies are such that a precise estimate of the entropy is not possible.

Fusion Data

Kurosawa et al. (6), using differential thermal analysis (DTA) techniques, determined $\Delta_{fus} H° = 4.7\ kcal\ mol^{-1}$, an average of eight measurements with a standard deviation of $0.08\ kcal\ mol^{-1}$. The same study reported T_{fus} = 120.5°C as determined from the cooling curve. McCarty et al. (7) reported T_{fus} = 123.68±0.06°C for 99.998% (mole) pure SiI_4. Other studies have listed melting points in the range 120-127 C as reported by Kurosawa et al. (6). The sublimation and vaporization studies of Bartsch and Wolf (8) suggest a melting point of 123.5 C and a heat of melting of $4.1 \pm 0.6\ kcal\ mol^{-1}$. Due to the short temperature range of measurement in each condensed phase, precise melting data is not expected. In general, the vapor pressure studies, as discussed in the SiI_4(g) table (5), show poor agreement in the vicinity of T_{fus}.

We adopt T_{fus} = 120.5°C and $\Delta_{fus} H° = 4.7\ kcal\ mol^{-1}$ as derived from Kurosawa et al. (6). We assign respective uncertainties of ±3.0 K and $0.5\ kcal\ mol^{-1}$ due to the variances among the various studies.

Sublimation Data

The enthalpy of sublimation, $\Delta_{sub} H°(298.15\ K)$, is the difference between the $\Delta_f H°(298.15\ K)$ values for SiI_4(g) and SiI_4(cr). Three sublimation studies are summarized in the SiI_4(g) table.

PREVIOUS: CURRENT: June 1976

TETRAIODOSILANE (SiI_4) LIQUID M_r = 535.7035

$S°(298.15\ K)$ = [294.309] J K^{-1} mol^{-1}

T_{fus} = 393.65 ± 3.0 K

$\Delta_f H°(298.15\ K)$ = [-174.603] kJ mol^{-1}

$\Delta_{fus} H°$ = 19.665 ± 2.1 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(SiI_4, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of melting, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(393.65\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Kurosawa et al. (1) measured the heat capacity of SiI_4 from the melting point (unspecified). No data was presented but rather smoothed results were represented by an equation, linear in T. This equation is extrapolated to 700 K and to 298.15 K. $S°(298.15\ K)$ is calculated in a manner analogous to that used for $\Delta_f H°(298.15\ K)$.

Vaporization Data

T_{vap} = ~576 K is calculated as that temperature at which the fugacity is one atmosphere for the process $SiI_4(\ell) = SiI_4(g)$. $\Delta_{vap} H°$ is calculated as the difference between the $\Delta_f H°$ values for the ideal gas and the liquid at T_{vap}. The vaporization studies near T_{vap} are discussed in the $SiI_4(g)$ table; they yielded normal boiling points (p = 760 mm Hg) of 574.7 K (2) and 573.7 K (3). The normal boiling point should be slightly lower than our calculated T_{vap} which corresponds to f = 760 mm Hg.

Enthalpy of Formation

The sublimation, vaporization, and decomposition studies on SiI_4 are summarized in the following table. The vapor pressure data from the sublimation and vaporization studies are corrected for vapor non-ideality by means of the equation $\Delta G°/T = -R\ln p - Bp/T$. The Berthelot equation of state and critical constants Tc = 850 K and Pc = 42.1 atm as suggested by Lapidus et al. (1) are used to calculate B.

Source	Reaction*	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(g, 298.15\ K)$ kcal mol^{-1}
(2)	A	13	343-396	16.23±0.32	18.82±0.28	6.9±0.9	-26.48

(7)	C	eqn	1300-1470	59.44	59.84	0.3	-29.99

Reactions: A) $SiI_4(cr) = SiI_4(g)$ B) $SiI_4(\ell) = SiI_4(g)$ C) $SiI_4(g) = Si(cr) + 2I_2(g)$

The 3rd law results of the sublimation and vaporization studies (reactions A and B) perhaps imply a better agreement among the studies than actually exists. For example, the vaporization studies of Andersen and Belz (4) and Uchimura et al. (5) agree very well near T_{vap} but diverge by up to 33% as T decreases to T_{fus}. The vapor pressure results of Bartsch and Wolf (3) cover a very small temperature range and lie 10-15% lower than those of Andersen and Belz (4) and Krichevskii et al. (2). In addition, the decomposition studies (reaction C) suggest a $\Delta_f H°(g, 298.15\ K)$ value 3.6 kcal mol^{-1} more negative than the vapor pressure studies.

We adopt $\Delta_f H°(g, 298.15\ K) = -26.4$ kcal mol^{-1} based primarily on Andersen and Belz (4) and Krichevskii et al. (2). Anderson and Belz (4) are also given primary weight in our selection of S°(cr, 298.15 K). We assign an uncertainty of ±4 kcal mol^{-1} to include the possibility that the decomposition studies (6, 7) may be correct.

Heat Capacity and Entropy

The adopted vibrational frequencies are from the work of Clark and Rippon (8), who recorded the Raman spectra in the vapor phase (210°C). The spectral data were interpreted in terms of a tetrahedral structure. This structure is consistent with the electron diffraction data of Liston and Sutton (9) which suggested a tetrahedral structure with a Si-I bond distance of 2.43±0.02 Å. We adopt this bond distance. The principal moments of inertia are: $I_A = I_B = I_C = 331.8289 \times 10^{-39}$ g cm^2. Shimanouchi, in a recent compilation of molecular vibrational frequencies (10), suggested somewhat different values (168, 63, 405, 94 cm^{-1}), based on earlier infrared and Raman studies by Delwaulle (11) and Delwaulle and Francois (12). Much literature has been published on the inter-relationships between force constants and vibrational frequencies. Since the majority of this work was published prior to the Clark and Rippon study (8), it will not be further discussed or referenced. The same situation exists for temperature dependent thermochemical tabulations for $SiI_4(g)$.

Enthalpy of Formation

The enthalpy of formation of TiI_4(cr) was measured by Johnson et al. (1), based on the enthalpies of hydrolysis of $TiBr_4$(cr) and TiI_4(cr) in sulfuric acid. These data result in a enthalpy of reaction of -57.88 kcal mol^{-1} for the process TiI_4(cr) + $2Br_2(\ell)$ = $TiBr_4$(cr) + $2I_2$(cr), when recalculated with revised values of $\Delta_f H°(298.15\ K)$ for HBr(aq) and HI(aq) (2). Combination of $\Delta_r H°(298.15\ K)$ with auxiliary JANAF data gives the adopted value of $\Delta_f H°(298.15\ K)$.

Heat Capacity and Entropy

King et al. (3) reported the heat capacity and enthalpy of TiI_4(cr) over the temperature range 51 to 428 K. The value of $S°(298.15\ K)$ is calculated from these data based on $S°(51\ K) = 14.62\ cal\ K^{-1}\ mol^{-1}$. The value of $H°(51\ K)-H°(0\ K)$ is calculated to be 0.356 kcal mol^{-1} from a Debye-Einstein extrapolation of the measured heat capacities.

Transition Data

A first order transition was observed by King et al. (2) at 379 K. They reported the measured value of 2.37 kcal mol^{-1}, noting that this value had an uncertainty of 0.15 kcal mol^{-1} due to hysteresis in the transition.

Fusion Data

The melting temperature and enthalpy of fusion were reported by King et al. (2). The large uncertainty of $\Delta_{fus} H°$ is due to the uncertainty and close proximity of the transition at 379 K.

PREVIOUS: June 1964 CURRENT: December 1968

$S°(298.15\ K) = [311.841]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 428\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [-348.314]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 19.832 \pm 0.63\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(TiI_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(TiI_4, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(428\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

King et al. (1) reported the enthalpy of $TiI_4(\ell)$ above the melting temperature. The heat capacity derived from these data is constant. $S°(TiI_4, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting temperature and enthalpy of fusion were reported by King et al. (1).

Vaporization Data

The boiling temperature, T_{vap}, is taken as the temperature at which the fugacity is 1 bar for the reaction $TiI_4(\ell) = TiI_4(g)$. The enthalpy of vaporization is calculated as the difference between $\Delta_f H°$ of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for $TiI_4(g)$.

Bond Angle: I-Ti-I = [109°28']
Product of the Moments of Inertia: $I_A I_B I_C$ = [4.332573 x 10^{-110}] $g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation of TiI_4(g) is calculated from that of TiI_4(ℓ) and the enthalpy of vaporization of the liquid. Blocher and Campbell (1) reported vapor pressure data for TiI_4(ℓ) over the temperature range 473 to 655 K. 2nd and 3rd law analyses of these data give values for $\Delta_{vap}H°(298.15\ K)$ of 17.2±0.1 and 16.98 kcal mol^{-1}, respectively, the 3rd law drift being -0.4±0.2 cal $K^{-1}\ mol^{-1}$. The adopted value of $\Delta_f H°(298.15\ K)$ is based on the 3rd law enthalpy of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiBr_4$(cr), $TiBr_4$(g) and TiI_4(cr) (2). The tetrahedral model is assumed by analogy with $TiCl_4$(g) and $TiBr_4$(g). The principal moments of inertia are: $I_A = I_B = I_C$ = 351.2222 x 10^{-39} g cm^2.

The vibrational frequencies of TiI_4(g) have been estimated by Ushanova et al. (3). The given estimates are based on their predictions and valence force field calculations.

PREVIOUS: December 1968 (1 atm) CURRENT: December 1968 (1 bar)

ZIRCONIUM IODIDE (ZrI_4) CRYSTAL M_r = 598.8380

$S°(298.15\ K) = [260.270 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 772 \pm 2\ K$
$T_{sub} = 705.6\ K$

$\Delta_f H°(0\ K) = [-487.24 \pm 8.4]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -488.69 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_{fus} H° =$ Unknown
$\Delta_{sub} H°(298.15\ K) = 126.357 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

Turnbull (1) measured the enthalpies of reaction for the dissolution of the zirconium tetrahalides in caustic and in water. The reported enthalpies of reaction and the corresponding reactions may be combined to yield the following:

$$ZrI_4(cr) + 4\ NaCl(aq) = ZrCl_4(cr) + 4\ NaI(aq),\ \Delta_r H°(298.15\ K) = -12.50\ kcal\ mol^{-1}$$
$$ZrI_4(cr) + 4\ Cl^-(aq) = ZrCl_4(cr) + 4\ I^-(aq),\ \Delta_r H°(298.15\ K) = -11.97\ kcal\ mol^{-1}$$

Using auxiliary data (2, 4), we calculate $\Delta_f H°(298.15\ K) = -116.52$ and $-117.05\ kcal\ mol^{-1}$ for $ZrI_4(cr)$ from these two reactions. We adopt a mean of these two values, $\Delta_f H°(298.15\ K) = -116.8\ kcal\ mol^{-1}$, and assign an uncertainty of $\pm 1.5\ kcal\ mol^{-1}$. The value suggested by NBS (3) is 1.7 kcal mol^{-1} more positive.

Baev and Shelton (5) reference an enthalpy of formation value for $ZrI_4(cr)$. The reported $\Delta_f H°(298.15\ K) = -105.9\ kcal\ mol^{-1}$ as supposedly extracted from Karapet'yants and Karapet'yants (6). We tentatively discard this value due to the large number of inconsistencies in the reported tabular results of Baev and Shelton (5).

Heat Capacity and Entropy

There is no heat capacity and enthalpy data reported in the literature for $ZrI_4(cr)$. The adopted heat capacity values are estimated such they they parallel those adopted for $ZrCl_4(cr)$ and $ZrBr_4(cr)$ (2) and are consistent with the sublimation data.

The crystal data compilation of Donnay and Ondik (8) does not list the crystal structure of $ZrI_4(cr)$ but does tabulate both $ZrCl_4$ and $ZrBr_4$ as cubic structures. The literature data related to the crystal structure of ZrI_4 is not definitive. Assuming $ZrI_4(cr)$ also has a cubic structure, the adopted heat capacity values are estimated so as to parallel those for $ZrCl_4$ and $ZrBr_4$. The values below 300 K are calculated in the same manner as for $ZrBr_4(cr)$ (2). The high temperature heat capacities are obtained graphically.

Fusion Data

The melting point was observed by Rahlfs and Fischer (9) to be 772±2 K and by Nisel'son (10) to be 773 K.

Sublimation Data

The sublimation data are treated in the $ZrI_4(g)$ table (2). The sublimation temperature, T_{sub}, is calculated from the Gibbs energy crossover between the crystal and gas. Since T_{sub} is less than T_{fus}, the liquid phase is thermodynamically unstable at one atmosphere pressure.

Enthalpy of Formation

The enthalpy of formation for $ZrI_4(g)$ is calculated from the enthalpies of formation and sublimation at 298.15 K. The adopted value for the heat of sublimation, $\Delta_{sub}H°(298.15\ K) = 30.2 \pm 0.5\ kcal\ mol^{-1}$, is based on the 2nd and 3rd law analyses of the sublimation data of Sale and Shelton (1) and Rahlfs and Fischer (2). Using Knudsen effusion techniques, Sale and Shelton (1) studied effusion in a nickel effusion cell for three different orifice areas. The results were then extrapolated to zero orifice area (refer to last line in the following table). Other sublimation studies have been conducted by Rahlfs and Fischer (2), using a liquid tin tensimeter, and by Gerlach et al. (3), using the oscillating quartz fiber method. It should be noted that the work of Rahlfs and Fischer (2) covered an observed pressure range of 4.0 - 272 mm Hg, which is much wider than range covered by Sale and Shelton (1). The adopted $\Delta_{sub}H°(298.15\ K)$ is based on the mean of the 3rd law results of Sale and Shelton (30.01 kcal mol^{-1}, 1) and Rahlfs and Fischer (30.32 kcal mol^{-1}, 2).

The effusion studies (membrane method) by Baev and Shelton (4) are discarded due to the large number of discrepancies in their tabulated results.

In analyzing the vapor pressures for the three sublimation studies (1, 2, 3), corrections were made for non-ideality by means of the equation $\Delta G°/T = -R\ln p - Bp/T$. The Bertholet equation of state and the critical constants $T_c = 959\ K$ and $p_c = 40.7\ atm$ as determined by Nisel'son and Sokolova (5) are used to calculate B.

Heat Capacity and Entropy

The adopted vibrational frequencies are from the work of Clark et al. (6, 7) who recorded the Raman spectra of ZrI_4 in the vapor phase (380-420°C). These studies indicated that ZrI_4 is a tetrahedral monomer in the vapor phase. Shimanouchi, in his compilation of molecular vibrational frequencies (8), also adopted the values of Clark et al. (6, 7) for $ZrI_4(g)$. Rahlfs and Fischer (2), though vapor density measurements had earlier concluded that ZrI_4 was monomeric in the vapor phase.

An electron diffraction study of $ZrI_4(g)$ at 250-270°C was conducted by Zasorin et al. (9). This study confirmed the tetrahedral structure and determined the Zr-I bond length to be 2.660±0.005 Å. We adopt this value. Other interatomic distances reported in the literature are estimates. The principal moments of inertia are: $I_A = I_B = I_C = 397.6172 \times 10^{-39}\ g\ cm^2$.

Much literature has been published on the inter-relationships between force constants and vibrational frequencies. Since the majority of these are based on estimated frequencies, they will not be further discussed or referenced. The same situation is true for thermodynamic tabulations of $ZrI_4(g)$. One exception is that Clark et al. (6) calculated thermodynamic properties based on their experimental vibrational frequencies. Their tabulation is very similar to ours: the differences in the entropy being 0.04 cal K^{-1} mol^{-1} in the range 100-1000 K.

$S°(298.15\ K) = 64.67\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 336.35\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 2.334\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Low temperature heat capacity measurements have been reported by Roberts (1.5-20 K, 1), Krier, Craig, and Wallace (12-320 K, 2), Dauphinee, Martin, and Preston-Thomas (20-330 K, 3), Simon and Zeidler (15-300 K, 4), and Eastman and Rodebush, (70-290 K, 5). A smooth curve was drawn through a large scale plot of the data, giving the most weight to the first three references. Above 300 K, the heat capacity data were adjusted to join smoothly with the enthalpy measurements of Douglas et al. (6).

Fusion Data

The enthalpy of fusion is from the enthalpy measurements of Douglas et al. (6).

Sublimation Data

See the K(g) and K_2(g) tables for details.

POTASSIUM (K) LIQUID A_r = 39.0983

$S°(298.15\ K) = [71.403]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 336.35\ K$

$\Delta_f H°(298.15\ K) = [2.270]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 2.334\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(K, l, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion and the difference in enthalpy, $H°(336.35\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The liquid heat capacity values are derived from the enthalpy measurements of Douglas et al. (1). The heat capactiy curve was extropolated to 298.15 K and 200 K in a reasonable manner.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Vaporization Data

Potassium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1037 K. The vapor composition at this temperature is 94.5 mole % monatomic and 5.5 mole % diatomic gas. The enthalpy of vaporization of 39.1 grams of liquid potassium to this equilibrium mixture is 18.38 kcal.

Enthalpy of Formation

The enthalpy of formation of potassium gas, $\Delta_f H°(298.15\ K)$ = 89.0 ± 0.4 kJ mol^{-1}, is chosen to be the value recommended by CODATA (1). This value was obtained from 2nd and 3rd law treatments of vapor pressure data. The reported vapor pressures were corrected for the effects of $K_2(g)$, using D_0^0 = 49.01 kJ mol^{-1}. At higher pressures an alternate virial treatment was employed.

As stated by CODATA (1), the selected value is the weighted average of the 3rd law values of $\Delta_{sub}H°(298.15\ K)$ calculated from the following studies:

Source	$\Delta_{sub}H°(298.15\ K)$, kJ mol^{-1}	Source	$\Delta_{sub}H°(298.15\ K)$, kJ mol^{-1}
Haycock and Lamplough (2)	89.31 ± 0.65	Venogradov and Volyak (13)	89.27 ± 0.65
Fiock and Rodenbush (3)	89.41 ± 0.65	Achener (14)	88.97 ± 0.69
Edmondson and Egerton (4)	89.71 ± 0.25	Ahpil'rain et al. (15)	88.94 ± 0.47
Weiler (5)	89.71 ± 0.65	Bowles (16)	88.50 ± 1.35
Mayer (6)	88.58 ± 1.00	Gerasimov et al. (17)	89.43 ± 0.50
Neumann and volker (7)	89.56 ± 0.25	Sphil'rain and Nikanorov (18)	88.70 ± 0.85
Walling (8)	88.59 ± 0.75	Schins et al. (19)	88.94 ± 0.50
Makansi et al. (9)	88.73 ± 0.72	Bonilla (20)	88.75 ± 0.65
Buck and Pauly (10)	89.72 ± 0.35	Roeder and Morawitz (21)	89.59 ± 0.38
Stone et al. (11)	88.81 ± 0.90	Kondrat'ev (22)	88.27 ± 0.55
Rigney et al. (12)	88.90 ± 0.93		

The 2nd law calculations from the above sources led to somewhat more positive values.

Heat Capacity and Entropy

The thermal functions for the five alkali metal monatomic gases are calculated by the same procedure. Oberved and estimated atomic energy levels are included in the partition function calculation, using an ionization potential lowering (IP-kT) technique as the cutoff procedure in the energy level summation (24).

The lowest lying levels for these metals [14904 cm^{-1} (Li), 16956 cm^{-1} (Na), 12985 cm^{-1} (K), 12578 cm^{-1} (Cs)] do not contribute to the thermal functions below ~1000 K; there is only a translational contribution below this temperature. Above this approximate temperature, the thermal functions become increasingly sensitive to the partition function cutoff procedure used, due to the combined effect of the observation of atomic energy levels of high principal quantum number and a low ionization potential. Energy levels have been observed up to n = 42 (Li), 59(Na), 79(K), 77(Rb), and 73(Cs). However, not all predicted levels have been observed for each of these principal quantum numbers. The ionization potentials vary from 43487.29 cm^{-1} for Li to 31406.1 cm^{-1} for Cs. In calculating the thermal functions with the inclusion of missing levels up to the high principal quantum numbers just mentioned, the Gibbs energy functions show significant differences (depending on the cutoff procedure) above 3000 K (24).

The atomic energy levels have been taken from the compilation of Corliss and Sugar (14). Our calculated values for the thermal functions are similar to those recommended by CODATA (1). They do differ for two reasons, however. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, the entropies at 298.15 K for all alkali metal gases differs by ~0.004 J K^{-1} mol^{-1}, presumably due to the use of slightly different values for auxiliary data.

State	ϵ_i cm^{-1}	g_i
$^1S_0$	0	1

Enthalpy of Formation

$\Delta_f H°(K^+, g, 0\ K)$ is calculated from $\Delta_f H°(K, g, 0\ K)$ (1) using the spectroscopic value of IP(K) = 35009.78 ± 0.02 cm^{-1} (418.810 ± 0.000 kJ mol^{-1}) from Corliss and Sugar. The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(K^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(K, g, 0\ K)$ by using IP(K) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for K(g), $K^+(g)$, and $e^-(g)$. $\Delta_f H°(K \rightarrow K^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Corliss and Sugar (2), is incomplete because many theoretically predicted levels have not been oberved. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (6) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state; the first excited state is approximately 162507 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (6).

Enthalpy of Formation

The enthalpy of formation, at 0 K, for $K^-(g)$ is calculated from the adopted electron affinity, EA(K, g) = 0.50147 ± 0.00010 eV (48.384±0.010 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (6), was measured by a tunable laser photodetachment threshold technique (2). Additional discussion on $K^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (1, 6), Rosenstock et al. (3), and Massey (4).

$\Delta_f H°(K^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(K, g, 0\ K)$ by using EA(K, g) with JANAF (5) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $K^-(g)$, K(g), and $e^-(g)$. $\Delta_r H°(K^- \rightarrow K + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Capacity and Entropy

The ground state configuration for $K^-(g)$ is given by Hotop and Lineberger (1, 6) and Rosenstock et al. (3). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

POTASSIUM OXIDE (KO) IDEAL GAS M_r = 55.0977

$S°(298.15\ K) = [238.027 \pm 2.1]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [72.89 \pm 41.8]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [71.13 \pm 41.8]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^2\Pi]$	0	[4]

$\omega_e = [350]\ cm^{-1}$ $\omega_e x_e = [2.2]\ cm^{-1}$ $\sigma = 1$
$B_e = [0.3068]\ cm^{-1}$ $\alpha_e = [0.0027]\ cm^{-1}$ $r_e = [2.2]$ Å

Enthalpy of Formation

Brewer and Margrave (1) suggested that the $\Delta_f H°$ value for MO(g) from the gaseous ions can be taken as the mean of the corresponding $\Delta_f H°$ values for the alkali fluoride and chloride with a maximum uncertainty of 10 kcal mol^{-1}. We obtain the values $\Delta_r H°(0\ K) = -137.94$ and -117.7 kcal mol^{-1} for the reactions $K^+(g) + F^-(g) = KF(g)$ and $K^+(g) + Cl^-(g) = KCl(g)$, respectively. Assuming $\Delta_r H°(0\ K) = -127.83$ kcal mol^{-1} for the reaction $K^+(g) + O^-(g) = KO(g)$, we calculate $\Delta_f H°(KO, g, 298.15\ K) = 19.0$ kcal mol^{-1} with the JANAF auxiliary values for the gaseous ions.

Based on the assumption that $D_0^0(KO) = 1/2[D_0^0(K_2) + D_0^0(O_2)]$, or $\Delta_r H°(0\ K) = 64.9$ kcal mol^{-1} for the reaciton $KO(g) = K(g) + O(g)$, we evaluate $\Delta_f H°(KO, g, 0\ K) = 15.6$ kcal mol^{-1} or $\Delta_f H°(KO, g, 298.15\ K) = 15.2$ kcal mol^{-1}.

According to Somayajulu (2), in a sequence of similar diatomic molecules, $k_e r_e / D_0^0$ = constant, where k_e = force constant and r_e = equilibrium bond distance. Using $r_e = 1.62$ Å, $D_0^0 = 77.9$ kcal mol^{-1} for LiO(g), $r_e = 2.2$ Å and $k_e(KO)/k_e(LiO) = 0.3015$, we calculate $D_0^0 = 55$ kcal mol^{-1} for KO(g), yielding $\Delta_f H°(KO, g, 298.15\ K) = 26.1$ kcal mol^{-1}. The value k_e is derived from the relation $k_e = 4\pi^2\nu^2\mu$ where ν is the vibrational frequency for the diatomic molecule and μ is the reduced mass.

The value of $\Delta_f H°(KO, g, 298.15\ K)$ is tentatively adopted as 17±10 kcal mol^{-1}.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for the OH(g) molecule, which has the same number of valence electrons. The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for LiF(g) and KF(g). The bond distance is estimated from those for HO(g), HF(g) and KF(g). B_e and α_e are derived from r_e, ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3).

POTASSIUM OXIDE, ION (KO^-) IDEAL GAS M_r = 55.09825

$S°(298.15\ K) = [226.308 \pm 1.3]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-130.09 \pm 83.7]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [-138.07 \pm 83.7]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^1\Sigma]$	0	[1]

$\omega_e = [360]\ cm^{-1}$ $\omega_e x_e = [2.3]\ cm^{-1}$ $\sigma = 1$
$B_e = [0.3068]\ cm^{-1}$ $\alpha_e = [0.0027]\ cm^{-1}$ $r_e = [2.2]$ Å

Enthalpy of Formation

Since the electron affinity of KO(g) is unavailable, the value of $\Delta_f H°(KO^-, g, 298.15\ K)$ is estimated. Assuming that the enthalpy change $\Delta_r H°(0\ K)$ of the reaction (1) $KO^-(g) = K(g) + O^-(g)$ is approximately the average of the $\Delta_r H°(0\ K)$ value for the reaction (2) KO(g) = K(g) + O(g) and (3) KF(g) = K(g) + F(g), we obtain $\Delta_r H°(0\ K) = 1/2(63.5 + 117.3) = 90.4\ kcal\ mol^{-1}$ for reaction (1). However, we compare the $\Delta_r H°(0\ K)$ values for the reactions (4) HO(g) = H(g) + O(g), (5) $HO^-(g) = H(g) + O^-(g)$, and (6) HF(g) = H(g) + F(g), and find that $\Delta_r H°(0\ K)$ for reaction (5) is experimentally determined as 109.7 kcal mol^{-1} which is about 8 kcal mol^{-1} more negative than the average of $\Delta_r H°(0\ K)$ values for reactions (4) and (6). Based on this fact we estimated $\Delta_r H°(0\ K) = 80\ kcal\ mol^{-1}$ for reaction (1), yielding $\Delta_f H°(KO^-, g, 298.15\ K) = -33\ kcal\ mol^{-1}$. The value of $\Delta_f H°(KO^-, g, 298.15\ K)$ is tentatively adopted as $-33 \pm 20\ kcal\ mol^{-1}$. The electronic affinity of KO(g) is derived to be 2.2±0.9 eV. The value of EA for HO(g) is determined as 1.8±0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of KF(g) which is isoelectronic with $KO^-(g)$. The values of ω_e, $\omega_e x_e$ and r_e are estimated by comparison with those for KF(g). The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ using the method recommended by Herzberg (1).

$S°(298.15\ K) = 122.499 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$T_{trs1} = 193.5\ K$

$T_{trs2} = 230.9\ K$

$T_{fus} = 782 \pm 20\ K$

$\Delta_f H°(0\ K) = -285.48 \pm 21\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -284.51 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{trs1} H° = 0.302\ kJ\ mol^{-1}$

$\Delta_{trs2} H° = 0.157\ kJ\ mol^{-1}$

$\Delta_{fus} H° =$ Unknown

Enthalpy of Formation

D'Orazio and Wood (1) measured the enthalpy of solution, $\Delta_{sln}H°(25°C) = -13.0 \pm 0.4$ kcal mol^{-1} for $KO_2(cr) + 1/2\ H_2O(\ell)$. $KOH(aq, 12{,}000, H_2O) + 3/4\ O_2(g)$ which leads to $\Delta_f H°(KO_2, cr, 298.15\ K) = -68.09 \pm 0.4$ kcal mol^{-1}, using the following auxiliary data. $\Delta_f H°(KOH{\cdot}aq, 12{,}000\ H_2O, 298.15\ K) = -115.243$ kcal mol^{-1} (2) and $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.315$ kcal mol^{-1} (3). Giles and Margrave (4) also measured the enthalpy of solution as -13.2 ± 0.8 kcal mol^{-1} from which we obtain $\Delta_f H°(KO_2, cr, 298.15\ K) = -67.88 \pm 0.8$ kcal mol^{-1}. Both $\Delta_{sol}H°$ values have been corrected for impurites present in their samples. The value $\Delta_f H°(KO_2, cr, 298.15\ K) = -68.0 \pm 0.5$ kcal mol^{-1} is adopted in the tabulation.

Kazarnovskaya and Kazarnovskii (5) and deForcrand (6) determined the enthalpy of solution in $H_2SO_4(aq)$ and derived the heat of formation of $KO_2(cr)$ as -67.9 kcal mol^{-1} and -66.8 kcal mol^{-1}, respectively. The former is reliable since their sample was well characterized and corrections for the impurities were included in the $\Delta_{sln}H°$ data (5). The latter did not give enough experimental details to check their derivation.

Heat Capacity and Entropy

The low temperature heat capacities in the temperature range from 52-298 K are obtained from Todd's measurements (7). Two peaks at 193.5 K and 230.9 K were found in his heat capacity data. Below 50 K, the heat capacities were extrapolated using a combination of 1 Debye (θ = 139) and 2 Einstein (θ = 260) functions as suggested by Todd. This extrapolation yields the entropy from lattice contribution as 3.278 cal $K^{-1}\ mol^{-1}$ at 50 K. By neutron diffraction, Smith et al. (8) found an antiferromagnetic transition at 7 K which indicates the existence of an unpaired electron in $KO_2(cr)$. We tentatively adopt $S°(50\ K) = 4.656 \pm 1$ cal $K^{-1}\ mol^{-1}$ which includes both lattice (3.278 cal $K^{-1}\ mol^{-1}$) and unpaired electron (R ln 2) contributions. Heat capacities above 298 K are estimated graphically.

The entropy at 298 K is calculated from the $C_p°$ data and is based on an extrapolation of $S°(50\ K) = 4.656$ cal $K^{-1}\ mol^{-1}$.

Transition Data

Todd (7) observed two anomalies in the heat capacity at 193.5 and 230.9 K which are adopted as two phase transitions in the tabulation. The heats of transition are calculated from the total heats of absorption given by Todd between 180 and 208 K for transition 1 and 217-240 K for transition 2 with extrapolated $C_p°$ below 176 K and above 250 K.

Smith et al. (8) confirmed these two transitions in the neutron diffraction measurements. In addition, they found an antiferromagnetic transition at 7.1 ± 0.5 K and an unusually low temperature phase transition at 12 K. Neuman (9) observed a color change at ~75.7 ± 15°C in the warming and cooling curves for $KO_2(cr)$. This color change represents a phase transition which is in good agreement with Todd's observation.

Fusion Data

Firsova et al. (10) studied the thermograms of $KO_2(cr)$ and found the melting point 509 ± 20°C under atmospheric pressure which is adopted in the tabulation. Earlier melting point data were reported as 380°C by Bluemental (11) and 440°C by deForcrand (6).

POTASSIUM (K_2) IDEAL GAS M_r = 78.1966

D_0^0 = 53.48 ± 1.20 kJ mol^{-1} (natural abundance)
$S°(298.15\ K)$ = 249.690 ± 0.042 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 127.11 ± 2.0 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = 123.68 ± 2.0 kJ mol^{-1}

Spectroscopic Data for $^{39}K_2$ (Ground State: $^1\Sigma_g^+$) in cm^{-1}

ω_e = 92.021 $\omega_e x_e$ = 0.2829 $\omega_e y_e$ = -2.055 x 10^{-3}
B_e = 0.056743 α_e = 1.65 x 10^{-4} (a)
D_e = 8.63 x 10^{-8} r_e = 3.9051 Å

(a) $-7.2 \times 10^{-6}\ (v + 1/2)^2 + 1.5 \times 10^{-7}\ (v + 1/2)^3$.

Enthalpy of Formation

Using the adopted value of the dissociation energy for natural abundance $K_2(g)$, D_0^0 = 53.477 kJ mol^{-1} [D_0^0 for $^{39}K_2$ = 53.474 kJ mol^{-1} as determined by (2)], and the recommended $\Delta_f H°(K, g, 0\ K)$ = 90.14 kJ mol^{-1} from NBS (4), we calculate $\Delta_f H°(K_2, g, 0\ K)$ = 126.80 kJ mol^{-1}. Since this value is only 0.31 kJ mol^{-1} smaller than the NBS recommended value of 127.1 kJ mol^{-1}, we adopt the NBS result. Correcting this value to 298.15 K using the current $H°(298.15\ K)-H°(0\ K)$ = 1.0738 kJ mol^{-1} for $K_2(g)$ and the NBS value of $H°(298.15\ K)-H°(0\ K)$ = 7.092 kJ mol^{-1} for K(cr) (4), we obtain $\Delta_f H°(K_2, g, 298.15\ K)$ = 123.68 kJ mol^{-1}.

Heat Capacity and Entropy

The heat capacity and entropy were calculated using a direct summation technique similar to the $Li_2(g)$ species (see $Li_2(g)$ table) using data given above (1,2). Since insufficient spectroscopic data exist for the lower lying excited electronic states, we performed the calculation in the ground state only. Based on the results of Li_2 and Na_2, we expect that the neglect of these excited states results in only ca. 1-2% lower free energy functions near 6000 K. The heat capacity, however, above 2000 K will be seriously deficient. The actual Cp will probably exhibit temperature dependence similar to that calculated for Li_2 and Na_2. Likewise, the actual entropy will be somewhat larger than given here but these effects will not manifest themselves at temperatures less than ca. 3000 K (for $Na_2(g)$ the entropy of the ground state only at 3000 K is only 1.3 J K^{-1} less than that calculated including the excited states). Separate calculations were performed on the isotopic species $^{39}K_2$, $^{41}K_2$, and $^{39}K^{41}K$ and the results combined according to the natural atomic isotopic abundances (3): ^{39}K, 93.258%; ^{41}K, 6.730% (the diatomic species $^{40}K_2$ was neglected due to the small isotopic abundance of .011%). The spectroscopic input data for the calculation of the isotopic species were calculated from the $^{39}K_2(g)$ data using mass reduced scaling. The rotational levels were weighted according to the nuclear spins of the individual atoms (^{39}K, I=3/2; ^{41}K, I=4) as follows: $^{39}K_2$, even J weight = 0.625, odd J weight = 0.375; $^{41}K_2$, even J weight = 0.556, odd J weight = 0.444. The adopted value of $S°(298.15\ K)$ is only 0.15 J K^{-1} mol^{-1} lower than that adopted by NBS (4).

$S°(298.15\ K) = [94.14 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -363.17 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was reported by Rengade (1) based on the measurements of the enthalpy of solution of K(cr) and K_2O(cr) in H_2O. The same value of $\Delta_f H°(298.15\ K)$ was also given by de Forcrand (2).

Heat Capacity and Entropy

Both $C_p°$ and $S°(298.15\ K)$ were estimated by comparison with those of the Na_2O(cr).

Decomposition Data

T_{dcm} = 1154 K(600mmHg) was taken from (3).

POTASSIUM PEROXIDE (K_2O_2) CRYSTAL M_r = 110.1954

$S°(298.15\ K) = [112.968 \pm 6.3]\ J\ K^{-1}\ mol^{-1}$

T_{fus} = 763 K

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [495.80 \pm 4.2]\ kJ\ mol^{-1}$

$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was reported by NBS (1). The value was based on the measured decomposition pressure of $K_2O_2(cr)$ by Centnerzwer and Blumenthal (2).

Heat Capacity and Entropy

The heat capacities and $S°(298.15\ K)$ were estimated by comparison with those for $Na_2O_2(cr)$, $Na_2O(cr)$, and $K_2O(cr)$.

Fusion Data

T_{fus} was reported by Centnerzwer and Blumenthal, (2).

$S°(298.15\ K) = 146.147 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1249\ K$

$\Delta_f H°(0\ K) = -1539.54 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1548.08 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [50.208 \pm 12.6]\ kJ\ mol^{-1}$

Enthalpy of Formation

Hatton et al. (1) conducted enthalpy of solution measurements on K_2SiO_3(cr) and KOH(cr) in HF(aq) at 50°C to determine the enthalpy of formation of the silicate. The results of this work gave a $\Delta_r H°(298.15\ K) = -17.5 \pm 0.5\ kcal\ mol^{-1}$ for the process 2 KOH(cr) + SiO_2(cr, quartz) + K_2SiO_3(cr) + $H_2O(\ell)$. When combined with the auxiliary data for $H_2O(\ell)$ KOH(cr) and SiO_2(cr) (2, 3), we calculate $\Delta_f H°(K_2SiO_3, cr, 298.15\ K) = -369.9 \pm 1\ kcal\ mol^{-1}$.

Urusov (4) summarized the various methods of estimating the enthalpies of formation of silicates using the Born-Haber cycle and energies of atomization. His estimate for $\Delta_f H°(K_2SiO_3, cr, 298.15\ K)$ is $-369\ kcal\ mol^{-1}$.

An earlier estimate by Wilcox and Bromley (5) based upon ionic contributions to crystal lattice energies gave $\Delta_f H°(K_2SiO_3, cr, 298.15\ K) = -367 \pm 15\ kcal\ mol^{-1}$.

An attempt to calculate the $\Delta_f H°(K_2SiO_3, cr, 298.15\ K)$ from HF solution experiments on higher potassium silicates ($K_2Si_2O_5$, $K_2Si_3O_7$) and sodium silicates (6) yielded a value of $-383.8\ kcal\ mol^{-1}$ which is discrepant with the former values.

A value for $\Delta_f H°(K_2SiO_3, cr, 298.15\ K) = -370 \pm 2\ kcal\ mol^{-1}$ has been selected.

Heat Capacity and Entropy

The low temperature heat capacity of K_2SiO_3(cr) has been measured and reported by Stull et al. (7) in the range 15-298 K. They report $S°(298.15\ K) = 34.93\ cal\ K^{-1}\ mol^{-1}$ which is derived from $C_p°$ and an extrapolation of $S°(15\ K) = 0.18\ cal\ K^{-1}\ mol^{-1}$.

Heat capacities above 298.15 K have been estimated by analogy with other alkali metal silicates and borates.

Fusion Data

A melting temperature of 1249 K for K_2SiO_3 was measured by Morey and Bowen (8). The enthalpy of fusion, $\Delta_{fus} H° = 12 \pm 3\ kcal\ mol^{-1}$, was estimated by comparison with other silicates.

POTASSIUM SILICATE (K_2SiO_3) LIQUID M_r = 154.2803

$S°(298.15\ K)$ = [184.256] J K^{-1} mol^{-1} $\Delta_f H°(298.15\ K)$ = [−1499.290] kJ mol^{-1}

T_{fus} = 1249 K $\Delta_{fus}H°$ = [50.208 ± 12.8] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(K_2SiO_3, l, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, H°(1249 K) − H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of $K_2SiO_3(l)$ has been estimated. A constant $C_p°$ of 43 cal K^{-1} mol^{-1} for $K_2SiO_3(l)$ was selected above a hypothetical glass transition temperature of 700 K. Below this temperature the heat capacity was taken as that of the crystal.

$S°(K_2SiO_3, l, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

PREVIOUS: CURRENT: June 1972

$S°(298.15\ K) = 175.544 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha \rightarrow \beta) = 857 \pm 1\ K$

$\Delta_f H°(0\ K) = -1427.20 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1437.71 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{trs} H°(\alpha \rightarrow \beta) = 8.452 \pm 0.418\ kJ\ mol^{-1}$

Enthalpy of Formation

Shibata et al. (1) measured the emf of the cell: K (amalgam, 0.2201%)|K_2SO_4(sat. soln.), Hg_2SO_4|Hg at 298-303 K. From their results at 298 K, correcting the observed voltage for the formation of the K-amalgam, and converting to absolute volts, we have E_{cell} = 3.59172 volts for the reaction at 298 K, 2 K(cr) + Hg_2SO_4(cr) = 2 Hg(ℓ) + K_2SO_4(cr). From this voltage, we calculate $\Delta_r G°(298.15\ K) = -165.656\ kcal\ mol^{-1}$. Taking $\Delta_f G°(Hg_2SO_4, cr, 298.15\ K) = -149.658\ kcal\ mol^{-1}$ (2) and reference entropies from (3), we calculate $\Delta_f G°(K_2SO_4, cr, 298.15\ K) = -315.314\ kcal\ mol^{-1}$ and $\Delta_f H°(K_2SO_4, cr, 298.15\ K) = -343.525 \pm 0.2\ kcal\ mol^{-1}$.

The enthalpy of solution at infinite dilution, $\Delta_{sol} H°(K_2SO_4, cr, 298.15\ K) = 5.677 \pm 0.020\ kcal\ mol^{-1}$, adopted in this tabulation is based on our reanalysis of the enthalpy of solution measurements of Mishchenko and Pronina (4), Tsvetkov and Rabinovich (5), Romanova and Samoilov (6), Cohen and Kooy (7), Bronsted (8), Samilov et al. (9), and Gritsus et al. (10). Enthalpies of dilution are taken from Lange and Streeck (11). When this result is combined with enthalpy of formation of the infinitely dilute ions from CODATA (2), we obtain $\Delta_f H°(K_2SO_4, aq, \infty, 298.15\ K) = -337.940 \pm 0.10\ kcal\ mol^{-1}$ and $\Delta_f H°(K_2SO_4, cr, 298.15\ K) = -343.617 \pm 0.10\ kcal\ mol^{-1}$.

The solubility of K_2SO_4(cr) in water at 298 K has been measured by many workers (4, 12, 14, 15, 16). When the solubility of 0.6919 molal is combined with the activity coefficient data of Stokes (13), we obtain $\Delta_r G°(298.15\ K) = 2423 \pm 20\ cal\ mol^{-1}$ for the reaction $K_2SO_4(cr) = 2\ K^+(aq, \infty) + SO_4^{-2}(aq, \infty)$. When this result is combined with enthalpies of formation and entropies from (3), we obtain $\Delta_f H°(K_2SO_4, cr, 298.15\ K) = -343.595 \pm 0.2\ kcal\ mol^{-1}$.

We adopt the value of $\Delta_f H°(298.15\ K)$ obtained from the enthalpy of solution measurements.

Heat Capacity and Entropy

Low temperature heat capacities of K_2SO_4(cr, α) have been measured by Moore and Kelley (17) from 52.7-295.4 K and by Paukov (18) from 12.5-299.5 K. The heat capacities reported by Moore and Kelley are systematically lower by about 0.5% than those of Paukov. Our adopted value of $S°(298.15\ K) = 41.956 \pm 0.2\ cal\ K^{-1}\ mol^{-1}$ is based on $S°(12.5\ K) = 0.068\ cal\ K^{-1}\ mol^{-1}$ (18) and $H°(12.5\ K) - H°(0\ K) = 0.640\ cal\ K^{-1}\ mol^{-1}$ derived from a Debye T^3-law extrapolation.

Heat capacity data measured by adiabatic calorimetry in the range 298.5-773.7 K have been reportd by Shmidt (19). In addition, drop calorimetric measurements have been reported by the following workers; Shomate and Naylor (20), Dworkin and Bredig (21), Denielou et al. (22), and Rubinchik et al. (23). The heat capacity and enthalpy curves between 298 K and 857 K are obtained by orthogonal polynomial curve-fitting of all the data listed above. These data are in good agreement.

Transition Data

K_2SO_4(cr, α) is the low-temperature form (sometimes denoted as K_2SO_4, II). The mineral is known as arcanite and exists in the form of orthorhombic crystals (space group D_{2h}^{16} -Pnma, 24). The orthorhombic-to-hexagonal transition temperature for K_2SO_4 is selected as 857±1 K from the calorimetric work of Dworkin and Bredig (21) and Rubinchik et al. (23) and the polymorphism study of Pistorius and Rapoport (25). The enthalpy of transition is determined by taking the difference between the adopted enthalpy curves of α- and β-K_2SO_4 extrapolated to 857 K.

PREVIOUS: December 1971 CURRENT: June 1978

$S°(298.15\ K)$ = [192.2±(] J K^{-1} mol^{-1}

$T_{trs}(\alpha + \beta)$ = 857 ± 1 K

$T_{fus}H°(\beta + \ell)$ = 1342 ± 1 K

$\Delta_f H°(298.15\ K)$ = [-1424.243] kJ mol^{-1}

$\Delta_{trs}H°(\alpha + \beta)$ = 8.452 ± 0.418 kJ mol^{-1}

$\Delta_{fus}H°(\beta + \ell)$ = 34.392 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(K_2SO_4, cr, \beta, 298.15\ K)$ is calculated from $\Delta_f H°(K_2SO_4, cr, \alpha, 298.15\ K)$ by adding the enthalpy of transition ($\alpha + \beta$), $\Delta_{trs}H°$, and the difference in enthalpy, H°(857 K)-H°(298.15 K), between the alpha and beta crystalline forms (1).

Heat Capacity and Entropy

High temperature enthalpy measurements by drop calorimetry were carried out by Shomate and Naylor (2, 872.4-1258.8 K), Rubinchik et al. (3, 859.0-1340.7 K) Dworkin and Bredig (4, 868.5-979.9 K), and Denielou et al. (5, 864-1300 K). The data of (2) are systematically higher by about 0.5% than the data from (3, 4, 5). $C_p°$ values are derived from the smoothed curves and *extrapolated* to 298.15 K and 1500 K. $S°(K_2SO_4, \beta, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Transition Data

The high temperature β-modification of K_2SO_4 is of hexagonal structure, space group D^3_{3d}-P3m1 (6). The transition from the low temperature orthorhombic pseudohexagonal modification occurs at 857±1 K (1).

Fusion Data

The adopted melting point of 1342 K was determined by Shomate and Naylor (2) and Rubinchik et al. (3). The heat of fusion, $\Delta_{fus}H°$ = 8.220±0.400 kcal mol^{-1}, is calculated from the difference between the smoothed relative enthalpy of the liquid (see $K_2SO_4(\ell)$ table) and the adopted enthalpy value for the β-crystalline form at T_{fus}.

PREVIOUS: CURRENT: June 1978

$S°(298.15\ K) = [211.505]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}(\beta + \ell) = 1342 \pm 1\ K$

$T_{dcm} = 2567\ K$

$\Delta_f H°(298.15\ K) = [-1393.668]\ kJ\ mol^{-1}$

$\Delta_{fus}H°(\beta + \ell) = 34.392\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(K_2SO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(K_2SO_4, \beta, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, H°(1342 K)-H°(298.15 K), between the β-crystal and liquid (1).

Heat Capacity and Entropy

Enthalpies for $K_2SO_4(\ell)$ have been measured by drop calorimetry by Shomate and Naylor (1358-1698 K, 2), Denielou et al. (1350-1550 K, 3), and Rubinchik et al. (single point at 1344.84 K, 4). A constant heat capacity of 46.15 cal K^{-1} mol^{-1} is selected above a hypothetical glass transition at 800 K. Below the glass transition, the heat capacity is taken as that of the orthorhombic crystal.

$S°(K_2SO_4, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See K_2SO_4(cr, β) table for details.

Vaporization and Decomposition Data

$K_2SO_4(\ell)$ can vaporize to the gaseous monomer $K_2SO_4(g)$ or decompose according to $K_2SO_4(\ell) = 2\ K(g) + SO_2(g) + O_2(g)$. Vaporization pressures from the two processes are of comparable magnitude in the vicinity of the melting point (6). Recent experimental data for vaporization of K_2SO_4(cr) (5, 6) are in good agreement with dissociation pressures and the heat of reaction calculated from the JANAF Thermochemical Tables (1). Molecular vaporization data are discussed on the $K_2SO_4(g)$ table (1). T_{vap} = 2975 K is the calculated temperature at which the Gibbs energy difference is zero for the reaction $K_2SO_4(\ell) = 2\ K(g) + SO_2(g) + O_2(g)$. Decomposition to the oxides of potassium produces significantly lower decomposition pressures than decomposition to the metal. Significant decomposition can occur in the presence of water vapor according to $K_2SO_4(\ell) + H_2O(g) = 2\ KOH(g) + SO_2(g) + 1/2\ O_2(g)$.

Ground State Quantum Weight: [1] $\sigma = 4$

Point Group: D_{2h}

Bond Distances: S-O = 1.47 Å K-O = 1.45 Å

Bond Angles: O-S-O = 109.47° O-K-O = 58.67°

Product of the Moments of Inertia: $I_A I_B I_C = 2.626307 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

The adopted value of the enthalpy of formation is based on JANAF analyses of the vaporization data given below. Earlier data on the vaporizaiton of K_2SO_4 is extremely discordant (for a review, see 10). Dissociation and other reactions play an important role in K_2SO_4 vaporization (see $K_2SO_4(\ell)$ table).

Torsion-effusion studies on the vaporization of $K_2SO_4(g)$ by Lau et al. (3) showed an orifice dependence which was reproduced in four separate runs. Plante et al. (2) did not observe this orifice size dependence in their effusion study, obtaning similar total pressures in two separate experiments. Calculated dissociation pressures were subtracted in both studies to obtain $K_2SO_4(g)$ pressures. Similar results were obtained by Efimova and Gorokhov (1). We have corrected the effusion data of Kosugi (11) for dissociation. The 3rd law enthalpy of sublimation from the three studies (1, 2, 3) are in very good agreement indicating similar $K_2SO_4(g)$ pressures. The studies of Lau et al. (3) and Efimova and Gorokhov (1) yield 2nd law enthalpy of sublimation (from $K_2SO_4(cr, \infty)$) some 6 kcal mol^{-1} greater than our calculated 3rd law enthalpy.

Lau et al. (3) and Efimova and Gorokhov (1) also carried out mass spectrometric measurements of the $K_2SO_4^+$ ion intensity as a function of temperature. The 2nd law enthalpy of sublimation of Lau et al. (3) obtained in two separate mass spectrometric experiments tend to corroborate their 2nd law enthalpy from the torsion-effusion measurements. The 2nd law enthalpy of Efimova and Gorokhov (1) as well as that of Ficalora et al. (12) are more in line with our 3rd law effusion values. Kosugi (11) did not observe the $K_2SO_4^+$ ion in his mass spectrometric experiments. The appearance potential of $K_2SO_4^+$ has been measured as 7.40±0.5 eV (12), 8.40±0.3 eV (3) and 8.0 eV (1).

We have discounted the transpiration experiments of Halstead (13) and Dubois and Millet (14). The calculated 3rd law $\Delta_r H°(298.15\ K)$ may have an uncertainty of 3 kcal mol^{-1} since the JANAF Gibbs energy functions are partially based on the estimated molecular constants of $K_2SO_4(g)$. Our adopted $\Delta_f H°$ is based on a weighted average of the 3rd law results from (1, 2, 3).

*Reactions: A) $K_2SO_r(cr, \beta) = K_2SO_r(g)$ B) $K_2SO_4(\ell) = K_2SO_4(g)$

Heat Capacity and Entropy

The adopted structure (D_{2h} symmetry) is based on the high temperature electron diffraction study of Spiridonov and Lutoshkin (5). This symmetry is supported by the similar work of Ugarov et al. (4) on Cs_2SO_4 and the IR and Raman study of Atkins and Gingerich (7) on K_2SO_4 and Na_2SO_4. The molecule can be pictured as having a central sulfur atom surrounded at the corners of a tetrahedron by four oxygen atoms with bridging potassium atoms between two pairs of oxygens forming two planar mutually perpendicular KO_2S rings. The sulphate core is fairly rigid while the metal atoms undergo large amplitude motions. The internuclear distances of 1.47 Å for S-O and 2.45 Å for K-O are from (5) as are the O-S-O and O-K-O angles. The principal moments of inertia are $I_A = 15.3096 \times 10^{-39}$ and $I_B = I_C = 130.9758 \times 10^{-39}\ g\ cm^2$.

Atkins and Gingerich (7) have observed the infrared and Raman spectra of K_2SO_4 and Na_2SO_4 isolated in oxygen and nitrogen matrices at 12 K. Five of the eleven fundamental frequencies were observed in this work. Good agreement exists between these observations and the frequencies adopted by Gurvich et al. (8). The two other sulphate-ion group fundamentals are taken from the Raman study of Davies and Sandford (9). The low-frequency fundamentals involving the metal atoms are taken from the infrared study of Belyaeva et al. (8). These authors observed the spectra of K_2SO_4, Rb_2SO_4 and Cs_2SO_4 isolated in Ar, Kr, and Xe matrices at 4.2 K. Uncertainties in the location of the gas phase frequencies may contribute 4 cal K^{-1} mol^{-1} to S°(298.15 K).

PREVIOUS: June 1978 (1 atm) CURRENT: June 1978 (1 bar)

$S°(298.15\ K) = 115.06 \pm 16.7\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 1050 \pm 10$ K (diffuse lambda transition)
$T_{fus} = 1221 \pm 10$ K

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -376.56 \pm 12.6\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 16.150 \pm 0.17\ kJ\ mol^{-1}$

Enthalpy of Formation

Experimental measurements leading to the enthalpy of formation of K_2S(cr) are summarized below.

Source	Reaction	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
Sabatier (1)	$\Delta_{sln} H°$ K_2S(cr) and K(cr); $\Delta_n H°$ KOH(aq) + H_2S(aq)	-103.4
Rengade and Costeanu (2)		-87.3
Letoffe et al. (3)	H_2SO_4(aq, 1100 H_2O) + K_2S(cr) = K SO (soln.) + H S(g)	-92.1[a]

a. *The authors' value of -91.1±0.9 kcal mol^{-1} is changed by new $\Delta_f H°(298.15\ K)$ values for H_2SO_4(aq, 1100 H_2O), K_2SO_4(cr) and H_2S(g) (4, 5).*

Since Sabatier himself has expressed reservations because of impure material, we eliminate his value and adopt the average of the other two values, $\Delta_f H°(K_2S, cr, 298.15\ K) = -90 \pm 3$ kcal mol^{-1}.

Heat Capacity and Entropy

The heat capacity is taken from the drop calorimetry of Dworkin and Bredig (384 to 1260 K) (6). Between 298 and 820 K, the observed enthalpy differences and the constraint of passing through zero at 298.15 K are fit by a linear least squares technique; $C_p° = 15.99 + 6.22 \times 10^{-3}\ T$ cal K^{-1} mol^{-1} (298-820 K). The heat capacity in the observed diffuse lambda transition region, 820-1100 K, *was adjusted to properly reproduce the observed enthalpies. The sharp heat capacity maximum occurs at 1050 K (6) and* 46.60 cal K^{-1} mol^{-1}. From 1100 K to the melting point, 1221 K (7), the heat capacity was found to be constant at 34.02 cal K^{-1} mol^{-1}.

Freeman (8) has estimated $S°(K_2S, cr, 298.15\ K) = 27$ cal K^{-1} mol^{-1}; Voronin (9) also has estimated 27 cal K^{-1} mol^{-1}. Kelley's additive entropy constants give 28.0 We adopt $S°(K_2S, cr, 298.15\ K) = 27.5 \pm 4$ cal K^{-1} mol^{-1}.

Transition and Fusion Data

A crystal II to crystal I transition at 419.6 K with a enthalpy change of 0.085 kcal mol^{-1} has been listed (10) from Bridgman (11). However, West (12) found no change in the x-ray powder diffraction pattern over the 298-473 K range. Although not definitive because of the small heat change listed, the drop calorimetric enthalpy measurements of Dworkin and Bredig (6) do not show this transition. Therefore, we do not indicate any solid state transition at 419.6 K.

The diffuse lambda transition has been discussed above.

A melting point of 1221 K was determined by thermal analysis (cooling curves) of the K-K_2S system by Dworkin and Bredig (7). *This is considerably higher than earlier values of 1108 K (13) and 1185 K (14), but it is confirmed by their drop calometric* measurements (6). A melting point of 1221±10 K is adopted with $\Delta_{fus} H° = 3.86 \pm 0.04$ kcal mol^{-1} (6).

POTASSIUM SULFIDE (K_2S) LIQUID M_r = 110.2566

$S°(298.15\ K) = [141.172]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1221 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [-346.506]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 16.150 \pm 0.17\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(K_2S, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, H°(1221 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity was derived from drop calorimetric enthalpy measurements by Dworkin and Bredig (2, 1221-1260 K) and is constant at 24.13 cal K^{-1} mol^{-1} over the range measured. A glass transition temperature is assumed at 820 K with $C_p° = 24.13$ above this temperature and $C_p°$ equal to that of the crystal below this temperature.

$S°(K_2S, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Zero by definition.

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore (1, 9). All predicted levels have been observed for n=4 but above that many predicted levels are missing. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (2) has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels; the first excited level is nearly 80000 cm^{-1} above the ground state. Therefore, we list the ground state only. Extension to higher temperatures may require consideration of excited states and utilization of different fill and cutoff procedures (2).

The thermodynamic functions at 298.15 K agree exactly with recent CODATA recommendations (3) except for two minor differences First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the rare gases arise due to the use of slightly different values for R; this table uses R = 8.31441 J K^{-1} mol^{-1}. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren et al. (4), Hilsenrath et al. (5), Gurvich et al. (8), and Wagman et al. (12). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which in this tabulation are based on the 1981 scale (6) and the 1973 values (7), respectively.

Phase Data

The triple point, 115.770 K, and boiling point, 119.800 K, are secondary fixed points of IPTS-68 (10,11). Hultgren et al. (4) had recommended a triple point of 115.78 K (0.7220 atm) and a boiling point of 119.86 K (1 atm). These values are provided for the convenience of the reader and have not been evaluated by the present authors. As a result of these low values, the reference state for krypton is chosen to be the ideal gas at all temperatures. This may differ from the choice of other authors.

$^2P_{1/2}$	5371.00	2

Enthalpy of Formation

The ionization limit of neutral krypton (112914.5±0.1 cm^{-1}) reported by Moore (1) is adopted as $\Delta_f H°(0\ K)$ for $Kr^+(g)$. The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ mol^{-1}, which is derived from the 1973 CODATA fundamental constants (2). The uncertainty in the ionization limit is estimated to be ± 0.1 cm^{-1} which corresponds to an uncertainty of ±0.012 kJ mol^{-1} in the enthalpy of formation. Rosenstock et al. (9) and Levin and Lias (11) have summarized additional ionization potential and appearance potential data. The recent spectroscopic study by Yoshino et al. (12) is in agreement with our adopted value. Gurvich et al. (8) and Wagman et al. (10) adopted the same ionization potential, but the use of slightly different fundamental constants by Wagman et al. (10) resulted in an enthalpy of formation difference of 0.012 kJ mol^{-1}. However, the study by Chaghtai et al. (13) suggests an ionization potential which is larger by 10 cm^{-1}.

$\Delta_f H°(Kr^+, g, 298.15\ K)$ is obtained from $\Delta_f H°(Kr, g, 0\ K)$ by using IP(Kr) with JANAF (3) enthalpies $H°(0\ K)-H°(298.15\ K)$ for $Kr^+(g)$, Kr(r), and $e^-(r)$. $\Delta_r H°(Kr = Kr^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (9). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights given by Moore (4) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (5) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the $^2P_{1/2}$ level; the next lowest level is over 109000 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the ground state and the $^2P_{1/2}$ state, with the energy of the latter state taken from a more recent study by Moore (1). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (5).

The thermodynamic functions reported here agree with those of Green et al. (6), Hilsenrath et al. (7), and Gurvich et al. (8) except for one or two minor changes. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the cited references used a pressure of 1 atm. Second, smaller differences arise from the use of slightly different values for the fundamental constants, the relative ionic mass, and the position of the $^2P_{1/2}$ electronic level.

Lithium (Li) Li_1(ref)

$S°(298.15\ K) = 29.085\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 453.69\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 3.000 \pm 0.015\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Heat capacities have been reported by the following authors for the temperature ranges indicated: Roberts (1), 1.5 to 20 K (Li 99.5% pure); Simon and Swain (2) 15 to 300 K; Martin (3) 22 to 300 K(Li 99.95% pure); Douglas et al. (4) 289.15 K to 1200 K (Li 99.98% pure). Martin (3) in a series of determinations, found that C_p depended on the thermal history of the sample; a peak at roughly 107 K was ascribed to a martensitic transformation. There is excellent continuty between the results of Roberts (1) and of Martin (3), while those of Martin (3) and Douglas et al. (4) differ by 1% at 300 K and have been smoothly joined. The values of Simon and Swain (2) were not used as they were 5% lower than Martin's (3) and did not show the peak at 107 K; also their values for Al_2O_3, reported at the same time, are lower than recent measurements. Heat capacities between 1200 K and the normal boiling point were obtained from the enthalpy equation given by Douglas et al. (4) between 420° and 900°C.

Fusion Data

Douglas et al. (4) report the triple point to be 180.54°C, which is here adopted as the melting point since the densities of solid and liquid lithium at 180°C are not available for calculating dT_{fus}/dP. The same authors (4) give the enthalpy of melting as 432.3 ± 2.2 J g^{-1}.

Sublimation Data

Lithium vapor contains an appreciable amount of dimer, whose enthalpy of dissociation has been selected by Evans (5), from spectroscopic and molecular beam measuresments to be 25.76 ± 0.10 kcal mol^{-1} at 0 K. This enthalpy of dissociation, together with the thermodynamic functions calculated in this work, has been used to find the partial pressures of Li(g) and Li_2(g) from the measured total vapor pressures. Hartmann and Schneider (6), report values from 1204 to 1353 K; while Mancherat (7) reports effusion measurements from 735 to 915 K. Mancherat's (7) pressures are calculated on the assumption of monatomic vapor and have been recalculated to fine the true total pressure. Effusion measurements by Lewis (8) and Bogros (9) have been disregarded. Mancherat (7) considers them to be inaccurate because of impurities in the lithium used, and Lewis (8) used a doubtful calibration method. Enthalpy of sublimation to monatomic vapor calculated from the vapor pressures of Hartmann and Schneider (6) and of Mancherat (7) agree to within 2% and the average value has been adopted. The enthalpy of sublimation of the dimer was then calculated using this value.

LITHIUM (Li) LIQUID A_r = 6.941

$S°(298.15\ K) = [33.938]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1843\ K$

$\Delta_f H°(298.15\ K) = [2.380]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 3.000 \pm 0.015\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Li, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion and the difference in enthalpy, $H°(453.69\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The liquid heat capacity values are derived from the enthalpy measurements of Douglas et al. (1). The heat capacity curve was extrapolated to 298.15 K and 2000 K in a reasonable manner.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The enthalpy of fusion and the melting point were measured by Douglas et al. (1).

Vaporization Data

Lithium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm at 1620 K; the vapor pressure of the monatomic gas reaches 1 atm at 1638 K and the enthalpy of vaporization to monatomic gas is 35.16 kcal mol^{-1}.

Enthalpy of Formation

The enthalpy of formation of lithium gas is chosen to be the value recommended by CODATA (1). This value was obtained from 2nd and 3rd law treatments of vapor pressure data. The reported vapor pressures were corrected for the effects of $Li_2(g)$, using $D_0{}^0$ = 101.02 kJ mol^{-1}.

As stated by CODATA (2), the selected value is the weighted average of the 3rd law values of $\Delta_{sub}H°(298.15\ K)$ calculated from the following data:

Source	$\Delta_{sub}H°(298.15\ K)$, kJ mol^{-1}
Hartmann and Sckneider (3)	159.04 ± 1.56
Bohdansky and Schins (4)	159.54 ± 1.85
Schins et al. (5)	159.22 ± 1.81
Rigney et al. (6)	159.34 ± 1.85
Anisimov and Volyak (7)	159.60 ± 1.58
Shpilrain and Belova (8)	159.06 ± 1.99

The weighted average is $\Delta_{sub}H°(298.15\ K)$ = 159.3 ± 1.0 kJ mol^{-1}.

The 2nd law values calculated from the above sources lead to more positive values. 3rd law values in reasonable agreement with the selected value were calculated from the data of Bogros (9), Maucherat (10), Achener (11), Wu(12), and Bonilla (13).

Heat Capacity and Entropy

The thermal functions for the five alkali metal monatomic gases are calculated by the same procedure. Oberved and estimated atomic energy levels are included in the partition function calculation, using an ionization potential lowering (IP-kT) technique as the cutoff procedure in the energy level summation (16).

The lowest lying levels for these metals [14904 cm^{-1} (Li), 16956 cm^{-1} (Na), 12985 cm^{-1} (K), 12578 cm^{-1} (Cs)] do not contribute to the thermal functions below ~1000 K; there is only a translational contribution below this temperature. Above this approximate temperature, the thermal functions become increasingly sensitive to the partition function cutoff procedure used, due to the combined effect of the observation of atomic energy levels of high principal quantum number and a low ionization potential. Energy levels have been observed up to n = 42 (Li), 59(Na), 79(K), 77(Rb), and 73(Cs). However, not all predicted levels have been observed for each of these principal quantum numbers. The ionization potentials vary from 43487.29 cm^{-1} for Li to 31406.1 cm^{-1} for Cs. In calculating the thermal functions with the inclusion of missing levels up to the high principal quantum numbers just mentioned, the Gibbs energy functions show significant differences (depending on the cutoff procedure) above 3000 K (16).

The atomic energy levels have been taken from the compilation of Moore (14, 15). Our calculated values for the thermal functions are similar to those recommended by CODATA (1). They do differ for two reasons, however. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, the entropies at 298.15 K for all alkali metal gases differs by ~0.004 J K^{-1} mol^{-1}, presumably due to the use of slightly different values for auxiliary data.

Enthalpy of Formation

$\Delta_f H°(Li^+, g, 0\ K)$ is calculated from $\Delta_f H°(Li, g, 0\ K)$ (1) using the spectroscopic value of IP(Li) = 43487.150 ± 0.005 cm^{-1} (520.222 ± .000 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Li^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Li, g, 0\ K)$ by using IP(Li) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Li(g), $Li^+(g)$, and $e^-(g)$. $\Delta_f H°(Li \rightarrow Li^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state; the first excited state is approximately 476046 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

Enthalpy of Formation

The enthalpy of formation, at 0 K, for $Li^-(g)$ is calculated from the adopted electron affinity, EA(Li, g) = 0.6180 ± 0.0005 eV (59.627 ± 0.048 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (1), was measured by a tunable laser photodetachment threshold technique (2, 3). Additional discussion on $Li^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (1, 4), Rosenstock et al. (5), and Massey (6).

$\Delta_f H°(Li^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Li, g, 0\ K)$ by using EA(Li, g) with JANAF (7) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Li^-(g)$, Li(g), and $e^-(g)$. $\Delta_r H°(Li^- + Li + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Li^-(g)$ is given by Hotop and Lineberger (1, 4) and Rosenstock et al. (5). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

PREVIOUS: CURRENT: December 1983 (1 bar)

$S°(298.15\ K) = [208.245]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 334.7 \pm 167\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 334.7 \pm 167\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^3\Sigma]$	0	[3]

$\omega_e = [700]\ cm^{-1}$ $\omega_e x_e = [7]\ cm^{-1}$ $\sigma = 1$
$B_e = [1.25]\ cm^{-1}$ $\alpha_e = [0.0183]\ cm^{-1}$ $r_e = [1.71]$ Å

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = 80 \pm 40\ kcal\ mol^{-1}$ is calculated from the following estimates:

Method	D_0^0, kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Estimate D_0^0 from geometric means for Li_2 and N_2	76	75
Estimate from D_0^0 for series $N_2(g)$, CN(g), BN(g), and BeN(g)	40 - 100	110 - 50
Estimate from D_0^0 for series HN(g), HO(g), HF(g), LiF(g) and LiO(g)	20 - 60	130 - 90

Margrave and Sthapitanonda (1) report estimated dissociation energies in the range 111-178 kcal mol^{-1} based on approximate ionic binding energies calculated from ionic radii for N^- in the range 0.70 to 1.08 Å.

Heat Capacity and Entropy

The molecular constants, ω_e, r_e and $\omega_e x_e$ are estimated by comparison with those of CN, BN, CO, BO and LiO. The values of α_e and B_e are calculated from the above constants. The ground state configuration is assumed to be $^3\Sigma$ by analogy with NH and OH^+.

LITHIUM OXYNITRIDE (LiON) IDEAL GAS M_r = 36.9471

$S°(298.15\ K) = 245.332\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [181.91 \pm 41.8]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [179.91 \pm 41.8]\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
1350(1)
330(1)
650(1)

Ground State Quantum Weight: [1] $\sigma = 1$
Point Group: C_s
Bond Distances: O-Li = 1.63 ± 0.07 Å O-N = 1.30 ± 0.05 Å
Bond Angle: Li-O-N = 100 ± 10°
Product of the Moments of Inertia: $I_A I_B I_C = 2.65370 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

In order to estimate the $\Delta_f H°(298.15\ K)$ of LiON(g) a comparison with the known $\Delta_f H°(LiOH, g, 298.15\ K) = -59\ kcal\ mol^{-1}$ was made. This was estimated from bond energies using D(Li-O) = 88 kcal mol^{-1}, the average value in $Li_2O(g)$, and D(O-H) = 111 kcal mol^{-1}, the average value in $H_2O(g)$, which yields an estimated $\Delta_f H°(LiOH, g, 298.15\ K) = -49\ kcal\ mol^{-1}$ or a difference of -10 kcal mol^{-1}. Using D(N=O) = 69 kcal mol^{-1} from $NO_2Cl(g)$(equation 1) and D(Li-O) = 88 kcal mol^{-1} from $Li_2O(g)$, the estimated $\Delta_f H°(298.15\ K) = 53\ kcal\ mol^{-1}$ of LiON(g) was obtained (equation 2). Thus adding the -10 kcal mol^{-1} correction from the above comparison a $\Delta_f H°(298.15\ K) = 43\ kcal\ mol^{-1}$ for LiON(g) was obtained.

The justification for using a N=O bond energy is from the 1.7 bond order reported by Andrews and Pimentel (1) and a comparison of bond lengths.

Equations:
1. $NO_2Cl(g) \rightarrow NOCl(g) + O(g)$
2. $LiON(g) \rightarrow Li(g) + O(g) + N(g)$

Heat Capacity and Entropy

The vibration frequencies, bond distances and bond angle were obtained from Andrews and Pimentel (1). The principal moments of inertia are: $I_A = 1.2707 \times 10^{-39}$, $I_B = 3.9785 \times 10^{-39}$ and $I_C = 5.2492 \times 10^{-39}\ g\ cm^2$.

LITHIUM OXIDE (LiO) IDEAL GAS M_r = 22.9404

$S°(298.15\ K)$ = [210.963] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 84.12 ± 20.9 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = 84.10 ± 20.9 kJ mol^{-1}

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^2\Pi]$	0	4

ω_e = 745 cm^{-1} $\omega_e x_e$ = [4.835] cm^{-1} σ = 1
B_e = [1.333] cm^{-1} α_e = [0.01288] cm^{-1} r_e = [1.62] Å

Enthalpy of Formation

White et al. (1) calculated the enthalpy of formation from their mass spectral data by two different methods.

For the first calculation (a) they combined the slope of the log IT vs 1/T curve for LiO^+ with the slopes for Li^+ and Li_2O^+ for the reaction $Li_2O(g) + Li(g) + LiO(g)$. For the second calculation (b) they assumed a cross section σ LiO/σ Li_2O = 1 and from this they calculated a partial pressure for LiO(g) at 1500 K and an equilibrium constant for the reaction $Li_2O(g) + Li(g) + LiO(g)$. They obtained (a) $\Delta_f H°(298.15\ k)$ = 18.3 kcal mol^{-1} and (b) $\Delta_f H°(298.15\ K)$ = 16.3 kcal mol^{-1}, and used the average value from the two methods for the enthalpy of formation of LiO(g). The JANAF enthalpy of formation, 20.1±5 kcal mol^{-1}, was obtained in the same way using their data and the present tables i.e. (a) $\Delta_f H°(298.15\ K)$ = 22.0 kcal mol^{-1} and (b) $\Delta_f H°(298.15\ K)$ = 18.3 kcal mol^{-1}.

Heat Capacity and Entropy

The molecular constants, $\omega_e x_e$, B_e and α_e, were calculated from ω_e and r_e, reported by White et al. (1). The ground state configuration, $^2\Pi$, was estimated by Gordon (2), Buchler and Stauffer (3) and White et al. (1).

$\Delta_f H°(298.15\ K) = [-66.944]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^1\Sigma]$	0	[1]

$\omega_e = [750]\ cm^{-1}$ $\omega_e x_e = [4.5]\ cm^{-1}$ $\sigma = 1$
$B_e = [1.360]\ cm^{-1}$ $\alpha_e = [0.0121]\ cm^{-1}$ $r_e = [1.6]$ Å

Enthalpy of Formation

Data on the electron affinity of LiO(g) are unavailable, therefore the value of $\Delta_f H°(LiO^-, g, 298.15\ K)$ is estimated. We first assume that the enthalpy change $\Delta_r H°(0\ K)$ of the reaction (1) $LiO^-(g) = Li(g) + O^-(g)$ is close to the average of the $\Delta_r H°(0\ K)$ values for the reactions (2) LiO(g) = Li(g) + O(g) and (3) LiF(g) = Li(g) + F(g). The atom F(g) is isoelectronic with $O^-(g)$. In other words, the $\Delta_r H°(0\ K)$ for reaction (1) is approximately 1/2(76.91 + 135.84) = 106.4 kcal mol^{-1}. Then we compare the $\Delta_r H°(0\ K)$ values for the reactions (4) HO(g) = H(g) + O(g), (5) $HO^-(g) = H(g) + O^-(g)$, and (6) HF(g) + H(g) + F(g), and find that $\Delta_r H°(0\ K)$ for reaction (5) is experimentally determined as 109.7 kcal mol^{-1} which is about 8 kcal mol^{-1} more negative than the average of $\Delta_r H°(0\ K)$ values for reactions (4) and (6). Based on this fact we estimate $\Delta_r H°(0\ K)$ = 96.4 kcal mol^{-1} for reaction (1), yielding $\Delta_f H°(LiO^-, g, 298.15\ K)$ = -15.5 kcal mol^{-1}.

Applying the difference in electron affinity between H(g) and Li(g) to OH(g) gives an approximate value, EA = 1.7 eV (39.2 kcal mol^{-1}) for LiO(g). The values of EA for H(g), Li(g) and OH(g) are taken from (1). Based on $\Delta_r H°(0\ K)$ = 39.2 kcal mol^{-1} for the reaction $LiO^-(g) = LiO(g) + e^-(g)$, we derive $\Delta_f H°(298.15\ K)$ = -19.1 kcal mol^{-1} for $LiO^-(g)$, which is in reasonable agreement with the above estimated value.

The value of $\Delta_f H°(298.15\ K)$ for $LiO^-(g)$ is tentatively adopted as -16±15 kcal mol^{-1}. Using this $\Delta_f H°(298.15\ K)$ value, we derive EA = 1.6±0.7 eV for LiO(g). The electron affinity of OH(g) is 1.8±0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of LiF(g) which is isoelectronic with $LiO^-(g)$. The values of ω_e, $\omega_e x_e$ and r_e are estimated by comparison with the observed data for LiF(g). The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ by use of the method suggested by Herzberg (2).

(c) $+5.672 \times 10^{-8} (v + 1/2) - 1.9002 \times 10^{-9} (v + 1/2)^2$.
(d) These values of α_e and D_e were approximated: equations III,118 and III,123, (4).

Enthalpy of Formation

We adopt the $\Delta_f H°(Li_2, g, 298.15\ K)$ of 215.9 kJ mol^{-1} as recommended by NBS (12). The value adopted for $\Delta_f H°(Li_2, g, 0\ K)$ was obtained using the values of $H°(298.15\ K)-H°(0\ K)$ for $Li_2(g)$ and Li(cr), from JANAF and NBS (12), respectively. This results in $\Delta_f H°(Li_2, g, 0\ K)$ = 215.474 kJ mol^{-1}. Note that this adoption of the NBS value results in a minor inconsistency in the value of D_0^0 for the ground state. In the calculation of $C_p°$ and S° described below, we used D_0^0 = 99.846 kJ mol^{-1} (for $^7Li_2$) whereas the above procedure results in D_0^0 = 100.125 kJ mol^{-1} based on $\Delta_f H°(Li, g, 0\ K)$ from NBS (12). This results in uncertainties in the calculated $C_p°$ and S° of less than 0.002 J K^{-1} mol^{-1} at 6000 K.

Heat Capacity and Entropy

The thermal functions were calculated using a direct summation technique. Included in the calculation were the ground state plus the four lowest lying excited electronic states. Of these excited states, only the $^1\Sigma_u^+$ has been observed spectroscopically. All spectroscopic data for $^7Li_2$ used in this calculation are those recommended by Stwalley (1,2). Separate calculations were performed for each of the three isotopic species $^6Li_2$, $^7Li_2$, and $^6Li^7Li$ and the results were combined according to the natural abundances of the atoms, ^7Li: 92.3191%, ^6Li: 7.6809% (3). Calculation of the $^6Li_2$ and $^6Li^7Li$ species were carried out by adjusting the spectroscopic constants for $^7Li_2$ using a standard reduced mass scaling routine. The summation was extended to the dissociation limit of each state, and thus did not include any of the so-called quasi-bound levels above D° that owe their existence to rotational barriers. A detailed study of the effects of the quasi-bound levels on the thermodynamic properties of diatomic molecules has been recently performed by Mies and Julienne (11). According to their approach, the metastable and "free" contribution to the Gibbs energy function for $Li_2(g)$ at 6000 K is only ca. 4 J K^{-1} mol^{-1} (13).

The excited states contribute significantly to the heat capacity above 2000 K but the affect on the Gibbs energy function is considerably less, only 0.5 J K^{-1} mol^{-1} larger than the ground state contribution at 6000 K. The ground state and $^1\Sigma_u^+$ excited state rotational levels were weighted in accordance with the nuclear spin-rotation interaction (4) as follows: even J weight = 0.625, odd J weight = 0.375 for the $^7Li_2$ species; even J weight = 0.667, odd J weight = 0.333 for the $^6Li_2$ species. Note also that although the Dunham coefficients for the ground state are known to higher order than used here (5), the neglect of these data leads to small errors in the computed functions as follows: S°(6000 K) is 0.4 J K^{-1} mol^{-1} larger than the nontruncated ro-vibrational constant calculation (based on a ground state calculation). The rotational levels were extrapolated to high J values according to the method of Khachkuruzov (6) who proposed a simpler form of Wooley's method (7). Splitting of the rotational levels in the $^3\Sigma$ and $^3\Pi$ states due to rotational-electronic coupling was taken into account only insofar as the electronic degeneracy of these states was increased accordingly. The errors invoked by this approximation are much less than the other uncertainties. The adopted value of S°(298.15 K) is only 0.013 J K^{-1} mol^{-1} lower than that adopted by NBS (12).

PREVIOUS: June 1962 (1 atm) CURRENT: December 1983 (1 bar)

$S°(298.15\ K) = 37.890\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1843\ K$

$\Delta_f H°(0\ K) = -592.39 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -598.73 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [58.576]\ kJ\ mol^{-1}$

Enthalpy of Formation

The selected enthalpy of formation was calculated as follows:

	Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	Source
(A)	$Li_2O(cr) + H_2O(\ell) = 2\ LiOH(aq, \infty)$	-31.74 ± 0.08	(1)
(B)	$Li(cr) + 1/2\ O_2(g) = LiOH(aq, \infty)$	-121.572 ± 0.019	(2)
(C)	$H_2(g) + 1/2\ O_2(g) = H_2O(\ell)$	-68.3174	(3)
(D)	$2\ Li(cr) + 1/2\ O_2(g) = Li_2O(cr)$*	-143.1 ± 0.5	

* *Reaction (D) is the sum of -(A) + 2(B) - (C).*

Kolesov et al. (1) measured the enthalpy of the reaction of Li_2O with water at 20° in 5 experiments. The mean $\Delta_r H°$ was -31.41 ± 0.08 kcal mol^{-1}. This was brought to 298.15 K by Kolesov using enthalpy data of Johnston and Bauer (4) for Li_2O, Osborne et al. (5) for H_2O, Gucker and Schminke (6) for $C_p°$ of LiOH(aq) and Rossini et al. (3) for aqueous LiOH. In addition to the above, Beketov (7) and Forcrand (8) have reported experimental enthalpies for Li_2O. Rossini et al. and Johnston and Bauer have reported enthalpies of formation for Li_2O recalculated from older data. *Fasolino (9) reported a* $\Delta_f H°(298.15\ K)$ *of* -141.1 ± 4.2 kcal mol^{-1}. He measured the enthalpy of combustion of Li(cr) in O (g) in a Parr bomb.

Heat Capacity and Entropy

The low temperature $C_p°$ data of Johnston and Bauer (4) from [179 - 298 K] was joined graphically to the high temperature $C_p°$ data of Shomate and Cohen (10, 425 - 1045 K) and Rodigina and Gomelskii (11, 370 - 1125 K). S°(298.15 K) was reported by Johnston and Bauer using S°(16 K) = 0.003 cal K^{-1} mol^{-1} (extrap.).

Fusion Data

The melting point of Li_2O is uncertain. The selected melting point, 1843 K, was measured by van Arkel et al. (12). Brewer and Margrave (13) reported the melting point 1700 K. They also stated that van Kooster and Jaeger (14) had reported 1700 (1973 K) as the melting point. The heat of melting, [14] kcal mol^{-1}, was estimated by Glassner (15).

Sublimation Data

$Li_2O(cr)$ vaporizes to $Li_2O(g)$, $LiO(g)$, $Li_2O_2(g)$ and $O_2(g)$ (16 - 20). The major species (0 - 1700 K) are reported to be $Li_2O(g)$, $Li(g)$, and $O_2(g)$ with lesser amounts of $LiO(g)$ and $Li_2O_2(g)$. Hildenbrand et al. (18), U-2298, have reported about equal amounts of Li_2O^+ and Li^+ (1300 to 1550 K) and about *1/30th of this amount of* LiO^+. *White et al. (17) calculated* $\Delta_{sub}H°$ from their mass spectra data. They made two different calculations: (I) for $Li_2O(cr) + Li_2O(g)$, and (II) for $Li_2O(g) + 2\ LI(g) + 1/2\ O_2(g)$, and found: (a) 102.5 kcal mol^{-1} and (b) 99.0 kcal mol^{-1}. They used a weighted average of (a) and (b) and obtained 101.6 kcal mol^{-1} at 0 K. The selected $\Delta_{sub}H°(298.15\ K)$ of 102.3 ± 3 kcal mol^{-1} was obtained in the same manner using their data and the present JANAF functions, i.e., (a) 104.2 kcal mol^{-1} and (b) 100.3 kcal mol^{-1}. Knudson-effusion data of White et al., corrected for dissociation gave 3rd law heats at 298 K of 101.9 kcal mol^{-1} and a 2nd law *heat of 94 kcal mol*$^{-1}$. *Recalculation of* Hildenbrand's dissociation pressure with JANAF values give Li_2O pressures slightly different than those reported. The recalculated pressures give a 3rd law $\Delta_{sub}H°(298.15\ K)$ of 101.7 kcal mol^{-1} for both cells. The corresponding 2nd law values are 85 and 95.5 kcal mol^{-1} for cell 7 and 8. The 3rd law treatment of both sets of data show relatively large trends of $\Delta_{sub}H°$ with T which are probably too large to be only due to errors in the function.

A sample of $LiAlO_2$ was melted 7 times in argon in an arc-image furnace, Prophet (21). *The sample decomposed on fusion and* successive melting points approached that of Al_2O_3. The residue was found to be 95% Al_2O_3 and 5% $LiAl_5O_8$. The sample and residue were characterized by X-ray diffraction. A reasonable assumption from this is that $\Delta_r F°(2000\ K) = 0$ for $2LiAlO_2(cr) = Al_2O_3(cr) + Li_2O(g)$. From this ΔF, a $\Delta_{sub}H°(298.15\ K)$ for Li_2O of 50 kcal mol^{-1} was calculated. A vapor pressure study of the molecular species over the decomposing $LiAlO_2$ might help resolve the discrepancies in lithium oxide $\Delta_{sub}H°$ values.

PREVIOUS: December 1960 CURRENT: March 1964

LITHIUM OXIDE (Li_2O) LIQUID M_r = 29.8814

$S°(298.15\ K) = [55.083]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1843\ K$

$\Delta_f H°(298.15\ K) = [-553.247]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [58.576]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Li_2O, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Li_2O, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(1843\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity was estimated at 8 cal K^{-1} mol^{-1} from comparisons with similar compounds and from Kopp's rule. $S°(Li_2O, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

The vapor over $Li_2O(cr)$ at 1700 K is composed of $Li_2O(g)$, $Li(g)$, $O_2(g)$, $LiO(g)$, and $Li_2O_2(g)$. Thus a boiling point becomes almost meaningless. The value, T_{vap} = 2836 K, listed above is the temperature at which the fugacity of $Li_2O(g)$ reaches one atm. Brewer (1) estimated a boiling point of 2600 K.

Lithium Oxide (Li_2O) Li_2O_1(cr,l)

LITHIUM OXIDE (Li_2O) IDEAL GAS M_r = 29.8814

$S°(298.15\ K) = 229.108\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -165.84 \pm 10.5\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -166.94 \pm 1.5\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[760](1)
[140](2)
987 (1)

Ground State Quantum Weight: [1] $\sigma = 2$
Point Group: D_{2h}
Bond Distance: Li-O = [1.59] Å
Bond Angle: Li-O-Li = 180°
Rotational Constant: $B_0 = 0.480342\ cm^{-1}$

Enthalpy of Formation

The enthalpy of formation was calculated from the enthalpy of formation of the crystal and the enthalpy of sublimation.

Heat Capacity and Entropy

White et al. (1) made an estimate of the bond distance Li-O = 1.59 Å based on an analysis of their vibrational spectra. They found that Li_2O was a linear molecule. Buchler and Stauffer (2) have shown from electric deflection experiments that Li_2O is very probably linear. They also report from the results of an effusion experiment evidence that the electron diffraction data and Li-O bond distance, 1.82 Å reported by Akishin and Rambidi (3) are for Mo-O in Li_2MoO_4 rather than for Li-O in Li_2O. Buchler and Stauffer (2) estimate an Li-O distance of 1.55 Å. White, et al., (1) have estimated the vibrational frequencies ν_1 = [760] cm^{-1} and ν_2 = [140] cm^{-1} and assigned ν_3 = 987 cm^{-1} from their infrared matrix spectra.

LITHIUM PEROXIDE (Li_2O_2) CRYSTAL M_r = 45.8808

$S°(298.15\ K) = [56.484 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = [632.62 \pm 8.4]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was reported by Forcrand (1), based on the measured enthalpies of the reactions of Li_2O_2(cr) with HCl(aq) and LiOH(aq) with H_2O_2(aq).

Heat Capacity and Entropy

Both $C_p°$ and $S°(298.15\ K)$ were estimated by comparison with those of the Na_2O_2(cr), respectively.

Decomposition Data

T_{dcm} was reported to be about 300°C by Wiederhorn et al. (2). The value adopted, T_{dcm} = 468 K, was reported by (3) obtained from Centnerzwer and Blumenthal (4).

Ground State Quantum Weight: [1] σ = 4
Point Group: [D_{2h}]
Bond Distance: Li-O = [1.90] Å
Bond Angle: O-Li-O = [116]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [5.200811 x 10^{-115}] g^3 cm^6

Enthalpy of Formation

The enthalpy of formation, -58 kcal mol^{-1}, was calculated from an equilibrium constant for the reaction 1/2 O_2(g) + Li_2O(g) → Li_2O_2(g) and the current JANAF functions. The equilibrium constant, 0.39, was estimated by White et al. (1), from their mass spectrometric data.

Heat Capacity and Entropy

White, et al., (1) from their spectral data have assigned two observed frequencies and estimated the remaining frequencies using the ionic model calculations of Berkowitz (2) as a guide. They proposed a planar rhombic structure of D_{2h} symmetry, similar to the alkali halide dimers, for the previously undetected Li_2O_2 molecule, and estimated the angle, 116°, and bond distance, 1.90 Å, from their matrix spectra. The principal moments calculated from these molecular constants are: I_A = 2.3369 x 10^{-39}, I_B = 13.7955 x 10^{-39}, and I_C = 16.1324 x 10^{-39} g cm^2.

PREVIOUS: March 1964 (1 atm) CURRENT: March 1964 (1 bar)

$S°(298.15\ K) = 80.295 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1474 \pm 1\ K$

$\Delta_f H°(0\ K) = -1638.57 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1649.50 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 28.033 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpies of solution of LiCl(cr), Li_2SO_4(cr), SiO_2(quartz) and Li_2SO_3(cr) in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (1). The authors derived two values of $\Delta_{sln}H°$ of Li_2O(cr) from those of LiCl(cr) and Li_2SO_4(cr), presumably employing auxiliary data from (2). We recalculate $\Delta_{sln}H°$ of Li_2O(cr) as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal mol^{-1} (sulfate scheme, originally -60.86), using recent $\Delta_f H°(298.15\ K)$ values for LiCl(cr), Li_2SO_4(cr), HCl(aq), H_2SO_4(aq) and Li_2O(cr). The corresponding enthalpy changes, $\Delta_r H°(298.15\ K)$, for the reaction $Li_2O(cr) + SiO_2(quartz) = Li_2SiO_3(cr)$ are derived as -33.08 and -34.17 kcal mol^{-1}. Adopting the weighted average $\Delta_r H°(298.15\ K) = -33.44$ kcal mol^{-1} with $\Delta_f H°(Li_2O, cr, 298.15\ K) = -143.1$ kcal mol^{-1} and $\Delta_f H°(SiO_2, quartz, 298.15\ K) = -217.7$ kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K) = -394.24$ kcal mol^{-1} for Li_2SiO_3(cr). This $\Delta_f H°(Li_2SiO_3, cr, 298.15\ K)$ value is independent of future changes in $\Delta_f H°(298.15\ K)$ of Li_2O(cr) but the values of $\Delta_{sln}H°$ and $\Delta_r H°$ are not independent.

The enthalpies of solution of LiOH(cr) and Li_2SiO_3(cr) in 20 percent HF(aq) at 50°C were measured by Hatton et al. (2). The Li_2SiO_3 sample was prepared from lithium carbonate and silica by fusion under vacuum at 1500 K. Analysis gave 66.74 percent SiO_2 and 15.12 percent Li. The corresponding calculated values are 66.79 and 15.43. Also present were 0.5 percent K and 0.06 percent Na. Corrections were made for impurities in the enthalpy of formation measurements. The results are given as follows:

	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}
2 LiOH(cr, 25°C) + 2 HF(sol, 50°C) + 2 LiF(sol, 50°C) + 2 H_2O(sol, 50°C)	-38.728
SiO_2(cr, 25°C) + 6 HF(sol, 50°C) + H_2SiF_6(sol, 50°C) + 2 H_2O(sol, 50°C)	-32.810
3 H_2O(sol, 50°C) + 2 LiF(sol, 50°C) + H_2SiF_6(sol, 50°C) + Li_2SiO_3(cr, 25°C) + 8 HF(sol, 50°C)	+58.850
H_2O(sol, 50°C) + H_2O(ℓ, 25°C)	-0.450
2 LiOH(cr, 25°C) + SiO_2(cr, 25°C) + Li_2SO_3(cr, 25°C) + H_2O(ℓ, 25°C)	-13.14±0.70

The $\Delta_r H°(298.15\ K)$ for the second reaction was determined by Torgeon and Sahama (4). Based on the calculated enthalpy change for the overall reaction, $\Delta_r H°(298.15\ K) = -13.14$ kcal mol^{-1} and $\Delta_f H°(298.15\ K) = -115.84$, -217.7 and -68.33 kcal mol^{-1} for LiOH(cr), SiO_2(low quartz), and H_2O(ℓ), respectively, we derived $\Delta_f H°(Li_2SO_3, cr, 298.15\ K) = -394.21 \pm 1.0$ kcal mol^{-1}, which is in agreement with the adopted value.

Kroger and Fingas (5) measured the equilibrium pressure of CO_2 over a mixture of Li_2CO_3(cr), SiO_2(quartz) and Li_2SiO_3(cr) from 585 to 781 K. The enthalpy change $\Delta_r H°(298.15\ K)$ of the reaction $Li_2CO_3(cr) + SiO_2(cr) = Li_2SiO_3(cr) + CO_2(g)$ is evaluated by the second and third law methods to be 30.94 and 29.47 kcal mol^{-1}, respectively. Using $\Delta_f H°(298.15\ K) = -290.64$, -217.7 and -94.05 kcal mol^{-1} for Li_2CO_3(cr), SiO_2(cr), and CO_2(g), respectively, and 3rd law $\Delta_r H°(298.15\ K)$, we obtain $\Delta_f H°(Li_2SiO_3, cr, 298.15\ K) = -384.82 \pm 5$ kcal mol^{-1}, which is not used.

Heat Capacity and Entropy

The low temperature heat capacities, 25 - 340 K, were measured by Hatton et al. (3) with an adiabatic vacuum calorimeter, using a nickel-plated copper sample container. During the filling and sealing of the calorimeter, the compound was handled in an anhydrous, CO_2-free atmosphere so as to avoid contamination. The purity of the sample is not well established. The high temperature heat capacities are estimated by summation of the $C_p°$'s of the constituent oxides, Li_2O and SiO_2, and a subsequent correction based upon a comparison of the heat capacities of Na_2SiO_3(cr) and its constituent oxides. These estimated $C_p°$ values are plotted and the resulting curve is joined smoothly with the low temperature $C_p°$ curve at 298 K. The entropy, S°(298.15 K), is derived using the measured low temperature heat capacities, based on $S°(25\ K) = 0.023$ cal K^{-1} mol^{-1}.

Fusion Data

See the liquid table for details.

PREVIOUS: March 1964 CURRENT: June 1967

$S°(298.15\ K)$ = [96.064] J K^{-1} mol^{-1}

T_{fus} = 1474 ± 1 K

$\Delta_f H°(298.15\ K)$ = [-1625.231] kJ mol^{-1}

$\Delta_{fus}H°$ = 28.033 ± 2.1 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Li_2SiO_3, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Li_2SiO_3, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, H°(1474 K)-H°(298.15 K), between the crystal and liquid.

Tschernobaeff (1) measured the enthalpy of reaction between SiO_2 and Li_2CO_3 in a bomb calorimeter, using carbon as the auxiliary combustible material. Based on the derived $\Delta_r H°(298.15\ K)$ = 24.99 kcal mol^{-1} for the reaction $Li_2CO_3(cr) + SiO_2(cr) + Li_2SiO_3(g) + CO_2(g)$, the enthalpy of formation for $Li_2SiO_3(g)$ is evaluated as -389.30 kcal mol^{-1}, which is in fair agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $Na_2SiO_3(\ell)$, $Na_2O(\ell)$ and $Li_2O(\ell)$. A glass transition is assumed at 1000 K; i.e., the heat capacities below 1000 K are taken to be the same as those for $Li_2SiO_3(cr)$.

$S°(Li_2SiO_3, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point has been reported as 1474±1 and 1461 K by Fracek (2) and Van Klooster (3), respectively. The value reported by Kracek is adopted.

Schwartz and Sturm (4) used a cooling-curve method to compare the heats of fusion of $Li_2SiO_3(cr)$ and NaCl(cr). From the reported ratio, $\varepsilon(Li_2SiO_3)/\varepsilon(NaCl)$ = 0.261/0.402, where ε = heat of fusion in kcal g^{-1} and heat of fusion of NaCl(cr), the value $\Delta_{fus}H°$ = 6.7 kcal mol^{-1} is derived.

LITHIUM TITANIUM OXIDE (Li_2TiO_3) CRYSTAL (ALPHA-BETA) M_r = 109.7602

$S°(298.15\ K) = 91.755 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

T_{trs} = 1485 K

T_{fus} = 1820 K

$\Delta_f H°(0\ K) = -1660.065\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1670.671\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 11.506\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 110.165\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was calculated from measurements of solution calorimetry by Todd and Kelley (1) according to the following equation:

$$TiO_2(cr) + Li_2SO_4(cr) + 13.312\ H_2O(\ell) = Li_2TiO_3(cr) + H_2SO_4(aq,\ 12.312\ H_2O) \qquad \Delta_r H°(298.15\ K) = 27.04\ kcal\ mol^{-1}$$

$\Delta_f H°(TiO_2,\ cr,\ 298.15\ K)$ value for rutile was obtained from the JANAF tables and the other $\Delta_f H(298.15\ K)$ values were obtained from (2).

Heat Capacity and Entropy

The low temperature heat capacities were taken from King (3). These low temperature heat capacities were fit to the high temperature enthalpies from Christensen et al. (4).

$S°(298.15\ K) = 21.9\ cal\ K^{-1}\ mol^{-1}$ was obtained from King (3) based on the measured heat capacities and the extrapolated $S°(51\ K)$ value.

Transition Data

Christensen et al. (4) reported that lithium metatitanate undergoes a transition from the α to the β form at 1,485 K with an absorption of 2.750 kcal mol^{-1}.

Fusion Data

The T_{fus} and $\Delta_{fus} H°$ were obtained from Christensen et al. (4).

PREVIOUS: June 1961 CURRENT: March 1964

$S°(298.15\ K) = [147.656]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1820\ K$

$\Delta_f H°(298.15\ K) = [-1566.760]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 110.165\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Li_2TiO_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1820\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacities were reported by Christensen et al. (1). The measured heat capacity is extrapolated to an assumed glass transition temperature of 1214 K, below which the heat capacity is taken to be equal to that of the crystal.

$S°(Li_2TiO_3, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The T_{fus} and $\Delta_{fus}H°$ were obtained from Christensen et al. (1).

$S°(298.15\ K) = 113.947 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha + \beta) = 848 \pm 1\ K$

$\Delta_f H°(0\ K) = -1423.980 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1436.367 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{trs} H°(\alpha + \beta) = 28.451 \pm 1.7\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of solution of Li_2SO_4(*cr*, α) *has been measured* by Ueda (1), Thomsen (2), Pickering (3), Romanova and Samoilov (4) and Tsvetkov and Rabinovich (5). Adopting the results from (1, 4, 5) we have $\Delta_{sln}H°(298.15\ K) = -7.300 \pm 0.1$ kcal mol^{-1} for the enthalpy of solution at infinite dilution. We have used data from Thompson et al. (6) to correct the enthalpy of solution data to infinite dilution. When this result is combined with enthalpies of formation of the infinitely dilute ions from CODATA (7) we obtain $\Delta_f H°(Li_2SO_4, aq, \infty, 298.15\ K) = -350.504 \pm 0.2$ kcal mol^{-1} and $\Delta_f H°(Li_2SO_4, cr, 298.15\ K) = -343.20 \pm 0.3$ kcal mol^{-1}.

Lithium sulfate was studied by hydrochloric acid solution calorimetry by Barany and Adami (8) who obtained $\Delta_r H°(298.15\ K) = -16.020 \pm 0.120$ kcal mol^{-1} for the reaction 2 LiCl(cr) + $H_2SO_4 \cdot 7.068\ H_2O(\ell)$ + 18.394 $H_2O(\ell)$ = Li_2SO_4(cr) + 2 HCL·12.731 $H_2O(\ell)$. When this result is combined with auxiliary data from (9, 10), we obtain $\Delta_f H°(Li_2SO_4, cr, 298.15\ K) = -343.30 \pm 0$ kcal mol^{-1}. Auxiliary data used in the analysis are (in kcal mol^{-1}): $\Delta_f H°(H_2SO_4 \cdot 7.068\ H_2O, 298.15\ K) = -209.566 \pm 0.10$ and $\Delta_f H°(HCl \cdot 12.731\ H_2O, 298.15\ K) = -38.792 \pm 0.010$.

Ueda (1) *measured the emf of the cell:* Li (*amalgam*, 0.035%)|$Li_2SO_4 \cdot H_2O$ (sat. soln.), Hg_2SO_4|Hg at 298 K as E_{cell} = 2.67489 volts. Kelley (17) used this value along with other data to determine $\Delta_f H°(298.15\ K)$ for Li_2SO_4(cr). Adopting results given in Kelley (17), we calculate $\Delta_r G°(298.15\ K) = -165.780$ kcal mol^{-1} for the reaction 2 Li(cr) + Hg_2SO_4(cr) = 2 Hg(ℓ) + Li_2SO_4(cr). Taking $\Delta_f G°(Hg_2SO_4, cr, 298.15\ K) = -149.658$ kcal mol^{-1} (7) and reference entropies from (7), we calculate $\Delta_f G°(Li_2SO_4, cr, 298.15\ K) = -315.438$ and $\Delta_f H°(Li_2SO_4, cr, 298.15\ K) = -343.0 \pm 0.5$ kcal mol^{-1}.

We adopt a value for the enthalpy of reaction based on the solution work of Barany and Adami (8).

Heat Capacity and Entropy

Low temperature heat capacities of Li_2SO_4(cr, α) have been measured by Paukov (11) in an adiabatic calorimeter from 12.00 - 311.11 K. We have smoothed the experimental $C°_p$ data by fitting to orthogonal polynomials over selected temperature intervals. Our adopted value of $S°(298.15\ K) = 27.234 \pm 0.10$ kcal mol^{-1} is based on $S°(14\ K) = 0.051$ kcal mol^{-1} and $H°(14;0) = 0.540$ cal K^{-1} mol^{-1} derived from a Debye T^3-law extrapolation.

Heat capacity data measured by adiabatic calorimetry have been reported by Shmidt (12, 298.5 - 774.3) and by Sjoblom (13, 430 - 845 K). *In addition, drop calorimetric enthalpy measurements have been performed* by Denielou et al. (14, 400 - 848 K), by Clark (15, 488.0 - 848.7 K) and by Voskresenskaya and Banashek (16, 360 - 859 K). The data of Clark is systematically low by 15% while the data from Sjoblom is too high by 10%. There is good agreement among the other three studies (12, 14, 16). We adopt heat capacities above 300 K based on a smooth fit to the combined data from (11, 12, 14, and 16).

Transition Data

Li_2SO_4(cr, α) is the low-temperature form of lithium sulfate (sometimes denoted Li_2SO_4 II). The crystals are monoclinic (space group C_{2h}, $P2_1/c$). The transformation to the high-temperature β-phase (cubic form) occurs at 848±1 K (14, 15). The enthalpy of transition is determined by taking the difference between the adopted enthalpy curves of α- and β-Li_2SO_4 extrapolated to 848 K (see the discussion on the Li_2SO_4(cr, β) table, 18).

$S°(298.15\ K) = [113.802]\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha + \beta) = 848 \pm 1\ K$

$T_{fus}(\beta + \ell) = 1132 \pm 1\ K$

$\Delta_f H°(298.15\ K) = [-1425.373]\ kJ\ mol^{-1}$

$\Delta_{trs}H°(\alpha + \beta) = 28.451 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{fus}H°(\beta + \ell) = 8.577 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Li_2SO_4, cr, \beta, 298.15\ K)$ is calculated from $\Delta_f H°(Li_2SO_4, cr, \alpha, 298.15\ K)$ by adding the enthalpy of transition ($\alpha + \beta$), $\Delta_{trs}H°$, and the difference in enthalpy, H°(848 K)-H°(298.15 K), between the alpha and beta crystalline forms (1).

Heat Capacity and Entropy

High temperature enthalpy measurements by drop calorimetry were carried out by Denielou et al. (2, 860-1110 K), by Clark (3, 874-1103 K), and by Voskresenskaya and Banashek (4, 859-1133 K). In addition, heat capacities have been measured in an adiabatic calorimeter by Sjoblom (5, 873-1073 K). All of the data indicate that $C_p°$ is nearly constant over the temperature interval 848-1132 K. The data of Clark (3) is systematically low by 15% while the other studies (2, 4, 5) are in substantial agreement. We have adopted enthalpies from Denielou et al. (2) for our curve fits, but have neglected points near T_{trs} and T_{fus} where the data shows pronounced curvature. This leads to a constant heat capacity of 51.0 cal K^{-1} mol^{-1} over the range 909-1119 K. Our adopted enthalpies are 1.5% higher than those from Denielou et al. (2) at 848 K and 0.5% higher at 1132 K. We have extrapolated a constant heat capacity below T_{trs} to 700 K at which point we slowly bend $C_p°$ until it is only 5% higher than $C_p°$ for the α-form at 298.15 K. We also extrapolate a constant heat capacity above T_{fus}.

Transition Data

The high temperature β-modification of lithium sulfate (sometimes denoted Li_2SO_4 I) is of cubic structure, space group T_d^2 (6). The α-β transition at 848 K is somewhat gradual and shows a second order rather than first order behavior. We have treated the transition as a first order transition, taking some of the curvature in the enthalpy data (see above) and lumping it into the heat of transition. Reasonable $C_p°$ curves are obtained by omitting from the curve fits those enthalpy data in the vicinity of T_{trs}. T_{trs} = 848 K is selected as the peak of the transition. $\Delta_{trs}H°$ is calculated as the difference in the enthalpy curve fits at T_{trs}.

Fusion Data

The adopted melting point, T_{fus} = 1132±1 K, was determined from the work of Denielou et al. (2, 1130±3 K), Voskresenskaya and Banashek (4), 1133±1 K), and Rea (7, 1132 K). The heat of fusion, $\Delta_{fus}H°$ = 2.050±0.2 kcal mol^{-1}, is calculated from the difference between the smoothed relative enthalpy of the liquid and the adopted enthalpy value for the β-crystalline form at T_{fus}.

LITHIUM SULFATE (Li_2SO_4) LIQUID M_r = 109.9396

$S°(298.15\ K) = [154.332]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}(\beta + \ell) = 1132 \pm 1\ K$

$\Delta_f H°(298.15\ K) = [-1399.296]\ kJ\ mol^{-1}$

$\Delta_f H°(\beta + \ell) = 8.577 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Li_2SO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Li_2SO_4, \beta, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1132\ K) - H°(298.15\ K)$, between the β crystal and liquid.

Heat Capacity and Entropy

Enthalpies for $Li_2SO_4(\ell)$ have been measured by Clark (2, 1145-1179 K), by Voskresenskaya and Banashek (3, 1133-1270 K), and by Denielou et al. (4, 1138-1530 K). The data of Clark is systematically low by 15% while the other two studies (3, 4) are in substantial agreement. We adopt enthalpies based on the work of Denielou et al. (4). We adopt a constant heat capacity of 49.00 cal K^{-1} mol^{-1} at temperatures above a hypothetical glass transition at 680 K. Below the glass transition, the heat capacity is taken as that of the alpha phase. $S°(298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the β-crystal table for details.

Vaporization and Decomposition Data

$Li_2SO_4(\ell)$ can vaporize to the gaseous monomer, $Li_2SO_4(g)$, or decompose according to $Li_2SO_4(\ell) = Li_2O(cr) + SO_2(g) + 1/2\ O_2(g)$ or according to $Li_2SO_4(\ell) = 2\ Li(g) + SO_2(g) + O_2(g)$. Ficalora et al. (5) did not observe ions from Li_2O or Li_2SO_4 in their effusion mass-spectrometric experiments, indicating decomposition occurs to the metal. They determined $\Delta_{dcm}H°(1080\ K) = 324 \pm 12$ kcal mol^{-1}. This is in substantial agreement with JANAF thermodynamic data (1) which indicates $\Delta_{dcm}H°(1080\ K) = 332.3$ kcal mol^{-1}. Effusion and transpiration results of Jagannathan and Wyatt (6) also indicate that decomposition to the oxide is less important then decomposition to the metal. T_{dcm} = ~2466 K is the temperature at which the Gibbs energy change is zero for the reaction $Li_2SO_4(\ell) = Li_2O(\ell) + SO_2(g) + 1/2\ O_2(g)$ and T_{dcm} = 2800 K for the reaction $Li_2SO_4(\ell) = 2\ Li(g) + SO_2(g) + O_2(g)$.

Ground State Quantum Weight: [1] σ = [4]

Point Group: [D_{2d}]

Bond Distances: S-O = [1.48] Å Li-O = [1.90] Å

Bond Angles: O-S-O = [109.47°] O-Li-O = [79.0°]

Product of the Moments of Inertia: $I_A I_B I_C$ = [1.210866 x 10^{-113}] $g^3\ cm^6$

Enthalpy of Formation

Vaporization experiments on Li_2SO_4 have been carried out by Ficalora et al. (1), by Vasilev and Dmitrievskaya (2, 973-1223 K), and by Jagannathan and Wyatt (3, 1227-1371 K). Ficalora et al. (1) did not observe the $Li_2SO_4^+$ ion nor ions from Li_2O in their Knudsen effusion mass-spectrometric experiments. Decomposition to Li(g) was the dominant process observed. Vasilev and Dmitrievskaya (2) carried out Langmuir method experiments on solid and liquid lithium sulfate. Their experimental pressures are less than JANAF calculated dissociation pressures from the two reactions $Li_2SO_4(\ell) = Li_2O(cr) + SO_2(g) + 1/2\ O_2(g)$ and $Li_2SO_4(\ell) = 2\ Li(g) + SO_2(g) + O_2(g)$. We have discounted their results.

Jagannathan and Wyatt (3) carried out Knudsen effusion weight-loss experiments and transpiration experiments (in N_2) on molten lithium sulfate. Their transpiration experiments identified high lithium concentrations in the vapor, so that $Li_2O(cr)$ formation cannot be the major reaction. The effusion experiments yield apparent $Li_2SO_4(g)$ pressures of the same order of magnitude as our calculated decomposition pressures (to $Li_2O(cr)$. The data from (3) leads to $\Delta_r H°(1300\ K)$ = 58±20 kcal mol^{-1} for molecular vaporization. When this result is combined with auxiliary JANAF data (7), we obtain $\Delta_f H°(Li_2SO_4, g, 298.15\ K)$ = -266±20 kcal mol^{-1}.

From trends in the enthalpies and entropies of sublimation for the other alkali sulfates (4), we would estimate $\Delta_r H°(1200\ K)$ = 75±15 kcal mol^{-1} and $\Delta_r S°(1200\ K)$ = 35±5 cal $K^{-1}\ mol^{-1}$ for $Li_2SO_4(\ell) = Li_2SO_4(g)$. This estimate leads to $\Delta_f H°(Li_2SO_4, g, 298.15\ K)$ = -249±28 kcal mol^{-1}. We adopt this estimate for this tabulation.

Heat Capacity and Entropy

The adopted structure (D_{2d} symmetry) is based on the similar symmetry assigned to $Cs_2SO_4(g)$ and $K_2SO_4(g)$ in the high-temperature electron diffraction studies of Ugarov et al. (5) and Spiridonov and Lutoshkin (6). The internuclear distance of 1.48 Å for S-O is taken from data on other sulfates (7) while Li-O = 1.90 Å is an estimate based on trends among lithium and sodium compounds. The Li-O distance of 1.96 Å found by Alcock et al. (8) seems a bit long. The principal moments of inertia are: I_A = 15.5185 x 10^{-39} g cm^2 and $I_B = I_C$ = 27.9333 x 10^{-39} g cm^2.

Estimates of the eleven fundamental frequencies of Li_2SO_4 are based on comparisons with $Na_2SO_4(g)$ and $K_2SO_4(g)$ (7), data on crystalline Li_2SO_4 (9), and on a normal coordinate analysis of Devlin (10). Uncertainties in the estimates of the molecular constants and gas-phase frequencies may contribute 10 cal $K^{-1}\ mol^{-1}$ to S°(298.15 K).

PREVIOUS: December 1978 (1 atm) CURRENT: December 1978 (1 bar)

$S°(298.15\ K)$ = [125.520] J K^{-1} mol^{-1}
T_{trs} = 1209 K
T_{fus} = 1307 ± 1 K

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K)$ = -2560.90 ± 4.2 kJ mol^{-1}
$\Delta_{trs} H°$ = 0.941 kJ mol^{-1}
$\Delta_{fus} H°$ = [53.806] kJ mol^{-1}

Enthalpy of Formation

The enthalpies of solution of LiCl(cr), Li_2SO_4(cr), SiO_2(quartz) and $Li_2Si_2O_5$(cr) in 20 per cent hydrofluoric acid at 74.7°C were measured by Kracek (1). The authors derived two values of $\Delta_{soln}H$ of Li_2O(cr) from those of LiCl(cr) and Li_2SO_4(cr), presumably employing auxiliary data from (2). We recalculate $\Delta_{soln}H$ of Li_2O(cr) as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal mol^{-1} (sulfate scheme, originally -60.86), using recent $\Delta_f H°(298.15\ K)$ values for LiCl(cr), Li_2SO_4(cr), HCl(aq), H_2SO_4(aq), and Li_2O(cr). The corresponding enthalpy changes, $\Delta_r H°(298.15\ K)$, for the reaction $Li_2O(cr) + 2SiO_2(quartz) = Li_2Si_2O_5(cr)$ are derived as -33.21 and -34.30 kcal mol^{-1}. Adopting the weighted average $\Delta_r H°(298.15\ K)$ = -33.57 kcal mol^{-1} with $\Delta_f H°(Li_2O, cr, 298.15\ K)$ = -143.1 kcal mol^{-1} and $\Delta_f H°(SiO_2, quartz, 298.15\ K)$ = -217.7 kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K)$ = -612.07 kcal mol^{-1} for $Li_2Si_2O_5$(cr). This value is independent of future changes in $\Delta_f H°(298.15\ K)$ of Li_2O(cr) but the values of $\Delta_{soln}H$ and $\Delta_r H°$ are not independent.

The enthalpies of solution of LiOH(cr) and $Li_2Si_2O_6$(cr) in 20 per cent HF(aq) at 50°C were measured by Hatton et al. (3). By use of a reaction scheme similar to that described on the Li_2SiO_3(cr) table, the enthalpy change at 298.15 K for the reaction $2LiOH(cr) + 2SiO_2(cr) + Li_2Si_2O_5(cr) + H_2O(\ell)$ was calculated to be -13.44 kcal mol^{-1}. Incorporating this value with $\Delta_f H°(298.15\ K)$ = -115.84, -217.7 and -68.315 kcal mol^{-1} for LiOH(cr), SiO_2(cr), and $H_2O(\ell)$, respectively, we obtain $\Delta_f H°(Li_2Si_2O_5, cr, 298.15\ K)$ = -612.20±2.0 kcal mol^{-1}, which is in excellent agreement with the adopted value.

Heat Capacity and Entropy

Both heat capacities and $S°(298.15\ K)$ are estimated by comparison with those for $Na_2Si_2O_5$(cr), Na_2O(cr) and Li_2O(cr).

Transition Data

The transition temperature, T_{trs} = 1209 K, is taken from Kracek (4). The author estimated a enthalpy of transition of 1 to 2 cal K^{-1} mol^{-1} based on the arrest in the cooling and heating curves. The value of $\Delta_{trs}H°$ is calculated assuming the enthalpy of transition at 1209 K is 1.5 cal K^{-1} mol^{-1}.

Fusion Data

Incongruent melting of $Li_2Si_2O_5$(cr) at 1033° has been reported by Kracek (5) and Kracek (4). The liquidus temperature of 1034 at the composition 19.92 per cent Li_2O and 80.08 per cent SiO_2, reported by Kracek (4), is adopted as T_{fus}. The enthalpy of melting is evaluated such that $\Delta_{fus}H°(298.15\ K) + \Delta_{trs}H°(298.15\ K)$ = 11.43 kcal mol^{-1}, where the value 11.43 kcal mol^{-1} is the difference between $\Delta_f H°(298.15\ K)$ for $Li_2Si_2O_5$(cr) and $Li_2Si_2O_5(\ell)$. The latter were determined by solution calorimetry by Kracek (see Enthalpy of Formation sections in crystal and liquid tables).

LITHIUM SILICATE ($Li_2Si_2O_5$) LIQUID M_r = 150.0500

$S°(298.15\ K)$ = [160.243] J K^{-1} mol^{-1}

T_{fus} = 1307 K

$\Delta_f H°(298.15\ K)$ = [-2513.068] kJ mol^{-1}

$\Delta_{fus} H°$ = [53.806] kJ mol^{-1}

Enthalpy of Formation

The enthalpies of solution of LiCl(cr), Li_2SO_4(cr), SiO_2(quartz) and $Li_2Si_2O_5$(gl) in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (1). Following the same procedure as described in $Li_2Si_2O_5$(cr) table, we derived the enthalpy changes, $\Delta_r H°(298.15\ K)$, for the reaction $Li_2O(cr) + 2SiO_2(quartz) = Li_2Si_2O_5(gl)$ as -21.78 and -22.87 kcal mol^{-1}. Adopting the weighted average $\Delta_r H°(298.15\ K)$ = -22.14 kcal mol^{-1} with $\Delta_f H°(Li_2O, cr, 298.15\ K)$ = -143.1 kcal mol^{-1} and $\Delta_f H°(SiO_2, quartz, 298.15\ K)$ = -217.7 kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K)$ = -600.640 kcal mol^{-1} for $Li_2Si_2O_5$(gl). This $\Delta_f H°(Li_2Si_2O_5, gl, 298.15\ K)$ value is independent of future changes in $\Delta_f H°(298.15\ K)$ of Li_2O(cr) but the values of $\Delta_{sol} H°$ and $\Delta_r H°$ are not independent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $Na_2Si_2O_5(\ell)$, $Na_2SiO_3(\ell)$ and $Li_2SiO_3(\ell)$. A glass transition temperature at 800 K is assumed, i.e. the heat capacities below 800 K are taken from those for $Li_2Si_2O_5$(cr) and above 800 K are assumed to be constant.

$S°(Li_2Si_2O_5, \ell, 298.15\ K)$ is calculated from $S°(Li_2Si_2O_5, cr, 298.15\ K)$ by adding the entropy of fusion, $\Delta_{fus} S°(1307\ K)$, and the difference in entropy, S°(1307 K)-S°(298.15 K), between the crystal and liquid.

Fusion Data

See the crystal table for details.

PREVIOUS: CURRENT: June 1967

$S°(298.15\ K) = 62.593 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1086\ K$

$\Delta_f H°(0\ K) = -157.57 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -164.56 \pm 1.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation for Li_3N(cr) is derived from the solution calorimetric study of O'Hare and Johnson (1). The reported values have been revised by Osborne and Flotow (2) to correct for the current atomic weight of lithium to give $\Delta_f H°(298.15\ K) = -39.33 \pm 0.26$ kcal mol^{-1}. This uncertainty is derived from the experimental studies.

Previous studies on the measurement of the enthalpy of reaction of lithium with nitrogen (4) and the enthalpy of solution of Li_3N in water (3) are currently thought to be less reliable (1). Both these studies (3, 4) yielded $\Delta_f H°(298.15\ K)$ values of approximately -47 kcal mol^{-1}. Yonco et al. (5) studied the solubility of nitrogen in liquid lithium (468-714 K) and the equilibrium pressure of nitrogen over solid Li_3N (933-1051 K). A 2nd and 3rd law analysis of their reported $\Delta_f G°(T)$ values supports our adopted $S°(298.15\ K)$ value, to within 0.1 cal K^{-1} mol^{-1}, but suggests a 3rd law $\Delta_f H°(298.15\ k)$ value which is more positive by roughly 1.5 kcal mol^{-1} than our adopted value. Emf measurements (823-973 K) of Bonomi et al. (6) gave $\Delta_f G°(T)$ values which are also more positive than our adopted values by roughly 2 kcal mol^{-1} at 900 K. These are suspect since $Li_9N_2Cl_3$ may be involved in the reaction (6). A 2nd and 3rd law analysis of this latter data suggests a $S°(298.15\ K)$ value which is 1.8 cal K^{-1} mol^{-1} smaller than our adopted value and a 3rd law $\Delta_f H°(298.15\ K)$ value which is more positive by 2 kcal mol^{-1} than our adopted value. The $S°(298.15\ K)$ discrepancy is very difficult to reconcile without a unreasonable change in the heat capacity values.

Heat Capacity and Entropy

The thermal functions adopted are those tabulated by Osborne and Flotow (2). These authors determined the heat capacity of a well characterized sample of Li_3N between 5 and 350 K. They used the results of Satoh (7), ice calorimetric data from 273 to 773 K, to extend the heat capacity results to 773 K and then extrapolate to 1086 K, the melting point of Li_3N (1, 5).

As a check, the low temperature experimental heat capacity values are smoothed by fitting the data with orthogonal polynomials over selected overlapping temperature intervals. This fitting procedure gave an $S°(298.15\ K)$ identical to that reported by Osborne and Flotow (2). The ice calorimetric data of Satoh (7) are not extensive enough to reliably define the entire heat capacity dependence from 350 to 1086 K, however the three data prints at 373 K, 578 K, and 773 K are sufficient to define a reasonable temperature dependence.

Magnesium (Mg) Mg_1(ref)

Pearson Notation: hP2

$S°(298.15\ K) = 32.671 \pm 0.10\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 923 \pm 1\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H°(923\ K) = 8.477 \pm 0.418\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted heat capacities are derived from heat capacity (1, 2) and enthalpy data (3) by fitting the experimental data with *orthogonal polynomials over selected overlapping temperature intervals. The temperature region of 1-14 K is described by the* equation: $C_p° = 0.3x10^{-4}\ T + 0.8x10^{-6}\ T^3$ cal K^{-1} mol^{-1}. The S°(298.15 K) value calculated from the polynomials agrees with those of Hultgren et al. (4), Gurvich et al. (5), and CODATA (6) to within 0.01 J K^{-1} mol^{-1}.

Craig et al. (1) measured the heat capacity in the region 12-320 K. Only smoothed values at 10 K intervals were reported and these were based on an incorrect relative atomic mass. Furukawa et al. (4) stated that the heat capacity values should be *multiplied by 24.32/24.22 = 1.0041 to be consistent with the atomic mass of 1954. The current value for the relative atomic mass* of magnesium requires a multiplier of 24.305/24.22 = 1.0035. Our analysis of this smoothed data (with orthogonal polynomials) suggests that the reported values at 18 K and 200 K may be in error.

The heat capacity study of Saba et al. (2) consisted of 37 determinations covering the range 293-548 K. Again only smoothed values at 10 K intervals were given. Using the current relative atomic mass for magnesium, this data should be multiplied by 24.305/24.32 = 0.99938. The enthalpy data of McDonald (3), 6 values in the range 404-914 K, also need to be corrected by a factor of 24.305/24.312 = 0.99971. In the region 300-320 K, the corrected results of Craig et al. (1) lie 0.1% higher and Saba et al. (2) 0.2% lower than the adopted values. The maximum deviation in the enthalpy data of McDonald (3) in comparison with our derived enthalpy values is 0.1%, except for the point at 403 K which is 0.7%. At the melting point, the entropies of JANAF, Hultgren et al. (4), and Gurvich et al. (5) are 15.308, 15.34, and 15.313 cal K^{-1} mol^{-1}, respectively.

Other studies (8-13) are considered for comparison with and confirmation of the adopted values, but they are not included in the polynomial fitting procedure. The heat capacity results of Mannchen and Bornkessel (8), 12-300 K, were presented only graphically and support the results of Craig et al. (1). The quantitative agreement is uncertain since it is not clear if the authors (8) were aware of the correction required for the data of Craig et al. (1). Clusius and Vaughn (9) made experimental heat capacity determinations in the range 11-228 K. These data scatter about the selected values within ±2-4%.

Phase Data

According to Pearson (15), magnesium has a hexagonal-close-packed structure, designated as hP2. In the alkaline earth metal series, only α-Be has a similar structure.

Melting Data

Refer to the Mg(ℓ) single phase table for details.

Sublimation Data

The enthalpy of sublimation of magnesium is the enthalpy of formation of the gas. It is chosen to be that adopted by CODATA (6) based on numerous experimental studies which are discussed in the Mg(g) single phase table (14).

$T_{fus} = 923 \pm 1\ K$

$\Delta_f H°(298.15\ K) = [4.790]\ kJ\ mol^{-1}$

$\Delta_{fus} H°(923\ K) = 8.477 \pm 0.418\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Mg, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Mg, cr, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°(923\ K)$, and the difference in enthalpy, $H°(923\ K) - H°(298.15\ K)$, between the crystal and the liquid. This value is dependent on the arbitrary choice of the liquid phase heat capacity values for temperatures less than 923 K.

Heat Capacity and Entropy

The enthalpy measurements of McDonald (1), 5 observations in the temperature range 954-1263 K, are used to derive a constant liquid phase heat capacity of 8.2 cal K^{-1} mol^{-1}. This constant value is adopted for the entire liquid region and the region between 298.15 and 923 K. Gurvich et al. (13) have adopted the same value. Kubaschewski (2) quoted an unpublished study by Reinartz which gave $C°_p(\ell)$ = 8.1±0.3 cal K^{-1} mol^{-1}. The enthalpies measured by McDonald deviate by -0.2 to +0.3% from the adopted values. The enthalpy study of Awbery and Griffiths (3) extended only 100 K into the liquid region (3 data points) and cannot be used to reliably predict the heat capacity; in addition, their reported enthalpies are 15% lower than the adopted values.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point is adopted as 923±1 K. Charlesworth [4] and Geschneider [5] both adopted this value after critically reviewing the available data in 1964 and 1970, respectively. The primary studies are by Chadwick [6 (923 K)], Jones [7 (920.5 K)], and Haughton and Payne [8 (922±0.5 K)].

The adopted enthalpy of melting, $\Delta_{fus} H°$ = 2.026 kcal mol^{-1}, is derived from the enthalpy study of McDonald (1). Although McDonald (1) reports an uncertainty of ±50 cal mol^{-1}, we feel a value of ±100 cal mol^{-1} reflects better the scatter of the various studies. Kubaschewski (2) quoted values for $\Delta_{fus} H°$ of 2.030±0.080 and 1.830±0.090 kcal mol^{-1} from the unpublished work of Reinartz and a thesis of Wittig, respectively. The calorimetric studies of Ginsberg and Wrigge (9) and the DTA study of Chiotti et al. (10) led to values of 90.6±2 cal/g (2.202±0.049 kcal mol^{-1}) and 1.970±0.016 kcal mol^{-1}, respectively. An enthalpy study of Stull and McDonald (11) led to a heat of melting of 2.14 kcal mol^{-1}; however, this value was thought to be in error due to a container reaction. These reported values all support the adopted value. The enthalpy study of Awbery and Griffiths (3) led to a much lower value of 1.130 kcal mol^{-1}.

Vaporization Data

T_{vap} is calculated as the temperature for which $\Delta_{vap} G°$ = 0 for the liquid vaporizing to the ideal monatomic gas. T_{vap} corresponds to a fugacity of one bar. The enthalpy of vaporization is calculated from the enthalpy of formation of the liquid and the gas at T_{vap}. Vaporization studies are discussed in the ideal gas table (12).

Enthalpy of Formation

The adopted enthalpy of formation values for Mg(g), $\Delta_f H°(298.15\ K)$ = 147.10 ± 0.80 kJ mol^{-1}, is that recommended by CODATA (1). This value was calculated, according to CODATA, from the vapor pressure measurements by Priselkov (673-773 K, 2), Gilbreath (495-658 K, 3), McCreary and Thorn (716-800 K, 4), Pahlman and Smith (650-930 K, 5), and others cited in Hultgren et al. (6).

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Martin and Zulubas (7), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of fitting in these missing levels (for n < 60) and cutting off the summation in the partition function (8) has no effect on the thermodynamic functions to 4000 K. This is a result of the high energy of all levels other than the ground state and the levels listed above; the next excited state is approximately 41197 cm^{-1} above the ground state. Although we list only a few levels, all levels listed by Martin and Zulubas (7) and estimated levels (for n < 60) are considered in the calculation. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the additional states and use of different fill and cutoff procedures (8).

The thermal functions at 298.15 K differ from the CODATA recommendations (1) for two reasons. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas CODATA recommendations are based on 1 atm. Second, small changes, ~0.002 J K^{-1} mol^{-1}, arise due to the use of slightly different values for the fundamental constants.

PREVIOUS: September 1962 (1 atm) CURRENT: September 1983 (1 bar)

MAGNESIUM, ION (Mg^+) IDEAL GAS M_r = 24.30445

$IP(Mg^+, g) = 121267.61 \pm 0.05\ cm^{-1}$
$S°(298.15\ K) = 154.410 \pm 0.02\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 883.65 \pm 1.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [891.047]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	$\varepsilon_i\ cm^{-1}$	g_i
$^2S_{1/2}$	0	2
$^2P_{1/2}$	35669.31	2
$^2P_{3/2}$	35760.88	4

Enthalpy of Formation

$\Delta_f H°(Mg^+, g, 0\ K)$ is calculated from $\Delta_f H°(Mg, g, 0\ K)$ (1) using the spectroscopic value of $IP(Mg) = 61671.02 \pm 0.10\ cm^{-1}$ ($737.749 \pm 0.001\ kJ\ mol^{-1}$) from Martin and Zolubas (2). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, $1\ cm^{-1} = 0.01196266\ kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Mg^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Mg, g, 0\ K)$ by using IP(Mg) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Mg(g), $Mg^+(g)$, and $e^-(g)$. $\Delta_r H°(Mg + Mg^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by $-6.197\ kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Martin and Zolubas (2), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (6) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first two excited states; the next excited state is $69804.95\ cm^{-1}$ above the ground state. Since inclusion of these higher excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first two excited states. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (6).

MAGNESIUM NITRIDE (MgN) IDEAL GAS M_r = 38.3117

$S°(298.15\ K)$ = [224.835] J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = [289.04 ± 25.1] kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [288.70 ± 25.1] kJ mol^{-1}

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
[$^2\Pi$]	0	[4]

ω_e = [700] cm^{-1} $\omega_e x_e$ = [4.8] cm^{-1} σ = 1
B_e = [0.5542] cm^{-1} α_e = [0.0052] cm^{-1} r_e = [1.85] Å

Enthalpy of Formation

$\Delta_f H°(MgN, g, 298.15\ K)$ was estimated from bond strengths using MgO and comparison with analogous pairs of compounds such as, PN and PO, and also the bond strengths of C-N and C-O in organic compounds.

Heat Capacity and Entropy

The r_e value for MgN was estimated from MgO by comparison with similar pairs PO and PN, SiO and SiN, and AlO and AlN. Using Guggenheimer (1). ω for MgO was found to lie between the single and multiple bonding cases. Magnesium nitride was assumed to be similar to MgO and ω_e 700 cm^{-1} was obtained. It was assumed that the $x_e\mu^{1/2}$ value for MgN was equal to that for MgO thus giving $\omega_e x_e$ = 4.8 cm^{-1}. B_e was calculated from r_e. The α_e value was calculated from B_e, ω_e and $\omega_e x_e$.

PREVIOUS: March 1964 (1 atm) CURRENT: March 1964 (1 bar)

$S°(298.15\ K) = 26.924 \pm 0.08\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 3105 \pm 30\ K$

$\Delta_f H°(0\ K) = -597.060 \pm 0.63\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -601.241 \pm 0.63\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [77.822 \pm 16.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is based on oxygen-bomb calorimetry of Holley and Huber (1) and HCl-solution calorimetry of Shomate and Huffman (2). The reported values of -143.70 ± 0.12 (1) and -143.84 ± 0.05 (2) kcal mol^{-1} become $\Delta_f H°(298.15\ K)$ = -143.61 ± 0.12 and -143.78 ± 0.08 kcal mol^{-1} when adjusted to 1969 atomic weights. We adopt the median value of -143.70 ± 0.15 kcal mol^{-1}.

NBS (3) adopted -143.81 kcal mol^{-1} for macrocrystalline periclase, based on the data of Shomate and Huffman (2) converted to 1961 atomic weights. Parker (3) preferred the data of Shomate and Huffman because of the inference that their sample corresponded more closely to the macrocrystalline standard state. New $\Delta_{sln} H°$ data (4) suggest that excess energy of up to ~1.1 kcal mol^{-1} arises mainly from disorder (defects) in MgO rather than from high surface area and small particle size. Since the excess energy is eliminated at T>~1000°C (4), it is unlikely that this effect would bias the combustion data of Holley and Huber (1).

Other data for $\Delta_f H°$ were reviewed by Parker (3). New measurements exist for $\Delta_{sln} H°$ of MgO (4) and Mg (5), but we have not attempted to derive $\Delta_f H°$ because of difference in the final states of the solutions.

Heat Capacity and Entropy

$C_p°$ below 270 K is based on data (3-270 K) for single crystals measured by Barron et al. (6). Values above 270 K are from a constrained fit of $C_p°$ (6) and enthalpies (373-1173 K) of fused MgO measured in a Bunsen ice calorimeter by Victor & Douglas (7). S°(298.15 K) is obtained from $C_p°$ based on a negligible extrapolation to absolute zero.

Maximum deviatons of the $C_p°$ data (6) from the adopted curve are ±1.7% near 15 K, ±1.0% near 20 K, ±0.4% near 40 K, and ~0.2% at higher temperatures. Gmelin (8) later reported smoothed $C_p°$ values (2-320 K) derived from data for MgO sintered at high temperature. These values are in good agreement with the adopted curve except from 70 to 140 K, where deviations are all positive and reach a maximum of almost 7% at 90 K. Gmelin's values gave S°(298.15 K) = 6.50, i.e., higher by ~0.06 cal $K^{-1}\ mol^{-1}$. Larger positive deviations in $C_p°$ exist at all temperatures (20-301 K) for the non-standard state MgO used by Giauque and Archibald (9). Their sample was prepared from hydroxide in vacuo at ~350°C and was not annealed at high temperature. The microcrystalline product presumably was disordered, leading to excess $C_p°$ and S°(298.15 K) = 6.66 cal $K^{-1}\ mol^{-1}$. Limited data of Parks and Kelley (10) for fused MgO tend to confirm the adopted curve.

Deviations of the enthalpy data from the adopted curve are ±0.15% (7, 373-1173 K), -0.3 ± 0.3% (11, 402-1799 K), +0.8 ± 0.9% (12, 370-1591 K) and -2.8 to +1.0% (13, equation for 1200-2500 K). Microcalorimetric $C_p°$ data (14, 305-455 K) agree with the adopted curve at the mid-temperature but have a temperature derivative which is too small.

Fusion Data

See the liquid table for details.

PREVIOUS: December 1965 CURRENT: December 1974

$S°(298.15\ K) = [48.366]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3105 \pm 30\ K$

$\Delta_f H°(298.15\ K) = [-532.609]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [77.822 \pm 16.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(MgO, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(3105 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is assumed to be 16 cal K^{-1} mol^{-1} except below the glass transition (2100 K) where $C_p°(\ell)$ is taken equal to $C_p°(cr)$. Enthalpy data yield $C_p° \geq 19$ cal K^{-1} mol^{-1} for liquid BeO (1) but there may be a positive bias due to volatilization. S°(298.15 K) is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Documented values for T_{fus} (in °C, IPTS-48) include 2800±20 (2), 2827±20 (3) and 2852 (4, 5). We adopt the median value (3) which becomes 2832°C = 3105 K on IPTS-68.

Calorimetric data for $\Delta_{fus}H°$ are not available. Kelley (6) derived an apparent $\Delta_{fus}H°$ = 18.5 kcal mol^{-1} at T_{fus} = 2915 K from liquidus data for the $MgO-ZrO_2$ binary (7). The old (7) and new (8, 9) data for $MgO-ZrO_2$ imply gross non-ideality which makes the system unsuitable for obtaining the enthalpy of fusion. Apparent $\Delta_{fus}H°$ values ranging from 8 to 30 kcal mol^{-1} are obtained from more suitable binary systems (9, 10) involving CaO, Al_2O_3, Cr_2O_3, PuO_2 and UO_2. These values are so uncertain that we assume $\Delta_{fus}H°$ = 18.6 kcal mol^{-1} based on Δ_{fus} = 6 cal k^{-1} mol^{-1}. Δ_{fus} H° = 20 kcal mol^{-1} was measured calorimetrically for BeO (1), but the crystal is hexagonal or tetragonal rather than cubic as in the case of MgO.

Vaporization Data

Vaporization rates based on weight loss at T_{fus} were repoted by Noguchi (8) for MgO and six other refractory oxides. Vaporization of MgO near 2000 K has been studied by Langmuir-torsion (11), Langmuir-weight-loss (12, 13), Knudsen-mass-spectrometric (14), Knudsen-effusion (15) and transpiration (15, 16) methods. Vaporization near 2000 K is primarily to the elements (14), Mg(g) and presumably O(g) and O_2(g), rather than to MgO(g). Quantitative interpretation of the vaporization species is uncertain. The adopted tables (1) predict that MgO(g) is insignificant near 2000 K but should become one of the significant components of the vapor near T_{fus}.

Enthalpy of Formation

We adopt D_0^0 = 80±6 kcal mol^{-1} and $\Delta_f H°(298.15\ K)$ = 13.9±6 kcal mol^{-1} based on equilibria analyzed below. Greatest weight is given to mass-spectrometric data (11) for reactions A and B. We give "<" or ">" for $\Delta_f H°$ and D_0^0 values which may have a systematic bias. The JANAF differences in $\Delta_f H°(298.15\ K)$ for WO_3-WO_2 (3) may be biased by as much as -3.5 kcal mol^{-1}, leading to a positive bias in D_0^0 from reaction B. Mass spectra (12) and transpiration data (13) yield an upper limit to D_0^0; we neglect $Mg(OH)_2$ and MgOH which probably are important in (13). Cotton and Jenkins (15) concluded that hydroxides were negligible in their H_2-O_2-N_2 flames; we doubt this conclusion and presume that reaction D yields an upper limit to D_0^0. Our adopted value is comparable with those of Richards et al. (7, 1) and Brewer & Rosenblatt (16), considering the difference in functions for MgO.

Other published values of D_0^0 are dismissed for reasons cited in critical reviews (17, 18, 11). Schofield's criticism (17) of flame studies is supported by new evidence for importance of hydroxides (3, CaO, g). Inadequate allowance for hydroxides may bias a recent flame result of D_0^0 = 88±2.3 kcal mol^{-1} (19); furthermore, we cannot firm this D_0^0 from the published information. D_0^0 = 83 kcal mol^{-1} was derived (20) by fitting an electronegativity potential function to X'Σ. This state is predicted (18, 4, 11) to dissociate to excited state O(^{1}D) at 45.4 kcal mol^{-1}. Theoretical calculations (21) support this prediction. Linear Birge-Sponer extrapolation yields a very low estimate for D_0^0, just as it does for the alkali halides (18), unless $X^1\Sigma$ fails to dissociate to O^1(D) as predicted.

Heat Capacity and Entropy

Electronic levels (T_0) and vibrational-rotational constants of observed states are from Rosen (1) and other recent sources (3-10). States are listed in the isoconfigurational order given by Schamps and Lefebvre-Brion (4). Designations (3) of the new E, F and G states are based on theoretical calculations (4). Field (2) concluded that calculations (4-6) of the isoconfigurational $A^1\Pi$-$^3\Pi$ separation should be adequate for estimating the low-lying $^3\Pi$ state. The other potentially low-lying state ($^3\Sigma^+$) is estimated (4) similarly from isoconfigurational $B^1\Sigma^+$. Higher estimated levels are also based on calculations (4). Vibrational-rotational constants are estimated in isoconfigurational groups by comparison with BeO, CaO, SrO and BaO (3). Low-lying levels and their vibrational-rotational constants cause marked changes in the thermodynamic functions, which are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_{tt} \sum Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$.

PREVIOUS: December 1974 (1 atm) CURRENT: December 1974 (1 bar)

$S°(298.15\ K) = 67.77 \pm 0.8\ J\ K^{-1}\ mol^{-1}$
$T_{trs1} = 903\ K$
$T_{trs2} = 1258\ K$
$T_{fus} = 1850 \pm 2\ K$

$\Delta_f H°(0\ K) = -1539.79 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1548.92 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = 0.67\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = 1.632\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [75.312 \pm 20.9]\ kJ\ mol^{-1}$

Enthalpy of Formation

Torgeson et al. (1) report a $\Delta_r H°(298.15\ K) = -8.69 \pm 0.15\ kcal\ mol^{-1}$ for reaction (a). They used a hydrofluoric acid solution calorimeter and measured the enthalpies of solution of each component. They appear to have made the water-absorption correction to the enthalpy of solution of SiO_2(cr) in the wrong direction. We reverse the correction so that the new $\Delta_{sol}H$ almost overlaps the range observed by King (11). We derive $\Delta_f H°(MgSiO_3, cr, 298.15\ K) = -370.20 \pm 1.0\ kcal\ mol^{-1}$ using the $\Delta_f H°(298.15\ K)$ of MgO(cr) and SiO_2(cr, low quartz) from the JANAF tables.

Reesman et al. (2) calculated a $\Delta_r G°(298.15\ K) = 23.72\ kcal\ mol^{-1}$ for reaction (b) using aqueous solubility data. We use the $\Delta_f G°(298.15\ K)$ of $H_2O(\ell)$ and $OH^-(aq)$ from source 3, $\Delta_f G°(298.15\ K)$ of $H_4SiO_4(aq)$ from source 4 and $\Delta_f G°(298.15\ K)$ of $Mg^{++}(aq)$ from source 5 and we obtain a $\Delta_f G°(MgSiO_3, cr, 298.15\ K) = -352.534\ kcal\ mol^{-1}$. We derive $\Delta_f H°(MgSiO_3, cr, 298.15\ K) = -373.293\ kcal\ mol^{-1}$ using the above $\Delta_f G°(298.15\ K)$ of $MgSiO_3$(cr) and the entropies of Mg(cr), Si(cr) and O_2(g) from the JANAF tables.

We choose the enthalpy of formation derived from the result of Torgeson et al. (1) which is considered to be better since it relates directly to the oxides. Also the $\Delta_f G°(MgSiO_2, \ell, 1873\ K)$ thus calculated is in very good agreement with that derived from the activities of SiO_2 and MgO (in the SiO_2 - MgO system) measured by Rein et al. (6). The $\Delta_f H°(MgSiO_3, cr, 298.15\ K)$ derived from the work of Reesman et al. is less accurate and involves uncertainties in the auxiliary data used to calculate the value.

Source	Method	Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_r G°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	HF solution calorimeter	(a) $MgO(cr) + SiO_2(cr) = MgSiO_3(cr)$	-8.7±0.15		-370.20
(2)	Aqueous solubility	(b) $MgSiO_3(cr) + 3H_2O(\ell) = Mg^{++}(aq) + H_4SiO_4(aq) + 2OH^-(aq)$		23.72	-373.3

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53 - 295 K) of Kelley (7). Wagner (8) measured the average heat capacities in the temperature range 580 - 1570 K. Using his data we derive the high temperature heat capacities which are joined smoothly with the low temperature values by a constrained fitting technique. The $C_p°$ values at 903 - 1258 K and above 1258 K are derived as 28.762 and 29.262 cal K^{-1} mol^{-1}, respectively, by assuming that the data of Wagner (8) pertain to the stable phase in these regions. The entropy is based on $S°(50\ K) = 0.49\ cal\ K^{-1}\ mol^{-1}$.

Transition Data

$T_{trs1} = 903\ K$ is obtained from Boyd et al. (9). The authors determined the phase diagram boundary at high pressures and extrapolated to one atmosphere. $T_{trs2} = 1258\ K$ is taken from Atlas (10). Below 903 K the phase is known as clinoenstatite. Between 903 and 1258 K it is rhombic enstatite and above 1258 K it is protoenstatite. We calculate $\Delta_{trs1}H°$ and $\Delta_{trs2}H°$ (from dT/dP (slopes of the inversion) = 2.6/kbar and 84/kbar reported by Boyd et al. (9, 13) and from the densities of clinoenstatite (3.210 gm/cc) and rhombic enstatite (3.208 gm/cc) reported by Stephenson et al. (11) and the density of protoenstatite (3.10 gm/cc) reported by Smith (12).

Fusion Data

See the liquid table for details.

PREVIOUS: September 1964 CURRENT: December 1967

MAGNESIUM SILICATE ($MgSiO_3$) LIQUID M_r = 100.3887

$S°(298.15\ K)$ = [92.515] J K^{-1} mol^{-1}
T_{trs1} = 903 K
T_{trs2} = 1258 K
T_{fus} = 1850 ± 2 K

$\Delta_f H°(298.15\ K)$ = [-1494.862 ± 20.9] kJ mol^{-1}
$\Delta_{trs1} H°$ = 0.67 kJ mol^{-1}
$\Delta_{trs2} H°$ = 1.632 kJ mol^{-1}
$\Delta_{fus} H°$ = [75.312 ± 20.9] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(MgSiO_3, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MgSiO_3, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1850\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 900 K. Below 900 K the heat capacity is obtained from the heat capacity of the crystal. Above 900 K the heat capacity is assumed constant and estimated as 35 cal K^{-1} mol^{-1} or 7 cal K^{-1} g-atom^{-1}. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Transition Data

See the crystal table for details.

Fusion Data

T_{fus} is taken from Bowen and Andersen (1). $MgSiO_3(cr)$ melts incongruently in the temperature range 1830 - 1850 K at atmospheric pressure. $\Delta_{fus} H°$ is estimated from the phase diagrams of the $MgSiO_3$ - TiO_2 system reported by MacGregor (2). The phase diagrams were determined at 10 and 20 kbars pressure where $MgSiO_3(cr)$ melts congruently.

Magnesium Silicate ($MgSiO_3$) $Mg_1O_3Si_1$(cr,l)

MAGNESIUM TITANIUM OXIDE ($MgTiO_3$) CRYSTAL M_r = 120.1832

$S°(298.15\ K) = 74.56 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1953 \pm 20\ K$

$\Delta_f H°(0\ K) = -1563.26 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1572.56 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [90.374]\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation is calculated from $\Delta_r H°(298.15\ K) = -6.35 \pm 0.25\ kcal\ mol^{-1}$ for the reaction $MgO(cr) + TiO_2(rutile) \rightarrow MgTiO_3(cr)$ measured by Kelley et al. (1), using a solution calorimetric method. For the same reaction a value of $\Delta_r H°(298.15\ K) = -5.5 \pm 0.1\ kcal\ mol^{-1}$ was obtained with a calorimetric bomb method by Ronfilov and Feodos'ev (2). These authors used the oxidation of lampblack in order to initiate the formation of the titanate from the oxides. Unfortunately the desired enthalpy of reaction was only 1.2 to 1.5 percent of the total measured heat, and consequently this result appears to be more uncertain than that measured by the solution calorimetric method.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52 - 296 K) of Shomate (3). High temperature enthalpies have been measured (402 - 1720 K) by Naylor and Cook (4). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S°(52\ K) = 0.45\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

See the liquid table for details.

MAGNESIUM TITANIUM OXIDE ($MgTiO_3$) LIQUID M_r = 120.1832

$S°(298.15\ K) = [111.082]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1953 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [-1497.631 \pm 6.3]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [90.374]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(MgTiO_3, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MgTiO_3, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1953\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300 K. The heat capacity below 1300 K is obtained from the heat capacity of the crystal. Above 1300 K the heat capacity is assumed constant and estimated as 39 cal K^{-1} mol^{-1} or 7.8 cal K^{-1} $g\text{-}atom^{-1}$. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting point at 1903 K. The $\Delta_{fus} H°$ is estimated from those of $Na_2O \cdot 2TiO_2$ and $Na_2O \cdot TiO_2$ observed by Naylor (3) and $CaO \cdot TiO_2 \cdot SiO_2$ observed by King (4).

PREVIOUS: CURRENT: June 1967

$S°(298.15\ K) = 91.40 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1400\ K$

$\Delta_f H°(0\ K) = -1250.40 \pm 20.9\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1261.79 \pm 20.9\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 14.644\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°(298.15\ K) = -301.6 \pm 5\ kcal\ mol^{-1}$ was calculated from the $\Delta_r H°(298.15\ K) = 63.3 \pm 5\ kcal\ mol^{-1}$ for the reaction $MgO(cr) + SO_3(g) = MgSO_4(cr)$. The value of $\Delta_r H°(298.15\ K)$ was calculated by the 3rd law method using the equilibrium data obtained from a transpiration study by Knopf and Staude (1). In addition Marchal (2) measured the total pressure of $SO_3(g)$, $SO_2(g)$ and $O_2(g)$ above $MgSO_4(cr)$ and partial pressures were obtained by application of the SO_3-SO_2 equilibrium data. Another value of $\Delta_f H°(MgSO_4, cr, 298.15\ K)$ may be derived from the measured enthalpy of solution of $MgSO_4(cr)$ by Thomsen (3) and the measured enthalpies of mixing of $MgCl_2(aq, 200\ H_2O)$ with $H_2SO_4(aq, 200\ H_2O)$ and $MgSO_4(aq, 200\ H_2O)$ with $2HCl(100\ H_2O)$ by Thomsen (4).

Source	Reaction	T/K	Drift cal K^{-1} mol^{-1}	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	$MgO(cr) + SO_3(g) = MgSO_4(cr)$	1144-1313	0.514	63.284	-301.574
(2)	$MgO(cr) + SO_3(g) = MgSO_4(cr)$	1223-1428	0.525	72.394	-310.867
(3)	$MgSO_4(cr) = MgSO_4(aq, 200\ H_2O)$	298.15		-20.84	
(4)	$MgCl_2(aq, 200\ H_2O) + H_2SO_4(aq, 200\ H_2O) = MgSO_4(aq, 200\ H_2O) + 2HCl(aq, 100\ H_2O)$	298.15		- 3.52	-305.1*

*Combination of the reactions 3 and 4 with the following $\Delta_f H°(298.15\ K)$: $H_2SO_4(aq, 200\ H_2O) = -212.387$, $HCl(aq, 100\ H_2O) = -39.74$ and $MgCl_2(aq, 200\ H_2O) = -189.5\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The low temperature heat capacities 53.3-295.4 K were measured by Moore and Kelley (4). The heat capacities in the temperature range 298-1400 K were estimated from the equation $MgSO_4(cr) = CaSO_4(cr) + MgO(cr) - CaO(cr)$. $CaSO_4(cr)$ and $CaO(cr)$ $C°_p$ were calculated using the equation $C°_p = 16.78 + 23.60 \times 10^{-3}T$ and $C°_p = 11.67 + 1.08 \times 10^{-3}T - 1.56 \times 10^5 T^{-2}$ respectively, Kelley (5). The heat capacity of MgO(cr) was calculated from the correlation of the low temperature heat capacities. The values from the two sources join smoothly at 298.15 K. Above the melting point (1400 K) the heat capacity was graphically extrapolated. The entropy was calculated at 50.12 K using the Debye and Einstein function D(242/T)+2E(378/T)+2E(866/T)+E(1683/T) given by Moore and Kelley (4). The value of $S°(50.12\ K) = 1.08\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} and $\Delta_{fus} H°$ from Kelley (6).

MAGNESIUM SULFATE ($MgSO_4$) LIQUID M_r = 120.3626

$S°(298.15\ K)$ = [102.125] J K^{-1} mol^{-1}

T_{fus} = 1400 K

$\Delta_f H°(298.15\ K)$ = [-1246.587] kJ mol^{-1}

$\Delta_{fus} H°$ = 14.644 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(MgSO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MgSO_4, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1400\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition was assumed at 1000 K. The heat capacity below 1000 K was obtained from the heat capacity of the crystal. Above 100 K the heat capacity was assumed constant and estimated as 38.0 cal K^{-1} mol^{-1} by comparison with those for $MgCl_2(\ell)$, $KCl(\ell)$ and $K_2SO_4(\ell)$. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Magnesium Sulfate ($MgSO_4$) $Mg_1O_4S_1$(cr,l)

MAGNESIUM TUNGSTEN OXIDE ($MgWO_4$) CRYSTAL M_r = 272.1526

$S°(298.15\ K) = 101.19 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

T_{fus} = Unknown

$\Delta_f H°(0\ K) = -1505.74 \pm 33.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ k) = -1515.86 \pm 33.5\ kJ\ mol^{-1}$

$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

Rezukhina and Levitskii (1) measured the emf, E = 0.2433 - 0.0001264T, for the cell reaction MgO(cr) + W(cr) + $3Fe_{0.95}O$(cr) = $MgWO_4$(cr) + 2.85 Fe(cr), in the temperature range 1220 - 1370 K. Incorporating the results with auxiliary thermal data, the authors obtained $\Delta_r G° = -224{,}370 + 65.67T$ (cal $K^{-1}\ mol^{-1}$) for MgO(cr) + W(cr) + $3/2 O_2$(g) + $MgWO_4$(cr). 3rd law analysis of the $\Delta_r G°$ equation gives $\Delta_r H°(298.15\ K) = -218.6$ kcal mol^{-1}, from which the adopted $\Delta_f H°(MgWO_4, cr, 298.15\ K) = -362.3$ kcal mol^{-1}, is calculated. The 2nd law analysis gives $\Delta_f H°(MgWO_4, cr, 298.15\ K) = -372.7$ kcal mol^{-1}. The drift is 8.0 cal $K^{-1}\ mol^{-1}$.

Rezukhina, et. al. (2) determined the Gibbs energy changes $\Delta_r G° = 51{,}300 - 27.67T$ (cal $K^{-1}\ mol^{-1}$) for the reaction $MgWO_4$(cr) + $3H_2$(g) + MgO(cr) + W(cr) + $3H_2O$(g) in the temperature range 1073 K - 1273 K by a circulation method. This leads to heats of formation of -366.1 kcal mol^{-1} by the 3rd law method and -377.2 kcal mol^{-1} by the 2nd law method. Both determinations were performed by Rezukhina and his co-workers, but they considered the data obtained by the emf method to be more reliable than that derived from heterogeneous equilibria.

Heat Capacity and Entropy

Low temperature heat capacities, 52.92 - 296.09 K, were measured calorimetrically by King and Weller (3). The heat capacities above 300 K are estimated by comparison with those of $CaWO_4$(cr) (4), CaO(cr) (5) and MgO(cr) (6). These two sets of data are joined smoothly at 298.15 K by a graphical method.

The entropy, S°(298.15 K) = 21.184 cal $K^{-1}\ mol^{-1}$, is taken from King and Weller (3), based on an extrapolation of S°(51 K) = 1.27 cal $K^{-1}\ mol^{-1}$. No spin-magnetic entropy is predicted below 51 K based on the diamagnetism observed by Gerasimov (7).

PREVIOUS: June 1963 CURRENT: March 1967

$S°(298.15\ K) = 135.60 \pm 6.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1963 \pm 20\ K$

$\Delta_f H°(0\ K) = -2495.43 \pm 10.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2509.35 \pm 10.5\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [146.440]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from $\Delta_r H°(298.15\ K) = -4.45 \pm 0.45$ kcal mol^{-1} for the reaction $MgO(cr) + 2TiO_2(rutile) = MgTi_2O_5(cr)$ measured by Kelley et al. (1), using a solution calorimetric method. The uncertainty of ±2.5 kcal mol^{-1} assigned to the enthalpy of formation is due primarily to TiO_2(rutile).

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52-296 K) of Todd (2). High temperature enthalpies have been measured (397-1812 K) by Orr and Coughlin (3). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S°(51\ K) = 1.11$ cal K^{-1} mol^{-1}.

Kelley et al. (1), suggested that there may be a zero-point entropy due to randomness of the cations. The authors estimated $S°(0\ K)$ from the following alternative assumptions: (a) all the Mg and Ti ions are randomly distributed among the latice sites giving 3.79 cal K^{-1} mol^{-1} and (b) all the Mg and one-half of the Ti ions are randomly distributed giving 2.75 cal K^{-1} mol^{-1}. These assumptions were proposed in order to make $MgTi_2O_5$ stable relative to $MgTiO_3$ at high temperatures. Phase data of Massazza and Sirchia (4), indicate that $MgTi_2O_5$ melts congruently at 1963±20 K and that there is a temperature range. To make $\Delta_r G°(1800\ K) < 0$ would require that $S°(0\ K) \geq 0.35$ cal K^{-1} mol^{-1}. We adopt a compromise zero-point entropy of 2 cal K^{-1} mol^{-1} between the upper (3.79 cal K^{-1} mol^{-1}) and the lower (0.35 cal K^{-1} mol^{-1}) limits.

Fusion Data

See the liquid table for details.

PREVIOUS: June 1961 *CURRENT: June 1967*

MAGNESIUM TITANIUM OXIDE ($MgTi_2O_5$) LIQUID M_r = 200.0620

$S°(298.15\ K)$ = [197.783] J K^{-1} mol^{-1}

T_{fus} = 1963 ± 20 K

$\Delta_f H°(298.15\ K)$ = [-2382.31 ± 8.4] kJ mol^{-1}

$\Delta_{fus} H°$ = [146.440] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(MgTi_2O_5, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(MgTi_2O_5, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(1963 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300 K. Below 1300 K the heat capacity is obtained from the heat capacity of the crystal. Above 1300 K the heat capacity is assumed constant and estimated as 62.4 cal K^{-1} mol^{-1} or 7.8 cal K^{-1} g-atom^{-1}. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The congruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting at 1925 K. The $\Delta_{fus} H°$ is estimated from those of $Na_2O \cdot 2TiO_2$ and $Na_2O \cdot TiO_2$ observed by Naylor (3) and $CaO \cdot TiO_2 \cdot SiO_2$ observed by King (4).

PREVIOUS: CURRENT: June 1967

$S°(298.15\ K) = 50.33 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -344.65 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -345.72 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

Sabatier (1) determined $\Delta_r H°(286\ K) = -37.8 \pm 1.0$ kcal mol^{-1} while Mourlot (2) determined $\Delta_r H°(291\ K) = -38.0 \pm 1.0$ kcal mol^{-1} for MgS(cr) + 2 HCl(aq, 100 H_2O) + $MgCl_2$(aq, 100 H_2O) + H_2S(aq). We derive $\Delta_f H°$(MgS, cr, 298.15 K) = -83.0±2.0 kcal mol^{-1} and $\Delta_f H°$(MgS, cr, 298.15 K) = -82.8±2.0 kcal mol^{-1} respectively based on the following auxiliary data: $\Delta_f H°$(HCl·100 H_2O, aq, 298.15 K) = -39.657 kcal mol^{-1} (3), $\Delta_f H°$(H_2S, aq, 298.15 K) = -9.5 kcal mol^{-1} (3), and $\Delta_f H°$($MgCl_2$·100 H_2O, aq, 298.15 K) = -190.59 kcal mol^{-1}(4). The uncertainty reflects the correction to 298.15 K and the ambiguity of the exact solution composition. Von Wartenberg (5) measured $\Delta_r H°(293\ K) = -33.95 \pm 0.79$ kcal mol^{-1} for MgS(cr) + 2 HCl(30 H_2O, aq) + $MgCl_2$(30 H_2O, aq) + H_2S(g). We derive $\Delta_f H°$(MgS, cr, 298.15 K) = -82.0±1.0 kcal mol^{-1} based on the following auxiliary data: $\Delta_f H°$(HCl·30 H_2O, aq, 298.15 K) = -39.357 kcal mol^{-1} (3), $\Delta_f H°$(H_2S, g, 298.15 K) = -4.90 kcal mol^{-1} (3), and $\Delta_f H°$($MgCl_2$·30 H_2O, aq, 298.15 K) = -189.78 kcal mol^{-1} (4).

Kapustinskii and Korshunov (6) performed calorimetric measurements of the enthalpy of formation of MgS(cr) from the pure elements. They determined $\Delta_f H°(298.15\ K) = -84.33 \pm 0.27$ kcal mol^{-1} for Mg(cr) + S(cr, rhombic) = MgS(cr).

Our analyses of equilibrium studies of Curlock and Pidgeon (7) and of Dewing and Richardson (8) are given below. The two studies are in reasonable agreement. The 3rd law $\Delta_r H°(298.15\ K)$ may be in error by as much as 0.5 kcal mol^{-1} since the Gibbs energy functions employed in the calculations are partially based on estimated high temperature $C_p°$ values.

Source	Method	Data Points	Reaction[a]	T/K	δS cal K^{-1} mol^{-1}	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Curlock (7)	Equilibrium	6	A	1180-1483	-0.60±0.45	-8.49±0.59	-9.19±0.24	-81.59±0.4
Dewing (8)	Equilibrium	6	A	1267-1768	-2.23±0.22	-5.53±0.38	-8.73±1.01	-82.05±1.2

[a]Reaction: A) MgS(cr) + H_2O(g) = MgO(cr) + H_2S(g)

Our adopted value is based on a weighted average of all the data.

Heat Capacity and Entropy

Stull et al. (9) measured the low temperature heat capacities in an adiabatic calorimeter from 15 - 320 K. Their smooth values are adopted in the tabulation. The entropy $S°(298.15\ K) = 12.03 \pm 0.1$ cal K^{-1} mol^{-1} is based on $S° = 0.010$ cal K^{-1} mol^{-1} at 15 K (9). The $C_p°$ values above 320 K are estimated by graphical extrapolation combined with method B of Kubaschewski et al. (10).

Fusion Data

MgS melts above 2300 K (11) and no other literature melting data are available.

Enthalpy of Formation

Colin et al. (1) searched unsuccessfully for gaseous MgS in a Knudsen effusion mass-spectrometric experiment. They set the upper limit $D_0^0(MgS, g) = 55$ kcal mol^{-1}. There are no other equilibrium or positive mass spectrometric data involving MgS(g); consequently $D_0^0(MgS, g)$ must be estimated. The Birge-Sponer extrapolation is of little utility in this case. Gaydon (2) has gone into great detail concerning the problems inherent in linear-Birge-Sponer extrapolations (LBX) on the oxides and sulfides of the alkaline earths. The normal LBX yields $D_0^0(MgS, g) = 73$ kcal mol^{-1}. When adjusted for ionic character with the Hildenbrand correction (3), $D_0^0(MgS, g) = 65$ kcal mol^{-1}. The ground state of MgS cannot dissociate into ground state atoms. After correcting for the excited atomic products, $D_0^0(MgS, g) = 42$ kcal mol^{-1}. A more reliable method of estimation is that of Hauge and Margrave (4) based on the observation that the ratio $D_{MS}K_{MO}/D_{MO}K_{MS}$ is very similar for elements within a given group. Based on data involving known bond energies and force constants of the gaseous diatomic oxides and sulfides, we calculate $D_0^0(MgS, g) = 78 \pm 10$ kcal mol^{-1}. Dissociation energies of the alkaline earth monoxides were taken from Srivastava (5), dissociation energies for the alkaline earth sulfides were taken the JANAF Thermochemical Tables (6) and force constants were calculated from spectroscopic data of Barrow and Cousins (7). Further comparisons of vapor pressures and enthalpies of sublimation for the other alkaline earth oxides and sulfides (6) suggest lower values of $D_0^0(MgS, g)$ than the Hauge and Margrave method leads to. We adopt $D_0^0(MgS, g) \leq 66 \pm 16$ kcal mol^{-1}. Using auxiliary JANAF data (6), we calculate $\Delta_f H°(MgS, g, 298.15\ K) = 34.71 \pm 16$ kcal mol^{-1}.

Heat Capacity and Entropy

The spectroscopic constants of the observed states, taken from Marcano and Barrow (8) for the isotopic species $Mg^{24}S^{32}$, are corrected to account for the natural abundances of the elements. Other low-lying electronic states and their vibrational-rotational constants are estimated in isoconfigurational groups by analogy with MgO (6) and from trends observed in the known states of the other alkaline-earth oxides and sulfides (6). Uncertainty in the energy and molecular constants for the estimated states may contribute significantly, perhaps as much as 1.0 cal $K^{-1}\ mol^{-1}$ to the entropy at 298.15 K.

The ground state of gaseous MgS is taken as $^1\Sigma^+$. There should be low-lying triplet states. A $^1\Pi$ state is predicted for MgS at 3000 cm^{-1} based on experimentally observed $^1\Pi$ states for MgO (9), BeO (6), and BeS (10). The corresponding triplet, $^3\Pi$, is assumed to lie 1000 cm^{-1} lower in energy based on trends in the triplet-singlet splitting observed by Field (11) for the alkaline-earth oxides. Similar trends in the triplet-singlet splitting of the isoconfigurational Σ states are used to place the $^3\Sigma^+$ state 6000 cm^{-1} below the experimentally observed (8) $A^1\Sigma^+$ state. By analogy with MgO (6) we do not feel that a $^1\Delta$ state exists below 25000 cm^{-1}. The thermodynamic functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \sum_i Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$.

(a) $+1.6244 \times 10^{-2} (v + 1/2)^3 - 6.106 \times 10^{-4} (v + 1/2)^4$.
(b) $+1.0679 \times 10^{-4} (v + 1/2)^2 - 9.6831 \times 10^{-6} (v + 1/2)^3$.
(c) $-3.0768 \times 10^{-8} (v + 1/2) + 2.1344 \times 10^{-8} (v + 1/2)^2$.
(d) These values are estimated based on the theoretical potential curves of Stevens and Krauss (4).

Enthalpy of Formation

The ground state dissociation energy for $^{24}Mg_2$ was determined by Li and Stwalley (2) to be 404.1±0.5 cm^{-1}. This value was corrected to natural abundance Mg_2 with the result D_0^0 = 404.3 cm^{-1}. Using this value and the recommended value for $\Delta_f H°(Mg, g, 0\ K)$ = 146.499 kJ mol^{-1} from CODATA (13), we calculate the adopted value of $\Delta_f H°(Mg_2, g, 0)$ = 288.16 kJ mol^{-1}. Our adopted D° is in essential agreement with the value adopted by Brewer (12) and by Wagman et al. (3). It should be noted that a value of D_0^0 = 11.3 ± 4.1 kJ mol^{-1} was determined by a mass spectrometric study of Wu, Ihle and Gingerich (7). In light of the spectroscopic evidence, this value appears to be too large.

Heat Capacity and Entropy

The thermal functions are calculated using a direct summation technique analogous to the alkali dimers and diatomic halogens. Included in the calculation are the ground state and the three lowest excited states. Spectrocopic constants for the $^1\Sigma_g^+$ ground state are taken from an experimental study from Balfour and Douglas (1). No known spectroscopic data exists for the three lowest excited electronic states of Mg_2(g). In order to generate the spectroscopic constants of these states, a Morse potential was least squares fit to the calculated potential curves of Stevens and Krause (4), an ab initio investigation which included configuration interaction. Although this procedure for estimating the spectroscopic data results in substantial uncertainty in the generated constants, the inclusion of the excited states results in thermal functions which are more realistic at temperatures greater than 1000 K. The large maximum in the heat capacity at 5000 K, for example, would not be present if the excited states were not included. Also, it should be noted that Mg_2(g) is an example of a molecule where the traditional integration methods of calculating the thermal functions fail due to the shallow ground state.

The rotational levels are extrapolated to high J values according to the method of Khachkuruzov (5) who proposed a simpler form of Wooley's method (6). For the ground state only, we included the so-called quasi-bound rotational levels above the dissociation limit (9). The values used for J_{lim} and v_{max} are 93 and 17, respectively, as determined by (8). Separate calculations were performed for each of the six isotopic dimeric species (made up from the three atomic isotopes ^{24}Mg, ^{25}Mg, ^{26}Mg) by adjusting the spectroscopic constants of ^{24}Mg using a standard reduced mass scaling routine (10). The results were combined according to the natural abundance of the atoms, ^{24}Mg: 78.99%, ^{25}Mg: 10.00%, ^{26}Mg: 11.01% (11). Splitting of the rotational levels in the $^3\Pi_g$ and $^3\Sigma_u^+$ states was taken into account only insofar as the degeneracy of these states were increased accordingly. The adopted value of S°(298.15 K) is 0.64 J K^{-1} mol^{-1} smaller than that adopted by (8).

PREVIOUS: December 1974 (1 atm) CURRENT: September 1983 (1 bar)

$S°(298.15\ K) = 95.14 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2171 \pm 11\ K$

$\Delta_f H°(0\ K) = -2163.63 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2176.94 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [71.128 \pm 20.9]\ kJ\ mol^{-1}$

Enthalpy of Formation

Torgeson et al. (1) have reported a $\Delta_r H°(298.15\ K) = -15.1 \pm 0.2$ kcal mol^{-1} for reaction (a). They used an HF solution calorimeter and measured the enthalpies of solution of each component. We derive $\Delta_f H°(Mg_2SiO_4, cr, 298.15\ K) = -520.30 \pm 1.0$ kcal mol^{-1} using the $\Delta_f H°(298.15\ K)$ of MgO(cr) and SiO_2(cr, low quartz) from JANAF tables.

Kapustinskii et al. (2) used the same method but measured only $\Delta_r H°(298.15\ K) = 95.00 \pm 0.47$ kcal mol^{-1} for reaction (b). We calculate $\Delta_f H°(Mg_2SiO_4, cr, 298.15\ K) = -522.27$ kcal mol^{-1} using the $\Delta_f H°(298.15\ K)$ of H_2SiF_6(aq) from source 3 and the $\Delta_f H°(298.15\ K)$ of $H_2O(\ell)$ and HF(aq) from source 4.

Reesman et al. (5) calculated a $\Delta_r G°(298.15\ K) = 42.46$ kcal mol^{-1} for reaction (c) using aqueous solubility data. We use the $\Delta_f G°(298.15\ K)$ of $H_2O(\ell)$ and OH^-(aq) from source 4, $\Delta_f G°(298.15\ K)$ of H_4SiO_4(aq) from source 3 and $\Delta_f G°(298.15\ K)$ of Mg^{++}(aq) from source 6 and we obtain a $\Delta_f G°(Mg_2SiO_4, cr, 298.15\ K) = -498.764$ kcal mol^{-1}. We derive a $\Delta_f H°(Mg_2SiO_4, cr, 298.15\ K) = -524.848$ kcal mol^{-1} using the above $\Delta_f G°(298.15\ K)$ of Mg_2SiO_4(cr) and the entropies of Mg(cr), Si(cr) and O_2(g) from the JANAF tables.

The adopted value is from the work of Torgeson et al. (1) which is considered to be the most reliable since it relates *directly to the oxides. The other reported values are less accurate and involve uncertainties in the auxiliary data used to* derive the heat of formation.

Source	Method	Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f G°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53-295 K) of Kelley (7). High temperature enthalpies have been measured (398-1808 K) by Orr (8). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains *the curve to join smoothly with the low temperature values. The entropy is based on* $S°(50\ K) = 0.60$ cal $K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} *is obtained from Davis et al. (9).* $\Delta_{fus}H°$ *is estimated from MacGregor's (10) phase diagrams of the* $Mg_2SiO_4 - TiO_2$ system. The phase diagrams were determined at 10 and 20 kbars pressure.

PREVIOUS: September 1964 CURRENT: December 1967

MAGNESIUM SILICATE (Mg_2SiO_4) LIQUID M_r = 140.6931

$S°(298.15\ K) = [123.044]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2171 \pm 11\ K$

$\Delta_f H°(298.15\ K) = [-2113.88 \pm 20.9]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [71.128 \pm 20.9]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Mg_2SiO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Mg_2SiO_4, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(2171\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1400 K. Below 1400 K the heat capacity is obtained from the heat capacity of the crystal. Above 1400 K the heat capacity is assumed constant and estimated as 49 cal K^{-1} mol^{-1} or 7 cal K^{-1} $g\text{-}atom^{-1}$. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Enthalpy Reference Temperature = T_r = 298.15 K **Standard State Pressure = p° = 0.1 MPa**

MAGNESIUM TITANIUM OXIDE (Mg_2TiO_4) CRYSTAL M_r = 160.4876

$S°(298.15\ K) = 115.10 \pm 6.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2013 \pm 20\ K$

$\Delta_f H°(0\ K) = -2151.03 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2164.38 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [129.704]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from $\Delta_r H°(298.15\ K) = -4.1 \pm 0.25$ kcal mol^{-1} for the reaction 2 MgO(cr) + TiO_2(rutile) + Mg_2TiO_4(cr) measured by Kelley (1), using a solution calorimetric method. The uncertainty of ±1.5 kcal mol^{-1} assigned to the enthalpy of formation is due primarily to TiO_2(rutile).

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52 - 296 K) of Todd (2).

High temperature enthalpies have been measured (392 - 1817 K) by Orr (3). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values.

The entropy is based on S°(51 K) = 0.66 + 2.75 = 3.41 cal K^{-1} mol^{-1}, where the first term is a lattice contribution and the second term is a zero-point entropy of 2Rℓn2 corresponding to random distribution of Ti and Mg on the octahedral sites of the spinel lattice. *The adopted value is S°(298.15 K) = 27.51±1.5 cal K^{-1} mol^{-1} instead of 24.76±0.15 cal K^{-1} mol^{-1} as given by Todd.*

Barth (4) showed from intensities of the X-ray diffraction lines that Mg_2TiO_4 is a spinel of the inverse (or variate) class. Thus, half of the Mg ions occupy the tetrahedral interstices in the oxygen lattice, while the remaining Mg ions and the Ti ions are (presumably) randomly located in the octahedral interstices. This conclusion was confirmed by Romeijn (5).

King and Kelley (6) suggested that the degree of structural randomness is not established and that it may vary with the sample of Mg_2TiO_4; thus, they recommended an intermediate value of Rℓn2 for the zero-point entropy. In a previous review, however, Kelley (1) used the theoretical value of 2Rℓn2 in order to make Mg_2TiO_4 stable relative to $MgTiO_3$ at high temperatures. We choose to adopt 2Rℓn2, although the evidence is not conclusive. Recent studies of solid state reactions by Bautsch and Werner (7) indicate that $\Delta_r G°$ is negative for $MgTiO_3$(cr) + MgO(cr) + Mg_2TiO_4(cr) at temperatures of 1673 K and above. Both Rℓn2 and 2Rℓn2 are consistent with this evidence.

Fusion Data

See the liquid table for details.

PREVIOUS: June 1961 CURRENT: June 1967

$S°(298.15\ K)$ = [172.412] J K^{-1} mol^{-1}

T_{fus} = 2013 ± 20 K

$\Delta_f H°(298.15\ K)$ = [-2046.33 ± 6.3] kJ mol^{-1}

$\Delta_{fus} H°$ = [129.704] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Mg_2TiO_4, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Mg_2TiO_4, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(2013\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1400 K. Below 1400 K the heat capacity is obtained from the heat capacity of the crystal. Above 1400 K the heat capacity is assumed constant and estimated as 54.6 cal K^{-1} mol^{-1} or 7.8 cal K^{-1} g-atom^{-1}. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) suggested congruent melting at 2005 K. $\Delta_{fus} H°$ is estimated from those of $Na_2O{\cdot}2TiO_2$ and $Na_2O{\cdot}TiO_2$ observed by Naylor (3) and $CaO{\cdot}TiO_2{\cdot}SiO_2$ observed by King (4).

MAGNESIUM SILICIDE (Mg_2Si) CRYSTAL M_r = 76.6955

$S°(298.15\ K)$ = [81.588] J K^{-1} mol^{-1}

T_{fus} = 1375 K

$\Delta_f H°(298.15\ K)$ = [-77.822] kJ mol^{-1}

$\Delta_{fus} H°$ = [85.772] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ and T_{fus} from (1).

Heat Capacity and Entropy

$C_p°$ and $\Delta_{fus} H°$ from Kubaschewski and Evans (2). $S°(298.15\ K)$ estimated.

MAGNESIUM SILICIDE (Mg_2Si) LIQUID M_r = 76.6955

$S°(298.15\ K) = [123.472]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1375\ K$

$\Delta_f H°(298.15\ k) = [-3.327]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [85.772]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Mg_2Si, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Mg_2Si, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1375\ K)-H°(298.15\ K)$, between the crystal and liquid.

Fusion Data

T_{fus} from (1). $\Delta_{fus} H°$ from Kubaschewski and Evans (2). Other data estimated.

MAGNESIUM PHOSPHATE ($Mg_3P_2O_8$) CRYSTAL M_r = 262.85772

$S°(298.15\ K) = [188.280]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1621\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -3745.10 \pm 10.5\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [121.336 \pm 41.8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The selected $\Delta_f H°(298.15\ K)$ is a weighted average of a revised calorimetric determination and a 3rd law calculation using equilibrium data.

A calorimetric determination of the enthalpy of formation reported by Stevens and Turkdogan (1) was revised three ways:

1. The enthalpy of reaction for the reaction 3 MgO(cr) + P_2O_5(orthorhombic) → $Mg_3P_2O_8$(cr) had been evaluated at 348 K. A small temperature correction to 298.15 K was made with thermal data not available to Stevens and Turkdogan (1) on MgO (*Giauque* (2)), P_2O_5 *JANAF Table, Dec. 31, 1962*) and $Mg_3P_2O_8$ *(this table)*.
2. A new $\Delta_f H°(298.15\ K)$ for P_2O_5(hexagonal) as reported by Holmes (3) was combined with the enthalpy of reaction, -6.85 ± 1.0 kcal mol^{-1}, for the reaction: P_2O_5(hexagonal) → P_2O_5(orthorhombic) as reported by Hill et al. (4).
3. A correction of +8.35 kcal mol^{-1} was made for the change in phosphorus reference state from white (a) → red (V). (The correction is +8.35 kcal mol^{-1} of $Mg_3P_2O_8$ or +4.173 kcal mol^{-1} of P.)

This revised $\Delta_f H°(298.15\ K)$, -897.60±2.0 kcal mol^{-1}, would appear to be more reliable than the original value reported by Stevens and Turkdogan (1).

For the reaction $Mg_3P_2O_8$(cr) + 5 H_2(g) → 3 MgO(cr) + P_2(g) + 5 H_2O(g), the 3rd law treatment of the equilibrium data of Bookey (5) and the JANAF table free energy functions gave a $\Delta_f H°(298.15\ K)$ = -893.11 kcal mol^{-1}.

The quantity, -895.10±2.50 kcal mol^{-1}, is taken as the most probable value for the enthalpy of formation of magnesium orthophosphate.

Heat Capacity and Entropy

The entropy at 298.15 was estimated by considering the additive entropy constants of Kelley (6) and Evans and Kubaschewski (7). The heat capacity was estimated in a similar manner by considering the heat capacities of the constituent elements and related compounds such as Mg, O_2, MgO, P, P_2O_5, $Ca_2P_2O_7$, and $Ca_3P_2O_8$.

Fusion Data

The melting point, 1621 K, as reported by Stevens and Turkdogan (1) was selected. There is disagreement on the melting point in the literature. From the work of Winter (8), Kelley (9) has quoted a melting point of 1457 K and has calculated a "rather uncertain value" of 11.300 kcal mol^{-1} for the heat of fusion. Bookey (5) has found a melting point of 1703 K. Berak (10) gives 1630 K as the melting point.

Magnesium Phosphate ($Mg_3P_2O_8$) $Mg_3O_8P_2$(cr)

MAGNESIUM PHOSPHATE ($Mg_3P_2O_8$) LIQUID M_r = 262.85772

$S°(298.15\ K)$ = [235.102] J K^{-1} mol^{-1}

T_{fus} = 1621 K

$\Delta_f H°(298.15\ K)$ = [-3663.190] kJ mol^{-1}

$\Delta_{fus}H°$ = [121.336 ± 41.8] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Mg_3P_2O_8, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Mg_3P_2O_8, cr, 298.15\ K)$ by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1621\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity was estimated as 13/11 of the corresponding heat capacity of $Ca_2P_2O_7$ as given in Kelley (1). $S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The enthalpy of fusion was estimated by taking 13/11 of the $\Delta_{fus}H°$ of $Ca_2P_2O_7$ as given in Kelley (1).

Manganese (Mn) Mn_1(ref)

$S°(298.15\ K) = 32.01 \pm 0.08\ J\ K^{-1}\ mol^{-1}$
$T_{trs}(\alpha \rightarrow \beta) = 980 \pm 20\ K$
$T_{trs}(\beta \rightarrow \gamma) = 1361 \pm 10\ K$
$T_{trs}(\gamma \rightarrow \delta) = 1412 \pm 5\ K$
$T_{fus}(\delta \rightarrow \ell) = 1519 \pm 5\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{trs}H°(\alpha \rightarrow \beta) = 2.226 \pm 0.21\ kJ\ mol^{-1}$
$\Delta_{trs}H°(\beta \rightarrow \gamma) = 2.122 \pm 0.33\ kJ\ mol^{-1}$
$\Delta_{trs}H°(\gamma \rightarrow \delta) = 1.879 \pm 0.33\ kJ\ mol^{-1}$
$\Delta_{fus}H°(\delta \rightarrow \ell) = 12.058 \pm 1.0\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

A thorough re-examination of the manganese thermal functions is in process. Temporarily, the recommendations of Hultgren et al. (1) are adotped. These results are based on the heat capacity studies of Scurlock and Stevens (0.3-1.0 K, 2), Gaumer (0.84-3 K, 3), Guthrie et al. (1.7-4.2 K, 4), Booth et al. (12-20 K, 5), Kelley (52-298 K, 6), and Shomate (52-298 K, 7) and the enthalpy study of Naylor (373-1436 K, 8). As Hultgren et al. (1) states, the study of Naylor was chosen because it covers all forms of Mn in a self consistant manner. It is not stated why Hultgren, et al. (1) altered Naylor's equations (8), which appear more appropriate than the current values.

Phase and Fusion Data

As we are temporarily adopting the analysis of Hultgren, et al (1), we rely on his analysis of the transition and fusion temperatures. Ten studies are analyzed by Hultgren et al. (1). The temperatures were adjusted to IPTS-68.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: CURRENT: September 1967

$S°(298.15\ K) = [43.499]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1519 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [16.289]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 12.058 \pm 1.0\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Mn(ℓ), $\Delta_f H°(298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(1519 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Hultgren (1) adopted Cp°(ℓ) = 11.0 cal K^{-1} mol^{-1} based on the recommendation of Kelly (2). A glass transition temperature is assumed at 1125 K, below which the heat capacity values of α-Mn(cr) are adopted. a re-examination of Mn(ℓ) is in progress. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Vaporization Data

T_{vap}(1 bar) is calculated as the temperature at which $\Delta_r G° = 0$ for the process Mn(ℓ) = Mn(g). $\Delta_{vap} H°$ is calculated as the difference in the enthalpies of formation of Mn(ℓ) and Mn(g) at T_{vap}.

Manganese (Mn) $Mn_1(cr,l)$

MANGANESE (Mn) IDEAL GAS A_r = 54.9380

IP (Mn, g) = 59981 ± 1 cm^{-1}
$S°(298.15\ K)$ = 173.716 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 282.1 ± 4.2 kJ mol^{-1}
$\Delta_f H°$ = (298.15 K) = 283.3 ± 4.2 kJ mol^{-1}

Electronic Levels and Quantum Weights

State	ϵ_i, cm^{-1}	g_i
$^6S_{5/2}$	0.00	6
$^6D_{9/2}$	17052.29	10
$^6D_{7/2}$	17282.00	8
$^6D_{5/2}$	17451.52	6
$^6D_{3/2}$	17568.48	4
$^6D_{1/2}$	17637.15	2

Enthalpy of Formation

The value adopted for the enthalpy of formation of Mn(g), $\Delta_f H°(298.15\ K)$ = 283.3 ± 4.2 kJ mol^{-1}, is that recommended by Hultgren et al (1). This value is a weighted mean of sublimation and vaporization studies. The studies are: Bogatyrev and Golubtsov (1043-1168 K), 2), Pratt and Spencer (1248-1620 K, 3), Wiedemeier (1269-1448 K, 4), Butler et al. (1075-1335 K, 5), Woolf, et al. (1523-1823 K, 6), McCabe and Hudson (1075-1235 K, 7) and Baur and Brunner (1587-1987 K, 8).

A reanalysis of the vapor pressure data is in progress.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Corliss and Sugar (9), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only a few of the lowest lying levels for Mn(g), all levels listed by Corliss and Sugar (9), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for Mn(g), the thermodynamic functions are independent of the estimated missing levels (for n = 4-8), the cut-off procedure, and the inclusion of n<9 levels up to 4000 K; the Gibbs energy function showing no significant variations at this temperature. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>8), and use of different fill and cut-off procedures (10).

Enthalpy of Formation

$\Delta_f H°(Mn^+, g, 0\ K)$ is calculated from $\Delta_f H°(Mn, g, 0\ K)$ (1) using the spectroscopic value of $IP(Mn) = 59981 \pm 1\ cm^{-1}$ ($717.532 \pm 0.012\ mol^{-1}$) from Corliss and Sugar (2). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, $1\ cm^{-1} = 0.01196266\ kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Mn^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Mn, g, 0\ K)$ by using IP(Mn) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Mn(g), $Mn^+(g)$, and $e^-(g)$. $\Delta_f H°(Mn \rightarrow Mn^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by $-6.197\ kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Corliss and Sugar (2), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first two excited state, the highest observed excited state, and the ionization potential for $Mn^+(g)$, all levels listed by Corliss and Sugar (2), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $Mn^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=4-7), the cut-off procedure, and the inclusion of n<8 levels up to 6000 K; the Gibbs energy function showing, no significant at this temperature. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>7), and use of different fill and cut-off procedures (6).

$S°(298.15\ K) = 28.605 \pm 0.050\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2896 \pm 8\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 36.0 \pm 5.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities of Mo(cr) have been measured by Clusius and Franzosini (1) between 16 and 256 K (63 measured Cp points). The reported Cp values are smoothed by fitting the data with orthogonal polynomials over selected overlapping temperature intervals. This fitting procedure also includes the smoothed Cp° values (275-335 K) reported in the critical evaluation by Ditmars et al. (2) so as to provide smoothly varying heat capacity values in the range 256-275 K. The data of Simon and Zeidler (3), 15-238 K, are as much as 2.5% high below 78 K and as much as 1% low above 78 K.

Below 20 K several investigators (4, 5, 6, 7) have determined the heat capacity. Heiniger et al. (8) have summarized and critically reviewed this work as well as other studies. These sources give S°(20 K) values in the range 0.021-0.025 cal K^{-1} mol^{-1}. Adopting S°(20 K) = 0.024 cal K^{-1} mol^{-1} and combining this with our analysis of the Clusius and Franzosoni work (1), we calculate S°(298.15 K) = 6.836 ± 0.012 cal K^{-1} mol^{-1}. This result agrees with the review of the heat capacity data (T <298.15 K) by Reilly and Furukawa (9) for Brewer (10).

The high temperature heat capacity values, 273-2800 K, are those selected by Ditmars et al. (2). This study reports three recent NBS heat capacity/enthalpy studies covering the 270-2800 K on NBS Standard Reference Material No. 781. In addition, the report contains a bibliography of publications on the high temperature enthalpy and heat capacity of crystalline molybdenum. A graphical comparison of the NBS results with those of all the principal investigators and critical evaluation is also given in the publication. These results are linearly extrapolated from 2800 K to 3300 K. The high temperature heat capacity values adopted by Brewer (10), based on IPTS-48, are within 0.1% of the NBS results between 298 and 900 K and are 0.2 to 0.3% higher between 1000 and 1400 K. Between 1500 and 1900 K, the difference is less than 0.1%. From 2000 to 2300 K, the values are 0.2 to 0.3% lower and are 0.1% low to 0.2% high between 2400 to 2700 K. The value at 2800 K is 0.5% lower than our adopted value. At 2800 K, the entropy difference is 0.004 cal K^{-1} mol^{-1} with the JANAF value being smaller.

Fusion Data

Refer to the liquid table for details.

Sublimation Data

Eight sublimation studies are discussed on the ideal gas table.

PREVIOUS: December 1966 CURRENT: March 1978

$S°(298.15\ K) = [43.146]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2896 \pm 8\ K$

$\Delta_f H°(298.15\ K) = [41.568]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 36.0 \pm 5.4\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the crystal by addition of $\Delta_{fus}H°$ and the difference in enthalpy, H°(2896 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Enthalpy measurements via levitation calorimetry by Treverton and Margrave (3) were over a sufficient range of temperature, 2692-3112 K, to establish $Cp°(\ell) = 8.19\ cal\ K^{-1}\ mol^{-1}$. The enthalpy measurements of Berezin et al. (2) in the liquid region (14 pts., 2890-2925 K) are insufficient to define a liquid phase heat capacity value. Shaner et al. (5) and Dikhter and Lebedev (6) have reported $Cp°(\ell)$ values of 16.7 cal K^{-1} mol^{-1} and 14.0 cal K^{-1} mol^{-1}, respectively, using pulse heating techniques.

We adopt $Cp°(\ell) = 9.0\ cal\ K^{-1}\ mol^{-1}$ as did Brewer (9). This value implies a heavier weighting of the drop calorimetric studies rather than the pulse heating techniques. The magnitude of the difference of the $Cp°(\ell)$ values derived from the various studies (3, 5, 6) suggests further study in this area. A glass transition is assumed at 2150 K below which the heat capacity is assumed to be that of the crystal. The entropy is calculated in a manner analogous to the enthalpy of formation.

Fusion Data

The adopted melting point, $T_{fus} = 2896 \pm 8$ K, is derived from the recent experimental study and critical evaluation of earlier data by Kenisarin et al. (1).

Bererzin et al (2) have measured the enthalpy of crystal and liquid molybdenum by levitation calorimetry in the range 1962-2869 K and 2890-2925 K, respectively. They reported $\Delta_{fus}H° = 8.741 \pm 0.314\ kcal\ mol^{-1}$ at an assumed melting temperature of 2890 K. Correcting these results to $T_{fus} = 2896$ K yields $8.693 \pm 0.314\ kcal\ mol^{-1}$. Shaner et al. (5), using a pulse-heating technique, reported enthalpy measurements (1978-4450 K) which gave $\Delta_{fus}H° = 8.553\ kcal\ mol^{-1}$ at a melting point of 2883 K.

Treverton and Margrave (3) also used levitation calorimetry to measure the liquid phase enthalpy of molybdenum in the range 2693-3115 K. Using the enthalpy value for the liquid at the melting point as determined by Treverton and Margrave (3) and the enthalpy value of the crystal at the melting point as determined by our adopted functions, we calculate $\Delta_{fus}H° = 7.264$ kcal mol^{-1}. Lebedev et al. (7) reported $\Delta_{fus}H° = 9.864\ kcal\ mol^{-1}$ (exploding wire technique) while Kostekov et al. (8) found $\Delta_{fus}H° = 6.095\ kcal\ mol^{-1}$ (drop technique).

We adopt $\Delta_{fus}H° = 8.6 \pm 1.3\ kcal\ mol^{-1}$, which corresponds to $\Delta_{fus}S° = 2.97\ cal\ K^{-1}\ mol^{-1}$. This $\Delta_{fus}S°$ appears high for a metal with a bcc (A2) structure; however, this value is supported by the studies of Berezin et al. (2) and Shaner et al. (5). Brewer (9) selected a value of $\Delta_{fus}H° = 8.54 \pm 0.3\ kcal\ mol^{-1}$ (IPTS-48).

Vaporization Data

The boiling point and enthalpy of vaporization are calculated from the adopted functions and enthalpy of sublimation in order to maintain proper themodynamic consistency.

Koch and Anable (4) have measured the vapor pressure of liquid molybdenum by a Langmuir free-evaporation method. They measured 16 data points in the range 2895-2995 K. A 2nd and 3th law analysis gives $\Delta_{vap}H°(298.15\ K)$ values of 136.8 ± 18.4 and 147.7 ± 1.7 kcal mol^{-1}, respectively. This corresponds to our adopted value of $\Delta_{vap}H°(298.15\ K) = 147.565\ kcal\ mol^{-1}$. Note, however, that there is a significant difference between the 2nd and 3rd law results.

Enthalpy of Formation

The enthalpy of formation at 298.15 K for Mo(g) is simply the enthalpy of sublimation at 298.15 K; i.e. Mo(cr) → Mo(g). The following table summarizes the analysis of the numerous sublimation studies by a 2nd and 3rd law calculation. All temperatures have been corrected to IPTS-68. All studies are based on the Langmuir effusion method.

Source	Data Points	T/K	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}
1	eqn	1201-2396	159.8	158.5	-0.7
2	9	2068-2500	162.2±3.8	156.2±1.4	-2.6±1.6

5	eqn	1601-2297	131.7	148.8	8.8
6	12	2089-2493	156.8±1.6	156.9±0.6	0.1±0.7
7	10	2293-2673	152.4±4.1	158.2±1.4	2.3±1.6

A mass spectrometric study of the enthalpy of sublimation of molybdenum (8) yielded , $\Delta_{sub}H°(2500\ K)$ = 144.1±2.2 kcal mol^{-1}; correcting to 298.15 K, we calculate $\Delta_{sub}H°(298.15\ K)$ = 149.8 kcal mol^{-1}.

We adopt $\Delta_{sub}H°(298.15\ K)$ = 157.5±0.9 kcal mol^{-1} from a consideration of five studies (1, 2, 3, 6, 7). Brewer (12) has adopted a value 0.2 kcal mol^{-1} less positive; however his vapor pressure analysis is based on the 1948 temperature scale.

Heat Capacity and Entropy

The electronic energy levels are given in the compilations by Moore (9, 10). Although we have only listed the ground state, first excited state, highest observed excited state, and the ionization limit for Mo(g), all levels listed by Moore (9, 10), as well as estimated levels, are used in our calculations. The observed levels are too numerous to list completely. An examination of the estimates for missing levels suggests that they all lie above 20000 cm^{-1}. Our calculations indicate that for Mo(g) the thermochemical functions are independent of the estimated missing levels (for n = 5, 6, 7), the cut-off procedure, and the inclusion of n = 6, 7 levels up to 3000 K. The Gibbs energy function is essentially unaffected up to 4000 K. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic gas and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cut-off procedures (11). In fact, the inclusion of some higher states (n = 5, 6, 7) and consideration of various cut-off procedures leads to calculational differences in the Gibbs energy function of roughly 0.1 cal K^{-1} mol^{-1} or greater at temperatures in excess of 7600 K. The thermal functions adopted here are the same as those of Brewer (12).

Enthalpy of Formation

$\Delta_f H°(Mo^+, g, 0\ K)$ is calculated from $\Delta_f H°(Mo, g, 0\ K)$ (1) using the spectroscopic value of IP(Mo) = 57260 ± 50 cm^{-1} (684.982 ± 0.60 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Mo^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Mo, g, 0\ K)$ by using IP(Mo) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Mo(g), $Mo^+(g)$, and $e^-(g)$. $\Delta_f H°(Mo \rightarrow Mo^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first excited state, the highest observed excited state, and the ionization potential for $Mo^+(g)$, all levels listed by Moore, as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $Mo^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=4, 5), the cut-off procedure, and the inclusion of n=5 levels up to 4000 K; the Gibbs energy function showing variations of 0.4 J K^{-1} mol^{-1} at this temperature. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>5), and use of different fill and cut-off procedures (7).

MOLYBDENUM, ION (Mo^-) IDEAL GAS M_r = 95.94055

EA(Mo, g) = 0.746 ± 0.010 eV

$S°(298.15\ K)$ = 180.669 ± 0.003 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 585.390 ± 1.5 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [580.805] kJ mol^{-1}

Electonic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^6S_{5/2}$	0.0	6

Enthalpy of Formation

$\Delta_f H°(Mo^-, g, 0\ K)$ is calculated from $\Delta_f H°(Mo, g\ 0\ K)$ (1) using the adopted electron affinity of EA(Mo) = 0.746 ± 0.010 eV (71.978 ± 0.965 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Mo^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Mo^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Mo, g, 0\ K)$ by using EA(Mo) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Mo^-(g)$, Mo(g), and $e^-(g)$. $\Delta_r H°(Mo^- \rightarrow Mo + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Mo^-(g)$ is given by Hotop and Lineberger (2, 4) and Rosenstock et al. (5). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

Enthalpy of Formation

The enthalpy of formation of MoO(g) is taken from the critical analysis of the Mo-O system by Brewer (1). The adopted value is $\Delta_f H°(298.15\ K) = 74.32 \pm 8$ kcal mol^{-1}. All the current JANAF Thermochemical Tables for molybdenum-oxygen species are based on the internally consistent values of Brewer (1).

Choudary et al. (2) have reviewed earlier data and evaluations of $\Delta_f H°$ for MoO(g). They have also presented new data between 1462 and 1908 K. For the reaction 2 $MoO_2(g) = MoO(g) + MoO_3(g)$, the 3rd law values are mostly in the range -2.4 to -4.6 kcal mol^{-1} compared to 2nd law values of -7.8 kcal mol^{-1} or more negative. $\Delta_r H°/R = -2200 \pm 2000$ K was selected by Brewer (1) for the reaction as written.

Heat Capacity and Entropy

The ground state configuration is assumed to be similar to that for gaseous WO_3 (3). Swaminathan and Krisnamurthy (4) observed ten band systems which they attributed to molybdenum oxide with lower state values of $\omega_e = 950 \pm 10\ cm^{-1}$. Iorns and Stafford (5) also observed a band with a peak at 969 cm^{-1} in the vapor above MoO_3(cr). It is surprising that the observed vibrational frequency of MoO(g) is lower than 1055 cm^{-1} observed for WO(g). The latter comes not only from electronic spectra of the gas but also from infrared observation in matrix isolation; the former comes only from tentative assignments of electronic spectra presumably arising from MoO(g). It is possible that the observed states could be low lying excited states. We tentatively assume the fundamental vibrational frequency to be $1000 \pm 20\ cm^{-1}$. The anharmonicity correction x_e is estimated from the relation $x_e \mu^{1/2} = 0.014$ given by Barrow and Caunt (3). The constant (0.014) is assumed to be the same as that for WO(g). The value of α_e is calculated from the Morse potential function. Schroder (7) gave a relationship between bond order and Mo-O internuclear distance which yields values of 1.74 Å for a bond order of two and 1.62 Å for a bond order of three. A value 1.74±0.05 Å was used.

The suggestion of Hewett et al., (8) that the electronic structure of MoO should be closer to that of CrO than WO, was followed in using the same treatment as for MoF_2 (1) where g=3 was taken for the ground state and g=5 for a low-lying excited state at 450 cm^{-1}.

PREVIOUS: September 1978 (1 atm) CURRENT: September 1978 (1 bar)

Pearson Notation: mP12

$S°(298.15\ K) = 46.459 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -582.90 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -587.85 \pm 2.9\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation of MoO_2(cr) at 298.15 K is -140.5±0.2 kcal mol^{-1}. This value is chosen so as to be in agreement with Brewer (1) who has performed a critical analysis of all data pertaining to the molybdenum-oxygen system. However, Brewer (1) chose to adopt the value previously used by JANAF (14); a value which was derived as a weighted average of two calorimetric determinations and seven equilibrium studies, the latter results based on S°(298.15 K) = 11.954 cal K^{-1} mol^{-1}. In revising the S°(298.15 K) value to 11.04 cal K^{-1} mol^{-1} in this tabulation, the enthalpy of formation should also have been revised. With the exception of the data from Barbi (5) the following equilibrium studies suggest $\Delta_f H°$(298.15 K) = -141.20 kcal mol^{-1} in comparison with the calorimetric mean of $\Delta_f H°$(298.15 K) = -140.8 kcal mol^{-1} for MoO_2(cr). In addition, eight recent emf studies (published since the analysis by Brewer) also yield a value of $\Delta_f H°$(298.15 K) = -141.2 kcal mol^{-1}. Although there is some overlap in the values for $\Delta_f H°$ derived from equilibrium and calorimetric studies, the equilibrium studies appear to be more negative by 0.4 kcal mol^{-1}. Brewer (1) noted (in reference to $\Delta_f H°$(298.15 K) = -140.5 kcal mol^{-1}, however, that a better overall fit of all Mo-O data would be obtained if the enthalpy of formation of MoO_2(cr) were made more negative by 0.5 kcal mol^{-1} with a corresponding decrease of ~0.5 kcal mol^{-1} for MoO_2(g) and MoO(g) and ~0.8 kcal mol^{-1} for MoO_3 (g). Such a change could be accommodated in the MoO_2 tables.

Ignition of the bomb products from the calorimetric studies of Staskiewicz et al. (2) indicated that oxidation was only about 70 percent complete. The authors also digested the products with NH_4OH to remove the trioxide. The residue was the dioxide, as indicated by both oxidation and reduction. This evidence does not necessarily eliminate the possibility of known intermediate oxides in the combustion products. Mah (3) found 72-75 percent conversion to trioxide by weighing the total combustion products; no additional analysis was performed.

Reaction:
A. $MoO_2(cr) + 1/2\ O_2(g) = MoO_3(cr)$
B. $2\ Fe_xO(cr) + Mo(cr) = MoO_2(cr) + 2\ xFe(cr)$
C. $2\ NiO(cr) + Mo(cr) = MoO_2(cr) + 2\ Ni(cr)$
D. $Mo(cr) + 2\ CO_2(g) = MoO_2(cr) + 2\ CO(g)$
E. $Mo(cr) + 2\ H_2O(g) = MoO_2(cr) + 2\ H_2(g)$
F. $Mo(cr) + O_2(g) = MoO_2(cr)$ derived by the author from the cell reaction $2\ Fe_xO(cr) + Mo(cr) = MoO_2(cr) + 2\ xFe(cr)$ using $\Delta_f G°$ data for Fe_xO(cr)

Heat Capacity and Entropy

King (10) measured low temperature heat capacities from 53.3 to 296 K. King et al. (11) measured the high temperature enthalpy changes from 399 to 1801 K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that they join smoothly at 298.15 K. Deviations of the enthalpy data from the adopted values are -1.3 to +0.7%, excluding the point at 1801 K. This point at the highest temperature deviates by +2.3%, which suggests that the apparent heat capacity is rising very rapidly. No explanation for this rapid rise is available.

The entropy S°(298.15 K) = 11.104 cal K^{-1} mol^{-1} is obtained from the low temperature heat capacity data, based on S°(51 K) = 0.36 cal K^{-1} mol^{-1}. As discussed by Brewer (1), Ghose et al. (12) used neutron diffraction measurements to demonstrate the absence of a permanent magnetic moment. Thus no additional heat capacity or entropy contribution below 50 K due to a possible antiferromagnetic effect is necessary.

Enthalpy of Formation

The adopted enthalpy of formation for $MoO_2(g)$ at 298.15 K is -1.99±3 kcal mol^{-1}. This value was adopted by Brewer (1) who has performed a critical analysis of all data pertaining to the molybdenum-oxygen system. Brewer (1) adopted $\Delta_{sub}H°(298.15\ K)/R$ = 69700±1500 K for the sublimation process $MoO_2(cr) = MoO_2(g)$. The vapor pressures of MoO_2 calculated from the adopted tabulation slightly exceed those of Burns et al. (2) and are 50% lower than those of Chizhikov et al. (6). The adopted ΔG values for the formation of $MoO_2(g)$ from Mo(cr) and $O_2(g)$ average 1 kcal mol^{-1} more negative than those determined by Franklin and Stickney (7). The only recent determination that deviates seriously is that of Belton and Jordan (8) who determined the volatility of molybdenum in steam-hydrogen mixtures at 1200 and 1500°C. The variation of their results with water partial pressure at 1383 to 1500°C indicate an intercept corresponding to non-hydrated species which they attribute to MoO_3 and MoO_2. They assumed the ratio of MoO_2 to MoO_3 to be that observed by Burns et al. (2) and obtained partial pressures of MoO_2 about six times higher than calculated from the adopted values. Their values would require that $\Delta_f H°(298.15\ K)/R$ of $Mo(cr) + O_2(g) = MoO_2(g)$ be made more negative by 3200 K. If both $\Delta_{sub}H°$ and $\Delta_f H°(cr)$ were shifted by their assigned uncertainties indicated, a change of 2000 K could be accomodated.

Burns et al. (2) have investigated mass-spectrometrically the vapor in equilibrium with powdered $MoO_2(cr)$ and also reported the partial pressures of $MoO_2(g)$, $MoO_3(g)$, $(MoO_3)_2(g)$ and $(MoO_3)_3(g)$. DeMaria et al. (3) have measured the partial pressures of gaseous oxides MoO, MoO_2, and O(g) in the Mo-Al_2O_3 system by mass spectrometry. Blackburn et al. (4) and Plante (5) have studied the vapor pressures above MoO_2 (cr) by the Knudsen effusion method. More recently there have been mass spectroscopic Knudsen cell studies of Chizhikov et al. (6) of the vapor over $MoO_2(cr)$ between 1500 and 1730 K and the Langmuir type studies of Franklin and Stickney (7) on the vapor resulting from oxygen on a molybdenum surface.

Heat Capacity and Entropy

Hewett et al. (9) have reviewed the spectroscopic studies on $MoO_2(g)$. In addition they have studied spectroscopically MoO_2 in neon and argon matrices at 4 K. The adopted bond distance and angle and two stretching frequencies are derived from this study. Brewer (1) adopted the same values. The bending frequency (300 cm^{-1}) is estimated by comparison with other transition metal dioxides.

The electronic levels and quantum weights are estimated from the data reported by Weltner and McLeod (10) on WO_2. The ground state is assumed to be $^3A_1$ and the first excited level is assumed to lie close to the observed transitions at 7890 Å and 7806 Å in WO_2. Since both these states are presumed to be triplet, we have assigned a total degeneracy of 6. In addition, we expect from the electronic levels of $Mo^{+4}(g)$ (11) that other electronic states will also be found and these are arbitrarily estimated in the level at 25000 cm^{-1}. The principal moments of inertia are: $I_A = 3.3489 \times 10^{-39}$, $I_B = 11.4373 \times 10^{-39}$, and $I_C = 14.7862 \times 10^{-39}$ g cm^2.

Pearson Notation: mP60

$S°(298.15\ K) = [69.936 \pm 1.7]\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 875 \pm 50\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -708.41 \pm 3.3\ kJ\ mol^{-1}$

$\Delta_{trs} H° = [0]\ kJ\ mol^{-1}$

Enthalpy of Formation

For this oxide, the atomic ratio of oxygen to molybdenum is 2.750 or 11/4. The formula $MoO_{2.750}$ (upon which this tabulation is based) is more indicative of the oxygen content relative to MoO_2 and MoO_3, as opposed to Mo_4O_{11}. The thermochemical values describing $MoO_{2.750}$ are numerically 1/4 those of Mo_4O_{11}.

The high-temperature emf measurements (1, 2, 3) on compositions between MoO_2 and MoO_3 gave widely divergent results, some of which are contradicted by the Mo-O phase diagram recommended by Brewer (4). Brewer (4) found that it was more practical to determine a $\Delta_f H°(298.15\ K)$ value for $Mo_4O_{11}(cr)$ by fixing the thermodynamic properties from the peritectic equilibrium together with the thermodynamic data for the liquid. From the phase diagram (4), MoO_2 and Mo_4O_{11} solids are in equilibrium with the peritectic liquid of 74.2±0.1 atomic % oxygen at 1091±7 K. For $Mo_4O_{11}(cr) = MoO_2(cr) + 3\ MoO_3(\ell)$, Brewer (4) obtained $\Delta_r G°/RT$ = 0.863±0.05 at 1091 K. This yielded, using auxiliary data (5), $\Delta Hr°/R$ = 1280±400 K for the disproportionation of Mo_4O_{11} to crystalline MoO_2 and MoO_3 at 298.15 K. This heat of reaction yields $\Delta_r H°(298.15\ K)/R$ = -85203±200 K for Mo_4O_{11}, from which we calculate $\Delta_f H°(MoO_{2.750}, cr, 298.15\ K) = -169.315 \pm 0.4\ kcal\ mol^{-1}$. We increase the uncertainty in $\Delta_r H°$ to ±0.8 kcal mol^{-1} which better represents the effect of errors in reducing a $\Delta_r G°$ value at 1091 K to a $\Delta_f H°$ value at 298.15 K.

Heat Capacity and Entropy

Bousquet et al. (6) used differential enthalpy analysis to obtain enthalpies between 379 and 971 K for $Mo_4O_{11}(cr)$, $Mo_8O_{23}(cr)$, and $Mo_9O_{26}(cr)$. Brewer (1) compared their values of $MoO_2(cr)$ and $MoO_3(cr)$ mixtures with the same composition. For $Mo_4O_{11}(cr)$, the enthalpies were higher by 3% at 400 K, decreasing to 1.5% at 700 K. As these differences were within the scatter of the experimental measurements, Brewer (1) assumed $\Delta C_p° = 0$ and $\Delta S° = 0$ for the formation of Mo_4O_{11} from 3 $MoO_3(cr)$ and $MoO_2(cr)$.

Bousquet et al. (6) also measured the high temperature enthalpy data of MoO_3 fom 379 to 971 K. Their values agree with the adopted JANAF values for MoO_3 (5) within 2% below 500 K, but the deviations increase rapidly at higher temperatures becoming 10% high at 950 K. Thus, the adopted heat capacity values for $Mo_4O_{11}(cr)$, based on the assumption $\Delta C_p° = 0$ as discussed in the preceding paragraph, may be less reliable at higher temperatures.

Phase Data

Mo_4O_{11}(oP60) disproportionates to MoO_2 and liquid at 1091±7 K, according to the phase diagram of Phillips and Chang (7, 8). Mo_4O_{11}(oP60) transforms on cooling below 875±50 K to Mo_4O_{11}(mP60). Bousquet et al. (6) did not interpret their enthalpy data to include a transition at 875 K. However, a graphical examination of their data suggests two comments. First, the data point at 670 K may be a typographical error; perhaps 62.58 cal g^{-1} should be 52.58 cal g^{-1}. Second, a transition at approximately 850 K with a corresponding heat of ~0.7 kcal mol^{-1} could be easily derived. To be consistent with Brewer (4), we assume a transition at 875±50 K with a corresponding zero heat of transition.

In addition to the discussion of the molybdenum-oxygen system by Brewer (4), Gmelin Handbuch der Anorganischen Chemie (9) has recently presented a thorough summary of the literature dealing with the phase diagram and properties of the oxide phases. Ekstrom and Tilley (10) have reviewed the work of Ekstrom as well as the earlier work of Kihlborg (11) on the phases in the Mo-O system.

$S°(298.15\ K) = [73.849 \pm 1.7]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -727.13 \pm 2.5\ kJ\ mol^{-1}$

Enthalpy of Formation

For this oxide, the atomic ratio of oxygen to molybdenum is 2.875 or 23/8. The formula $MoO_{2.875}$ (upon which this tabulation is based) is more indicative of the oxygen content relative to MoO_2 and MoO_3, as opposed to Mo_8O_{23}. The thermochemical values describing $MoO_{2.875}$ are numerically 1/8 those of Mo_8O_{23}.

The high temperature emf measurements (1, 2, 3) on compositions between MoO_2 and MoO_3 gave widely divergent results, some of which are contradicted by the Mo-O phase diagram recommended by Brewer (4). Brewer (4) found that it was more practical to determine a $\Delta_f H°(298.15\ K)$ value for $MoO_{2.875}$ by fixing the thermodynamic properties from the peritectic equilibria together with the thermodynamic data for the liquid. From the Mo-O phase diagram (4), Mo_8O_{23} and Mo_4O_{11} solids are in equilibrium with the peritectic liquid of 74.45±0.1 atomic % oxygen at 1058±5 K. For the equilibrium $Mo_8O_{23}(cr) = Mo_4O_{11}(cr) + 4\ MoO_3(\ell)$, Brewer (4) calculated a $\Delta_r G°/RT$ value at 1058 K. This yielded, using auxiliary data (5), $\Delta_r H°/R$ = 380±200 K for the disproportionation of Mo_8O_{23} to crystalline Mo_4O_{11} and MoO_3 at 298.15 K. This enthalpy of reaction yields $\Delta_f H°(298.15\ K)/R$ = -87454±150 K from which we calculate $\Delta_f H°(MoO_{2.875}, cr, 298.15\ K) = -173.788 \pm 0.3\ kcal\ mol^{-1}$. We increase the uncertainty in $\Delta_f H°$ to ±0.6 kcal mol^{-1}; a value which better represents the effect of uncertainties in reducing a $\Delta_r G°$ value at 1058 K to a $\Delta_f H°$ value at 298.15 K.

Heat Capacity and Entropy

Bousquet et al. (6) used differential enthalpy analysis to obtain enthalpies between 379 and 971 K for $Mo_4O_{11}(cr)$, $Mo_8O_{23}(cr)$, and $Mo_9O_{26}(cr)$. Brewer (4) compared their values with values of $MoO_2(cr)$ and $MoO_3(cr)$ mixtures with the same composition. For $Mo_8O_{23}(cr)$, the enthalpies were lower by 15% at 400 K, lower by 3% at 500 K, and higher at higher temperatures, becoming 6% high at 700 K. As these differences were within the scalter of the expeirmental measurements, Brewer (4) assumed $\Delta C_p° = 0$ and $\Delta S° = 0$ for the formation of $Mo_4O(cr)$ from $3MoO_2(cr)$ and $MoO_2(cr)$.

Bousquet et al. (6) also measured high temperature enthalpy data of MoO_3 from 379 to 971 K. Their values agree with the adopted JANAF values (5) for $MoO_3(cr)$ within 2% below 500 K, but the deviations increase rapidly at higher temperatures becoming 10% high at 950 K. Thus, the adopted heat capacity values for $Mo_8O_{23}(cr)$, based on the assumption $\Delta C_p° = 0$ as discussed in the preceding paragraph, may be less reliable at higher temperatures.

Phase Data

The phase Mo_8O_{23}(mP62) was found by Kihlborg (7) and Bousquet and Guillon (8) at temperatures up to 1058-1063 K. Bousquet and Guillon (8) observed Mo_8O_{23} to disproportionate to $Mo_4O_{11}(cr)$ and $MoO_3(g)$ at 1053 K by differential thermal analysis. Brewer (4) adopted Mo_8O_{23} as a stable phase which disproportionates to Mo_4O_{11} and liquid at a temperature, T_{dec} = 1058±5 K, which is slightly above the disproportionation temperature of Mo_9O_{26}.

In addition to the discussion of the molybdenum-oxygen system by Brewer (4), Gmeli Handbuch der Anorganischen Chemie (9) has recently presented a thorough summary of the literature dealing with the phase diagram and properties of the oxide phases. Ekstrom and Tilley (10) have reviewed the work of Ekstrom as well as the earlier work of Kihlborg (11) on the phases in the Mo-O system.

MOLYBDENUM OXIDE ($MoO_{2.889}$) CRYSTAL M_r = 142.1623

Pearson Notation: mP70

$S°(298.15\ K) = [74.281 \pm 1.7]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -729.16 \pm 2.5\ kJ\ mol^{-1}$

Enthalpy of Formation

For this oxide, the atomic ratio of oxygen to molybdenum is 2.889 or, more exactly, 26/9. The formula $MoO_{2.889}$ (upon which this tabulation is based) is more indicative of the oxygen content relative to MoO_2 and MoO_3, as opposed to Mo_9O_{26}. The thermochemical values describing $MoO_{2.889}$ are numerically 1/9 those of Mo_9O_{26}.

The high temperature emf measurements (1, 2, 3) on compositions between MoO_2 and MoO_3 gave widely divergent results, some of which are contradicted by the Mo-O phase diagram recommended by Brewer (4). Brewer (4) found that it was more practical to determine a $\Delta_f H°(298.15\ K)$ value for $MoO_{2.889}$ by fixing the thermodynamic properties from the peritectic equilibria together with the thermodynamic data for the liquid. From the Mo-O phase diagram (4), Mo_9O_{26} and Mo_8O_{23} solids are in equilibrium with the peritectic liquid of 74.6±0.1 atomic % oxygen at 1053±5 K. *For the equilibrium* $Mo_9O_{26}(cr) = Mo_8O_{23}(cr) + MoO_3(t)$, Brewer (4) calculated a $\Delta_r G°/RT$ value at 1053 K. This yielded, using auxiliary data (5), $\Delta_r H°/R$ = 50±50 K for the disproportionation of Mo_9O_{26} to crystalline Mo_8O_{23} and MoO_3 at 298.15 K. This enthalpy of reaction yields $\Delta_f H°(298.15\ K)/R$ = -87699±150 K from which we calculate $\Delta_f H°(MoO_{2.889}, cr, 298.15\ K) = -174.275 \pm 0.3\ kcal\ mol^{-1}$. We increase the uncertainty in $\Delta_f H°$ to ±0.6 kcal mol^{-1}; a value which better represents the effects of uncertainties in reducing a $\Delta_r G°$ value of 1053 K to a $\Delta_f H°$ value at 298.15 K.

Heat Capacity and Entropy

Bousquet et al. (6) used differential enthalpy analysis to obtain enthalpies between 379 and 971 K for $Mo_4O_{11}(cr)$, $Mo_8O_{23}(cr)$, and $Mo_9O_{26}(cr)$. Brewer (4) compared their values with values of $MoO_2(cr)$ and $MoO_3(cr)$ mixtures with the same composition. For $Mo_9O_{26}(cr)$, the enthalpies were lower by 10% at 400 K but crossed over between 500 and 600 K and were 3% higher at 700 K. As these differences were within the scatter of the experimental measurements, Brewer (4) assumed $\Delta C_p° = 0$ and $\Delta S° = 0$ for the formation of $Mo_9O_{25}(cr)$ from $MoO_2(cr)$ and 8 $MoO_3(cr)$.

Bousquet et al. (6) also measured high temperature enthalpy data of MoO_3 from 379 to 971 K. Their values agree with the adopted JANAF values (5) for $MoO_3(cr)$ within 2% below 500 K, but the deviations increase rapidly at higher temperatures becoming 10% high at 950 K. Thus, the adopted heat capacity values for $Mo_9O_{26}(cr)$, based on the assumption $\Delta C_p° = 0$ as discussed in the preceding paragraph, may be less reliable at hgher temperatures.

Phase Data

Mo_9O_{26} (mP70) disproportionates at 1053±5 K to Mo_4O_{11} and liquid according to the phase diagram of Phillips and Chang (7, 8). Brewer (4) adopted a phase diagram which included Mo_8O_{23} which Phillips and Chang (7, 8) did not have.

In addition to the discussion of the molybdenum-oxygen system by Brewer (4), Gmelin Handbuch der Anorganischen Chemie (9) has recently presented a thorough summary of the literature dealing with the phase diagram and properties of the oxide phases. Ekstrom and Tilley (10) have reviewed the work of Ekstrom as well as the earlier work of Kihlborg (11) on the phases in the Mo-O system.

PREVIOUS: CURRENT: September 1978

Pearson Notation: oP16

$S°(298.15\ K) = 77.760 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1074 \pm 5\ K$

$\Delta_f H°(0\ K) = -740.15 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -745.17 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 48.534 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation, -178.1 kcal mol^{-1}, is the weighted average of two calorimetric determinations (1, 2). The result of these and other calorimetric determinations, all for the reaction $Mo(cr) + 3/2\ O_2(g) \rightarrow MoO_3(cr)$, are given below. Staskiewicz et al. (1) found that oxidation was only about 80% complete and tentatively attributed this to formation of $MoO_2(cr)$. Using their analytical results and their value of enthalpy of combustion for the dioxide, we obtain $\Delta_f H°(MoO_3, cr, 298.15\ K)$ = -177.98 kcal mol^{-1}. Subsequent discovery of oxides intermediate between MoO_2 and MoO_3 raises a possible uncertainty concerning the incomplete oxidation. Mah (2) also reported that combustion of the Mo(cr) sample ranged from 84 to 93 percent complete, as determined only by weight gain of the total combustion products upon prolonged low temperature ignition. In contrast, the earlier workers reported almost complete combustion. Neumann et al. (3) found about 97% completion using a wet analysis involving aqua regia. Moose and Parr (4) found that in several combustions, they obtained over 99% completion, based on the weight of the oxide formed.

Source	Year	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
(1)	1955	-177.98
(2)	1957	-178.16
(3)	1934	-180.4
(4)	1924	-175.6

Heat Capacity and Entropy

Smith et al. (5) measured low temperature heat capacities from 18.3 to 299.8 K. King et al. (6) measured high temperature enthalpy data from 399.3 to 1063.9 K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that they join smoothly near 300 K. Deviations of the enthalpy data from the adopted values are -0.65% to +0.17%. Seltz et al. (7) have also measured low temperature heat capacities from 70 to 298.7 K which are not in agreement with the values adopted; the discrepancy has been discussed by Smith. Cosgrove and Snyder (8) measured high temperture enthalpy data from 273 to 1068 K by drop calorimetry. Their smooth values are about 2% higher than the values adopted in the tabulation. Bousquet et al. (9) also measured high temperature enthalpy data from 379 to 971 K. Their values agree with the adopted values within 2% below 500 K, but the deviations increase rapidly at higher temperature becoming +10% at 950 K.

The entropy, $S°(298.15\ K)$ = 18.585 cal K^{-1} mol^{-1}, is obtained from the low temperature heat capacity data of Smith et al. (5), based on $S°(20\ K)$ = 0.197 cal K^{-1} mol^{-1}. This starting entropy was obtained by the authors from a T^3 extrapolation of the data. Recently, McBride and Westrum (10) have shown that the T^2 limiting law is inappropriate for MoS_2 and a T^3 law is suggested for this and other compounds with lamellar lattices. They have also shown that the heat capacity data of Smith et al. for MoS_2 (5) was positively biased by 0.07 cal K^{-1} mol^{-1} below 100 K. If the same bias is present in the $C_p°$ data of Smith et al. for MoO_3, and a T^3 extrapolation is used, our analysis suggests a reduction of ~0.12 cal K^{-1} mol^{-1} in $S°(298.15\ K)$. Other treatments result in estimated decreases in $S°(298.15\ K)$ ranging from 0.08 to 0.17 cal K^{-1} mol^{-1}. The increasing scatter in the $C_p°$ data below 40 K (indicative of a loss of calorimeter sensitivity) coupled with uncertainty due to bias suggests an uncertainty of ±0.3 cal K^{-1} mol^{-1} for $S°(298.15\ K)$. Therefore, we adopt the author's original interpretation while recognizing the need for new low temperature $C_p°$ measurements. It is surprising that the entropy of $MoO_3(cr)$ is larger than that of $WO_3(cr)$ by about 0.4 cal K^{-1} mol^{-1}. This may be due to the difference in the crystal structures, MoO_3 being orthorhombic (oP16) and WO_3 monoclinic, and also to uncertainty in the entropy extrapolation below 50 K for $WO_3(cr)$.

Fusion Data

The adopted melting point, 1074 ± 5 K, is obtained from King et al. (6). The enthalpy of fusion is calculated from the adopted enthalpies of the crystal and liquid based on the enthalpy data of King. Cosgrove and Snyder (8) found the melting point 1068 K by the cooling curve method and derived $\Delta_{fus} H°$ = 12.54 kcal mol^{-1} from their smooth enthalpy values at the melting point.

PREVIOUS: June 1967 CURRENT: September 1978

$S°(298.15\ K) = [114.935]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1074 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-703.727]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 48.534 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(MoO_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus}H°$, and the difference in enthalpy, $H°(1074\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived from the enthalpy data (1074 - 1392 K) measured by King et al. (1). The heat capacity is assumed constant above and below the measured range. At 750 K, a glass transition is assumed, below which the heat capacity is taken to be the same as that of the crystal. $S°(MoO_3, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Cosgrove and Snyder (2) also measured enthalpy data for $MoO_3(\ell)$ in the temperature range from 1068 to 1300 K. Their smooth values are 2.5 to 4.0 percent higher than our tabulated values.

Fusion Data

See the crystal table for details.

Vaporization Data

Effusion (3) and transpiration (4) measurements indicate that $MoO_3(g)$ is not the major species found in the vapor above MoO_3 condensed phases. Both sets of measurements indicate the presence of polymeric species $(MoO_3)_x$ where the predominant species near the normal boiling point are those for x=3 and 4. At higher temperatures the equilibrium shifts toward lower x but $MoO_3(\ell)$ will reach 1 atm at 1380±30 K based primarily on the transpiration measurements of Ackermann et al. (4). Feiser (6), using indirect methods, reported a normal boiling point of 1438 K. We adopt Brewer's estimate (5) and emphasize that this represents vaporization to a mixture of gases, $(MoO_3)_x$.

Ground State Quantum Weight: [1] σ = 3
Point Group: C_{3v}
Bond Distance: Mo-O = [1.73] Å
Bond Angle: O-Mo-O = 99°
Product of the Moments of Inertia: $I_A I_B I_C$ = [3.0307222 x 10^{-114}] g^3 cm^6

Enthalpy of Formation

Burns et al. (1) determined the partial pressures of gaseous oxides MoO_2, MoO_3, $(MoO_3)_2$ and $(MoO_3)_3$ in equilibrium with powdered MoO_2 by mass spectrometry. Plante (2), Blackburn et al. (3) and Chizhikov et al. (4) also investigated the vapor pressures above molybdenum dioxide by the Knudsen effusion method. These studies (1-4) involve the disproportionation of MoO_2(cr) to Mo(cr) and MoO_3(g). DeMaria et al. (5) reported the partial pressures of MoO(g), MoO_2(g), MoO_3(g) and O(g) in the Mo-Al_2O_2 system from mass spectrometry.

The selected enthalpy of formation is -82.8 kcal mol^{-1}, based on the 3rd law value of $\Delta_f H°(298.15\ K)$ of Burns et al. (1). The choice is made because there is serious doubt about the data of Blackburn (3) as discussed by Burns et al. (1). In addition, the assumption made by Plante (2) that they only vapor species of any importance is MoO_3 may be erroneous. The mass specrometric work of Burns et al. (1) is thus preferred. Our adopted value differs slightly from the value of -82.57 kcal mol^{-1} adopted by Brewer (7), which is also based on Burns et al. (1). The difference is a result of slight differences in Gibbs energy functions in the respective auxiliary data for Mo(cr) (6, 7).

The heat of atomization calculated from the JANAF tables (6) is $\Delta_{at}H°(0\ K)$ = 415.9±5.1 kcal mol^{-1}.

Heat Capacity and Entropy

In a recent IR matrix isolation study, Hewett et al. (8) observed peaks at 976 and 922 cm^{-1} which they assigned to stretching modes of MoO_3(g). We add 2 cm^{-1} to these frequencies to correct for the matrix effect. The observation of two stretching modes in the infrared spectrum suggests a pyramidal C_{3v} structure for MoO_3(g). Hewett et al. performed a normal coordinate analysis using a bond distance of 1.8 Å and an estimated bending force constant (f_α) of 0.296 mdyn/Å. Variations of 20% in f_α changed the calculated stretching frequencies by only a few cm^{-1}. The calculated stretching frequencies were more sensitive to the estimated pyramidal angle (β) which was adjusted to obtain the best fit to the observed stretching frequencies of oxide molecules containing ^{16}O, ^{18}O, and mixed ^{16}O-^{18}O. The final results yielded β = 61.5±2° and values of 261, 275 and 275 cm^{-1} for the bending frequencies of $Mo^{16}O_3$. Due to the insensitivity of the normal coordinate analysis to f_α these bending frequencies are useful only for comparing changes due to isotopic substitution. In contrast, we adopt bending frequencies of 310, 310 and 340 cm^{-1} and a bond distance of 1.73 Å as selected by Brewer (7) for consistency with other metal oxides. The pyramidal angle of 61.5° is adopted; the possible effect of using a shorter bond distance during the normal coordinate analysis is unknown. The pyramidal angle of 61.5° corresponds to an O-Mo-O bond angle of 99°. Based on the adopted structure, the principal moments of inertia are I_A=I_B=[12.8372 x 10^{-39}] and I_C=[18.3909 x 10^{-39}] g cm^2. The thermochemical functions are consistent with those of Brewer (7).

PREVIOUS: September 1978 (1 atm) CURRENT: September 1978 (1 bar)

MOLYBDENUM SULFIDE (MoS_2) CRYSTAL M_r = 160.06

Pearson Notation: hP6

$S°(298.15\ K) = 62.572 \pm 0.08\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2023 \pm 50\ K\ [p = 1\ atm\ S_2(g)]$

$\Delta_f H°(0\ K) = -273.31 \pm 2.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -276.14 \pm 2.5\ kJ\ mol^{-1}$

$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The adopted enthalpy of formation is from Brewer (1) and is a weighted average of calorimetric (2) and equilibrium (3) values. O'Hare et al. (2) obtained $\Delta_f H°(298.15\ K) = -65.8 \pm 1.2\ kcal\ mol^{-1}$ using a fluorine bomb calorimeter. Larson and Elliott (3) studied the equilibrium $MoO_2(cr) + 2\ SO_2(g) = MoS_2(cr) + 3\ O_2(g)$ via emf technique (1051-1372 K); using auxiliary data (1, 4) Brewer calculated $\Delta_f H°(MoS_2, 298.15\ K) = -66.64 \pm 0.6\ kcal\ mol^{-1}$ from their results. Thermodynamic analysis of other calorimetric and equilibrium measurements (5-7) are summarized by O'Hare et al. (2) and Mills (8).

Heat Capacity and Entropy

The adopted values of $C_p°$ are from Brewer (1) and are based on experimental $C_p°$ data (6-346 K) of McBride and Westrum (9) and high temperature enthalpy data (523-1204 K) of Fredrickson and Chasanov (10). $C_p°$ values above 1200 K are extrapolated. The recent enthalpy data (500-1700 K) of Volovik et al. (11) agrees with enthalpies in this table to within ±2% to 2000 K. Older $C_p°$ data of Smith et al. (12) and Anderson (13) contain considerable scatter and are given no weight.

$S°(298.15\ K)$ is obtained from the appropriate integration of the adopted $C_p°$ data based on $S°(10\ K) = 0.012\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

The crystal structure of MoS_2 is (hP6). Mering and Levialdi (14) have shown that nonstoichiometric sulfur-rich modifications (which have essentially the hP6 structure with expansion and distortion of the lattice) can be prepared as metastable compositions up to $MoS_{2.59}$; amorphous metastable phases are obtained with higher sulfur contents. For information on other metastable phases, see (1) and (15). According to Brewer's (1) phase diagram the compositional range of stability decreases as the temperature increases.

Based on Cannon's evidence (16) of a melting point in excess of 2073 K, Brewer (1) adopted a congruent melting point of 2173 K. However, congruent melting is observed only at high sulfur pressures; the melting point of 2173 K corresponds to a $S_2(g)$ pressure of ~4 atm. Incongruent melting points up to 350 K lower may be obtained depending upon the pressure of $S_2(g)$. The adopted melting point is that selected by Brewer (1) for an $S_2(g)$ pressure of 1 atm. Mills (8) adopted a 1 atm value of 1458 K which appears much too low.

MOLYBDENUM SULFIDE (Mo_2S_3) CRYSTAL M_r = 288.06

Pearson notation: mP10

$S°(298.15\ K) = 114.976 \pm 8.4\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2080 \pm 20\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -407.103 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = -129.704 \pm 41.8\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation is taken from the critical review by Brewer (1). His linear regression analysis of equilibrium data, which is based on Cubicciotti's sigma-plot method (2), yields both $\Delta_f H°(298.15\ K)$ and $S°(298.15\ K)$. The data used in Brewer's analysis are outlined below. Auxiliary data are taken from the JANAF tables (3).

Source	Reaction	T/K
McCabe (4)	A	1303 - 1425
Isakova (5)	B	1523 - 1738
Hager and Elliott (6)	C	1366 - 1612
Stubbles and Richardson (7)	C	1119 - 1467
Pouillard and Perrot (8)	C	1030 - 1280
Stubbles and Richardson (7)	D	1270 - 1470
Pouillard and Perrot (8)	D	1030 - 1280

Reactions:

(A) $2\ Mo(cr) + 3/2\ S_2(g) = Mo_2S_3(cr)$

(B) $2\ MoS_2(cr) = Mo_2S_3(cr) + 1/2 S_2(g)$

(C) $2\ Mo(cr) + 3\ H_2S(g) = Mo_2S_3(cr) + 3\ H_2(g)$

(D) $2\ MoS_2(cr) + H_2(g) = Mo_2S_3(cr) + H_2S(g)$

Heat Capacity and Entropy

There are no experimental high temperature heat capacity or enthalpy studies. The adopted heat capacity, which is assumed to represent the high temperature crystal form, is based on the estimate of Gronvold and Westrum (9), $C_p° = 26.36 + 7.88 \times 10^{-3}T = 2.30 \times 10^5/T^2$. The value of $S°(298.15\ K)$ is taken from Brewer (1), see above.

Rastogi and Ray (10) measured the low temperature $C_p°$ (80-350 K) but report only $C_p°(298.15\ K) = 33.2\ cal\ K^{-1}\ mol^{-1}$. This value apparently refers to the low temperature superstructure crystal form but is not expected to differ significantly from the high temperature form. The reason for the 7 cal K^{-1} mol^{-1} discrepancy between the Rastogi-Ray value of $C_p°(298.15\ K)$ and that adopted here is not known but it should be mentioned that the Rastogi-Ray value is well above the classical limit of 15R. Insufficient information on sample preparation and calorimetric technique is available to assess the validity of the Rastogi-Ray data.

Phase Data

The crystal structure of Mo_2S_3 is monoclinic and belongs to space group $P2_1/m$ above 310 K (11). Below 310 K all axes are doubled and a superstructure is formed. The heat of transition is reported to be 5 cal K^{-1} mol^{-1} (10).

The stability region for Mo_2S_3 is from 900±40 K (1) to the melting point. Below 900 K the material is metastable with respect to disproportionation to Mo(cr) and MoS_2(cr). However equilibrium is established very slowly below 1100 K (11, 12) and, once prepared, Mo_2S_3 may be quenched and stored indefinitely at room temperature. The enthalpy of decomposition at 900 K ($\Delta_{dcm}H°$) for the reaction $Mo_2S_3(cr) + 1/2\ Mo(cr) + 3/2\ MoS_2(cr)$ is calculated from the JANAF tables (3).

Fusion Data

We adopt the congruent melting point from Brewer (1). The enthalpy of fusion is estimated assuming an entropy of fusion of ~3 cal K^{-1} g-atom^{-1} as suggested by Kubaschewski et al. (13). This gives a enthalpy of fusion of 31 kcal mol^{-1} and the uncertainty is estimated to be 10 kcal mol^{-1}.

MOLYBDENUM SULFIDE (Mo_2S_3) LIQUID M_r = 288.06

$S°(298.15\ K) = [181.170]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2080 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [-270.304]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 129.704 \pm 41.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Mo_2S_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy fusion, of $\Delta_{fus}H°$, and the difference in enthalpy, $H°(2080\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A constant liquid $C_p°$ of 7.5 cal K^{-1} g-atom^{-1} is assumed which yields a $C_p°$ value of 37.5 cal K^{-1} mol^{-1}. This value is adopted above an assumed glass transition at 1450 K. The heat capacity of the crystal (1) is assumed below the glass transition.

$S°(Mo_2S_3, \ell, 298.15\ K)$ is calculated by a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details (1).

Decomposition Data

According to Brewer's phase diagram (2), Mo_2S_3 has a very short liquid range at 1 atm $S_2(g)$. We adopt a decomposition temperature of 2140±30 K based on the phase diagram (2). Above this temperature $Mo_2S_3(\ell)$ decomposes to $S_2(g)$ plus a liquid poorer in sulfur than Mo_2S_3. At higher sulfur pressures, the liquid range is much more extensive.

MOLYBDENUM SULFIDE (Mo_2S_3) CRYSTAL-LIQUID M_r = 288.06

298 to 2080 K* crystal
above 2080 K liquid

Refer to the individual tables for details.

*This material is reported to be metastable with respect to disproportionation to Mo(cr) and MoS_2(cr) below ~900 K. However, disproportionation is very slow and the material may be quenched and stored at room temperature indefinitely.

Enthalpy Reference Temperature = T_r = *298.15 K* *Standard State Pressure* = $p°$ = *0.1 MPa*

$S°(298.15\ K) = 26.712 \pm 0.042\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -130.187 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -132.214 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

Pankratz et al. (1) measured the enthalpy of combustion of vanadium subnitride at 303.15 K. The composition of their sample was $VN_{0.465}$ which corresponds to the nitrogen-rich boundary of the subnitride phase (see Phase Data section). Chemical analysis also showed that the sample contained 0.74 weight percent VO and trace amounts of CaO and Mo as impurities. The composition of the combustion products fell between V_2O_4 and V_2O_5. JANAF data (2) for these two oxides are used to correct their combustion values to correspond to the formation of the pentoxide as the final state. Our values for this correction are roughly 3 cal K^{-1} mol^{-1} subnitride greater than those used by Pankratz et al. (1). Impurity corrections for VO and Mo are also based on JANAF (2) data and amount to 9.03 and 0.37 cal g^{-1} subnitride, respectively. For the process $VN_{0.465}(cr) + 1.25\ O_2(g) = 0.5\ V_2O_5(cr) + 0.2325\ N_2(g)$, we obtain $\Delta_c H° = -153.69 \pm 0.75$ kcal mol^{-1} at unit fugacities of oxygen and nitrogen. When this value is combined with $\Delta_f H°(V_2O_5, cr, 298.15\ K)$ (2), that for vanadium subnitride is $\Delta_f H°(VN_{0.465}, cr, 298.15\ K) = -31.6 \pm 1.5$ kcal mol^{-1}. We adopt this value and include in the overall uncertainty (±1.5 kcal mol^{-1}) the error associated with correcting the combustion values to correspond to the pentoxide as the final state. *The only other value for $\Delta_f H°$ is derived from dissociation pressure data for* $VN_{0.43}$ which were reported by Brauer and Schnell (3) for the temperature range 1655-1879 K (corrected to IPTS-68). JANAF functions for $VN_{0.465}$ are used to analyze these pressures by the 3rd law method. These calculations lead to $\Delta_f H°$ for the subnitride phase of -25.2 ± 1.7 kcal mol^{-1}. The 2nd law value is $\Delta_f H°(298.15\ K) = -10.7$ kcal mol^{-1}; the 3rd law drift is 8.3 ± 1.1 cal K^{-1} mol^{-1}. These results show considerable scatter and are believed to be less reliable than those obtained by combustion calorimetry.

Heat Capacity and Entropy

Pankratz et al. (1) have measured low temperature heat capacities (9 to 307 K) for $VN_{0.465}$ in an adiabatic calorimeter. The composition of the subnitride sample was similar to that employed in their combustion work. Their $C_p°$ data are adopted and used to obtain a value (6.384 cal K^{-1} mol^{-1}) for S°(298.15 K). This latter value is based on S°(9 K) = 0.004 cal K^{-1} mol^{-1}.

In the same paper, Pankratz et al. (1) reported measurements of the high temperature enthalpies (401-1794 K) for $VN_{0.465}$ which were obtained in a copper-block drop calorimeter. The subnitride sample was the same as that used in their combustion work and was contained in Pt-Rh alloy capsules during the "drop" experiments. Temperature measurements were based on the IPTS-68 scale. A technique employing orthogonal polynomials is used to fit their experimental enthalpies by computer. The curve is constrained to join smoothly with the low temperature $C_p°$ data near 298.15 K. The average deviation of the smoothed enthalpies from the experimental values is +0.46%; the maximum deviation is +0.73% at 702 K. $C_p°$ data above 1800 K are obtained by graphical extrapolation. No anomalies are observed in either the low temperature $C_p°$ data or the high temperature enthalpies.

Phase Data

In a review of vanadium binary systems, Rostoker and Yamamoto (4) have questioned the existence of a subnitride phase, since Muthmann et al. (5) were unable to recognize its presence. However, several recent investigations (1, 3, 6-8) have reported the preparation of the subnitride at temperatures in excess of 1300 K. Using x-ray techniques, Brauer and Schnell (3) and Hahn (6) found that the phase had an extensive homogeneity range which extends from about $VN_{0.37}$ to $VN_{0.49}$ (27 to 33 atomic percent nitrogen). Pankratz et al. (1) reported the composition of the nitrogen-rich phase boundary as $VN_{0.465}$. These results are in agreement with the earlier x-ray work (3, 6). The structure of vanadium subnitride has been determined to be hexagonal (6, 7). Further information on the vanadium-vanadium nitride system has been reviewed by Storms (9).

Decomposition Data

No information is available on the melting behavior of $VN_{0.465}$ at elevated temperatures. Mass spectrometric evidence (10) has been presented which indicates that vanadium mononitride decomposes to its elements rather than melting. By analogy with VN, *we assume the process $VN_{0.465}(cr) = V(\ell) + 0.2325\ N_2(g)$ to be the mode of decomposition upon heating the solid.* T_{dcm} = 2875 K is the temperature at which the fugacity for the above process approaches 1 atm. $\Delta_{dcm}H°$ = 34.3 kcal mol^{-1} is the negative of the enthalpy of formation of $VN_{0.465}$ at T_{dcm}.

Enthalpy of Formation

$\Delta_f H°$ is based on the D_0^0 value for $N_2(g)$ adopted by the Committee on Data for Science and Technology (CODATA) of the International Council of Scientific Unions (1). The adopted value for $\Delta_f H°(N, 298.15, 0\ K)$ is derived using $D_0^0(N_2, g) = 78715 \pm 50\ cm^{-1}$ (225.057 ± 0.143 kcal mol^{-1}) from Buttenbender and Herzberg (2), Tanaka, Ogawa, and Jursa (3), and Telford, Vanderslice, and Wilkinson (4). This is discussed further by Gaydon(5) and Lofthus and Krupenie (6).

Heat Capacity and Entropy

The electronic levels for N(g) are given in the compilation by Moore (7). Our calculations indicate that, except for the five states lying below 29000 cm^{-1}, the inclusion of levels up to n = 12 has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of these levels; the fifth excited state lies at 83284.070 cm^{-1} above the ground state. Since the inclusion of these upper levels has no effect on the thermodynamic function (to 6000 K) we list only the lowest lying states (ϵ_i < 29000 cm^{-1}). The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cut off procedures (8).

PREVIOUS: March 1977 (1 atm) CURRENT: December 1982 (1 bar)

$IP(N^+, g) = 238750.50 \pm 1.3\ cm^{-1}$

$S°(298.15\ K) = 159.797 \pm 0.02\ JK^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1873.152 \pm 0.42\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [1882.130]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i cm^{-1}	g_i
$^3P_0$	0	1
$^3P_1$	48.7	3
$^3P_2$	130.8	5
$^1D_2$	15316.2	5
$^1S_0$	32688.8	1
$^5S_2$	46784.6	5

Enthalpy of Formation

$\Delta_f H°(N^+, g, 0\ K)$ is calculated from $\Delta_f H°(N, g, 0\ K)$ (1) using the spectroscopic value of IP(N) = 117225.7 ± 0.3 cm^{-1} (1402.331 ± 0.004 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(N^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(N, g, 0\ K)$ by using IP(N) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for N(g), $N^+(g)$, and $e^-(g)$. $\Delta_f H°(N \rightarrow N^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (6) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first five excited states; the next excited state is 92237.2 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first five excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (6).

NITROGEN, ION (N^-) IDEAL GAS M_r = 14.00725

EA(N, g) = -0.07 ± 0.02 eV

$S°(298.15\ K)$ = 159.927 ± 0.001 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 477.574 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [473.540] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^3P_2$	0.0	5
$^3P_1$	[63]	3
$^3P_0$	[90]	1
$^1D_2$	[10800]	5
$^1S_0$	[22390]	1

Enthalpy of Formation

$\Delta_f H°(N^-, g, 0\ K)$ is calculated from $\Delta_f H°(N, g, 0\ K)$ (1) using the adopted electron affinity of EA(N) = -0.07 ± 0.02 eV (-6.754 ± 1.930 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a dissociative attachment of electrons study (3). Additional information on $N^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(N^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(N, g, 0\ K)$ by using EA(N) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $N^-(g)$, N(g), and $e^-(g)$. $\Delta_r H°(N^- + N + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state for $N^-(g)$ is reported to be $2p^4\ ^3P$. We estimate the fine structure separations in the ground state by comparison of isoelectronic series based on $N^-(g)$ [N^-, O, F^+, Ne^{++}, Na^{+++}] and C(g) [C, N^+, O^{++}, F^{+++}]. The unceratainty in $S°(298.15\ K)$ in part reflects this estimation. Massey (6) listed the hyperfine splitting of the ground state as 97 and 137 cm^{-1} based on a quadratic isoelectronic extrapolation. This technique led to high values in the case of $O^-(g)$ (5) and is assumed to give high results for $N^-(g)$.

A comparison of the isoelectronic sequence - $N^-(g)$, O(g), $F^+(g)$ - would suggest that stable electronic states may exist at low wave numbers. These states would greatly affect the entropy. We estimate two of these levels.

Enthalpy of Formation

Herzberg (1), lists two D_0^0(NO) values, 5.296 and 6.487 eV. Gaydon (2) lists D_0^0(NO) = 6.49±0.05 eV. A Birge-Sponer extrapolation of the vibrational levels, up to v = 18, of the ground state leads to a D_0^0 of about 6.5 eV. Gaydon's (2) analysis on the predissociation of NO also leads to the higher value for D°(NO).

Tanaka (3), has observed and analyzed the emmission bands of NO in the vacuum ultraviolet region. Tanaka's (3), observation and interpretation of the abrupt cutoff (predissociation) of certain v' values in the β, γ, and δ bands and of the complete non appearance of ε and β' bands strongly favors a D°(NO) = 6.48 eV. $\Delta_f H°$(NO, g, 298.15 K) was calculated on this basis to be 22.033±1 kcal mol^{-1}.

More recently Frisch (4), has calorimetrically determined the enthalpy of reaction for:

$$NO(g) + CO(g) \rightarrow CO_2(g) + 1/2N_2(g)$$

at 298.15 K, from which the author derives a $\Delta_f H°$(NO, g, 298.15 K) = 21.58±0.04 kcal mol^{-1}. The auxiliary values used by Frisch to calculate the enthalpy of formation of nitric oxide were based upon the 1961 atomic weight scale. Recalculating $\Delta_f H°$(NO, g, 298.15 K) using auxiliary functions based on the 1956 atomic weight scale had a negligible effect on the final result.

The calorimetrically determined heat of formation for nitric oxide, 21.58±0.04 kcal mol^{-1}, was selected as the best value.

Heat Capacity and Entropy

The spectroscopic constants were taken from Gillette and Eyster (5), who measured and analyzed the fundamental rotation-vibration band of nitric oxide using a grating spectrometer. The constants used in this calculation were adjusted to correspond to the naturally occurring isotopic mixture.

PREVIOUS: June 1963 (1 atm) CURRENT: June 1963 (1 bar)

NITROGEN OXIDE, ION (NO^+) IDEAL GAS M_r = 30.00555

$S°(298.15\ K) = 198.219\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 983.995 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 990.185 \pm 0.8\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 2377.1\ cm^{-1}$ $\omega_e x_e = 16.35\ cm^{-1}$ $\sigma = 1$
$B_e = 2.002\ cm^{-1}$ $\alpha_e = 0.0202\ cm^{-1}$ $r_e = 1.0619\ Å$

Enthalpy of Formation

Watanabe (1) and Walker and Weissler (2) have measured the ionization potential of NO(g) by photoionization, yielding IP = 9.25±0.02 and 9.20±0.03 eV, respectively. Hagstrum (3), reported IP = 9.4±0.2 eV by electron impact. Huber (4) determined spectroscopically the ionization potential for NO(g), IP = 9.267±0.005 eV (213.72±0.1 kcal mol^{-1}). The last value has been selected, and yields the enthalpy of formation of $NO^+(g)$, $\Delta_f H°(NO^+, g, 0\ K)$ = 235.18 kcal mol^{-1}, using $\Delta_f H°(NO, g, 0\ K)$ = 21.46±0.04 kcal mol^{-1}.

Heat Capacity and Entropy

The selected molecular constants were obtained from the ultraviolet spectra by Miescher (5).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by Hilsenrath and Messina (6), who have used slightly different molecular constants.

756.8(1)
1665.5(1)

Ground State Quantum Weight: 2 $\sigma = 2$
Point Group: C_{2v}
Bond Distance: N-O = 1.197 Å
Bond Angle: O-N-O = 134° 15'
Product of the Moments of Inertia: $I_A I_B I_C = 1.54229 \times 10^{-116}\ g^3\ cm^6$

Enthalpy of Formation

The equilibrium constants for NO(g) + 1/2 O_2 + NO_2(g) of Bodenstein and Lindner (1), as given by Giauque and Kemp (2) were subjected to 2nd and 3rd law analysis. 3rd law analysis gave $\Delta_f H°(298.15\ K) = -13.67$ kcal mol^{-1} and 2nd law $\Delta_f H°(298.15\ K) = -13.52 \pm 0.01$ kcal mol^{-1}. The 3rd law value had a very slight trend with temperature which was consistent with an entropy error of 0.25 cal $K^{-1}\ mol^{-1}$, the 2nd law entropy was also consistent with an entropy error of 0.25 cal $K^{-1}\ mol^{-1}$. However the functions for all three gases are well established to about 0.03 cal $K^{-1}\ mol^{-1}$ or better and so this must be interpreted as due to errors in the data. On this basis the 3rd law value was chosen and combined with JANAF auxiliary data to give $\Delta_f H°(298.15\ K) = 7.91 \pm 0.2$ kcal mol^{-1}, where the uncertainty includes that due to the possible error in the equilibrium constants.

Heat Capacity and Entropy

Bird et al. have given a complete review of the microwave spectrum of NO_2. They also give a corrected infra-red vibrational assignment, adopted here, which is in excellent agreement with calculations from the microwave data. They report $I_A = 0.34981 \times 10^{-39}$, g cm^2 and $I_B = 6.45446 \times 10^{-39}$ g cm^2 and $I_C = 6.81994 \times 10^{-39}$ g cm^2. The bond length and angle were chosen to give the best fit of the moments of inertia.

Enthalpy of Formation

The recent literature concerning the electron affinity of $NO_2(g)$ is summarized in the following table.

Source	Technique	electron affinity $NO_2(g)$, eV
(1)	magnetron technique, direct electron-capture process	3.99 ± 0.16
(2)	endothermic charge transfer reaction	>2.04, >3.063
(3)	endothermic charge transfer reaction	2.30 ± 0.15
(4)	photodetachment of e^- from NO_2^- in argon matrix	<3.9
(5)	reaction of NO_2^- with HCl and HBr in flowing after glow system	<2.6
(6)	correlation between heats of hydration and heterolytic bond dissociation energies	2.5
(7)	charge transfer reactions, flowing after glow system	2.38 ± 0.06

The early literature on the electron affinity of $NO_2(g)$ is best summarized and referenced by Berkowitz et al. (2), Ferguson, et al. (5) and Dunkin, et al. (7). Much of these early data are not only widely scattered but also conflicting.

The value chosen for the electron affinity of $NO_2(g)$ is 2.38 ± 0.06 eV, based on the work of Dunkin et al. (7). This leads to $\Delta_f H°(NO_2^-, g, 298.15\ K) = -48.45 \pm 1.38\ kcal\ mol^{-1}$, using JANAF auxiliary data.

Heat Capacity and Entropy

The infrared spectrum of the NO_2^- ion isolated in an argon matrix was studied by Milligan et al. (4) and Milligan and Jacox (8). They reported that the antisymmetric stretching fundamental was $\nu_3 = 1244\ cm^{-1}$.

Hochstrasser and Marchetti (9), in combination with data from Sidman (10), reported $\nu_1 = 1325\ cm^{-1}$, $\nu_2 = 831\ cm^{-1}$, and $\nu_3 = 1243\ cm^{-1}$ as the vibrational frequencies of the nitrite ion in solution. These frequencies are also very similar to the values reported for $NO_2(g)$ by Herzberg (12). The ν_1 and ν_2 vibrational frequencies of $NO_2^-(g)$ were assumed to be the same as those for nitrite ion in solution (11). The value adopted for ν_3 was that of Milligan, et al. (4, 8).

Milligan, et al (4, 8), via studies of the infrared spectrum of NO_2^- ion isolated in an argon matrix, concluded that the isotopic data were consistent with a O-N-O angle of 115°. Hochstrasser and Marchetti (9), relying on crystallographic data for $NaNO_2(cr)$ collected by other investigators, reported the N-O bond distance as 1.23 ± 0.04 Å and the O-N-O bond angle as 115° ± 3°. The N-O bond distance in $NO_2^-(g)$ is assumed to be the same as that reported for $NaNO_2(cr)$.

The electronic states are estimated by analogy with the electronic levels of the isoelectronic molecule SO_2 (12).

Ground State Quantum Weight: 2 σ = [6]
Point Group: [D_{3h}]
Bond Distance: O-N = [1.2] Å
Bond Angle: O-N-O = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [5.311350 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation is based on equilibrium constants for the reaction $N_2O_5(g) \rightarrow NO_2(g) + NO_3(g)$ obtained from shock wave studies by Schott and Davidson (1). These equilibria give a 2nd law value of $\Delta_r H°(495\ K) = 21.5 \pm 1.4$ kcal mol^{-1}, corresponding to $\Delta_r H°(298.15\ K) = 22.2$ kcal mol^{-1}, and a 3rd law value of $\Delta_r H°(298.15\ K) = 22.2$ kcal mol^{-1}. The resulting enthalpy of formation is 17.0 kcal mol^{-1}.

Guillory and Johnston (2) report an equilibrium constant based on estimated Beer's law constants for NO_3 and attributed to the reaction $O_2 + NO \rightarrow NO_3$. This gives a 3rd law heat of formation of 12 ± 2 kcal mol^{-1} which was not considered. A tentative value of 23 kcal mol^{-1} (or greater) may be derived from the D° given by Ramsay (3).

Heat Capacity and Entropy

The structure and frequencies are those estimated by Hisatsune (4). A symmetry of D_{3h} was chosen on the basis of Walsh's (5) correlation, and the bond distance was taken as 2% longer than in the nitrate ion. The planar mode frequencies were calculated from estimated Urey-Bradley force constants, while the out-of-plane wagging frequency (765 cm^{-1}) was assumed the same as in $HNO_3(g)$.

There are several conflicting bits of information concerning NO_3 radicals. Chantry et al. (6) studied the electron resonance and optical absorption spectra of what appears to be NO_3 radicals trapped in crystals of urea nitrate. The authors suggest a planar structure without a threefold axis (thus C_s or C_{2v} symmetry), at least for the trapped radicals. Guillory and Johnston (2) report for gaseous NO_3 radicals an *infrared frequency at 1840 cm^{-1} which they assign as the N-O stretch.* The similarity of this frequency to those in N-O and X-N-O molecules led the authors to suggest an OONO structure (thus C_s symmetry) rather than the nitrate structure. The remaining frequences for such a structure may be crudely estimated by analogy with those measured for $(NO)_2$ by Smith et al. (7). Based on such frequencies and reasonable bond distances, *the room temperature entropy for the OONO* structure would be 68-72 cal K^{-1} mol^{-1}. Such an entropy is quite inconsistent with the 2nd law $\Delta_r S°(495\ K) = 33.2 \pm 3$ cal K^{-1} mol^{-1} for $N_2O_5(g) \rightarrow NO_2(g) + NO_3(g)$ obtained from the shock wave studies of Schott and Davidson. The Hisatsune functions based on the nitrate structure were selected because they are consistent with the experimental entropy. The principal moments of *inertia* for this structure are $I_A = I_B = 6.4277 \times 10^{-39}$ and $I_C = 12.8555 \times 10^{-39}$ g cm^2. A structure of C_{2v} symmetry would result if the nitrate structure were distorted to give one non-equivalent oxygen. Ramsay (3) suggests that such distortion can only be small, based on the high dispersion optical spectra of the gas phase.

PHOSPHORUS NITRIDE (PN) IDEAL GAS M_r = 44.98046

$S°(298.15\ K) = 211.137\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 105.77 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 104.78 \pm 5.0\ kJ\ mol^{-1}$

Electronic Level and Multiplicity

State	ε_i, cm^{-1}	g_i
$^1\Sigma^+$	0	1

$\omega_e = 1337.24\ cm^{-1}$ $\omega_e x_e = 6.983\ cm^{-1}$ $\sigma = 1$
$B_e = 0.7862\ cm^{-1}$ $\alpha_e = 0.00557\ cm^{-1}$ $r_e = 1.4910$ Å

Enthalpy of Formation

The selected $\Delta_f H°(298.15\ K)$ was calculated from the $D_0^0 = 165.8 \pm 1.2$ kcal mol^{-1} reported by Potter and DiStefano (1). $D_0^0 = 163.7 \pm 1.2$ kcal mol^{-1} was experimentally determined by Huffman et al. (2). The D_0^0 reported by Huffman et al. (2) was derived using a pressure-composition method, i.e., measurement of equilibrium vapor pressure, at 1173 K for the reaction [PN(g) + P_2(g) + N_2(g)]. Potter and DiStefano (1) recalculated Huffman's results to obtain their D_0^0 value. Gaydon (3) lists a $D_0^0 = 138.4 \pm 19$ kcal mol^{-1}. The corresponding enthalpy of formation are:

Source	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
Potter and DiStefano (1)	25.0 ± 1.2
Huffman et al. (2)	27.1 ± 1.2
Gaydon (3)	53 ± 19

Heat Capacity and Entropy

The molecular constants are taken from Herzburg (4).

Enthalpy of Formation

A linear Birge-Sponer extrapolation of the ground state gives a dissociation energy of 142.9 kcal mol^{-1}. The ground state can correlate with normal atoms $Si(^3P) + N(^4S)$ or with $Si(^3P) + N(^2D)$; in this latter case D_0^0 would be 88 kcal mol^{-1}. The uncertainty in the extrapolation is quite large, ±30 kcal mol^{-1}, since only 6 levels, of the estimated total of 87 levels, are observed.

A dissociation energy can also be calculated from the $B^2\Sigma^+$ state by a much shorter extrapolation. This extrapolation is done graphically since some curvature is evident in the first six levels. A value of $D_0^0(B^2\Sigma)$ = 50.4 kcal mol^{-1} is obtained. This corresponds to $D_0^0(X^2\Sigma)$ = 119.9 kcal mol^{-1} for normal products or $D_0^0(X^2\Sigma)$ = 65 kcal mol^{-1} for excited nitrogen as a product. The uncertainty in this extrapolation is less than the ground state and is probably ±20 kcal mol^{-1}.

An estimate of $D_0^0(SiN)$ may be obtained by equating $D_0^0(SiN)/D_0^0(SiO) = D_0^0(CN)/D_0^0(CO)$; this yields $D_0^0(SiN)$ = 135 kcal mol^{-1}.

A comparison of the isoelectronic molecules CP, BS and BeCl and the related molecules CN, BO, BeF indicates $D_0^0(SiN) > 115$ kcal mol^{-1}.

A value of $D_0^0(SiN)$ = 130 ± 15 kcal mol^{-1} is in agreement within the uncertainties of both ground state and B state extrapolations assuming normal atoms as products, and is in agreement with the other estimates. This value is adopted and yields $\Delta_f H°(SiN, g, 298.15\ K)$ = 89 kcal mol^{-1}.

Heat Capacity and Entropy

The B-X transition has been reported by Jenkins and de Laszlo (1). The rotational and vibrational constants are derived from their work and adjusted to normal isotopic abundance. The $A^2\Pi$-$C^2\Pi$ transition has been observed by Shetlar (2). The height of the A state is estimated by correlation with CP(g). The level of the B state is taken from Herzberg (3).

Enthalpy of Formation

Zmbov and Margrave (1) have identified $Si_2N(g)$ in a mass spectrometer. They also determined partial pressures of $Si_2N(g)$ in equilibrium with Si(g) and $N_2(g)$. From four of these measurements, in the temperature range 1742 - 1846 K, we obtain a 2nd law $\Delta_r H°(298.15\ K)$ = 99.6±6 kcal mol^{-1} for the reaction $Si_2N(g) = 2\ Si(g) + 0.5\ N_2(g)$; and a 3rd law $\Delta_r H°(298.15\ K)$ = 120.2 kcal mol^{-1} with a drift of -11.4±3.4 cal K^{-1} mol^{-1}. Considering the small temperature range and the uncertainties in the free energy functions, the data appear consistent. We adopt the 3rd law enthalpy of reaction which yields $\Delta_f H°(Si_2N, g, 298.15\ K)$ = 95 kcal mol^{-1}.

Heat Capacity and Entropy

$Si_2N(g)$ is considered to be closely related to $C_2N(g)$, and its structure and electronic configuration are adopted by analogy to this species. The bond length was obtained by adding the difference between the bond distances of SiN(g) and CN(g) to the bond length in CNC(g). The vibrational frequencies were estimated by comparison with several molecules, CNC(g); $^1\pi$ state of $C_3(g)$; NCN(g); and $Si_2C(g)$. It should be noted that there is a wide variation in observed frequencies for these molecules and ν_1 and ν_3 may be significantly different from the chosen values.

The electronic ground state is considered to be $^2\pi g$ with excited states of $^2\Delta_u$ and $^2\Sigma_u^-$ as in the case of CNC(g). The levels are obtained from those in CNC(g) by use of the shift between $C_3(g)$ and SiCSi(g).

PREVIOUS: March 1967 (1 atm) CURRENT: March 1967 (1 bar)

TITANIUM NITRIDE (TiN) CRYSTAL M_r = 61.8867

$S°(298.15\ K) = 30.235 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3220 \pm 50\ K$

$\Delta_f H°(0\ K) = -333.971 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -337.649 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [66.944]\ kJ\ mol^{-1}$

Enthalpy of Formation

Humphrey (1) and Neumann et al. (2) determined the enthalpy of combustion of titanium nitride by burning the material in an oxygen bomb calorimeter. For reaction (a) Humphrey obtained $\Delta_r H°(298.15\ K) = -145.05 \pm 0.14\ kcal\ mol^{-1}$ and Neumann et al., $\Delta_r H°(298.15\ K) = -145.0\ kcal\ mol^{-1}$. From an examination of the combustion products Humphrey reported that the TiO_2 was >95 percent rutile and <5 percent anatase, but made no correction for the anatase. The adopted $\Delta_f H°(298.15\ K) = -80.7\ kcal\ mol^{-1}$ is the average of three values, two from Humphrey (-80.75, -80.61) one as reported and one corrected for anatase and one from Neumann et al. (-80.8). The uncertainty in the adopted enthalpy is due mainly to the uncertainty in the enthalpy of formation of rutile. Hoch et al. (3) determined the vapor pressure of reaction (b), in the temperature range 1987-2241 K, using a Knudsen effusion method. 3rd law analysis of the data yields $\Delta_f H°(298.15\ K) = -79.5\ kcal\ mol^{-1}$. Linevsky (4) obtained the titanium partial pressures of reaction (C) at fixed nitrogen pressures using atomic absorption spectroscopy. 3rd law analysis of the data gives a $\Delta_f H°(298.15\ K) = -81 \pm 18\ kcal\ mol^{-1}$. These equilibrium measurements were not considered in deriving the heat of formation due to their large uncertainties in comparison to the calorimetric data.

Source	Method	Reaction	T/K	$\Delta_r H°(298.15\ K)$ kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	Calorimeter	(a) $TiN(cr) + O_2(g) \rightarrow TiO_2(rutile) + 1/2\ N_2(g)$	298	-145.05±.14			-80.75
(1)	Calorimeter	(a) $TiN(cr) + O_2(g) \rightarrow TiO_2(rutile) + 1/2\ N_2(g)$	298	-145.05±.14			-80.61*
(2)	Calorimeter	(a) $TiN(cr) + O_2(g) \rightarrow TiO_2(rutile) + 1/2\ N_2(g)$	298	-145.0			-80.80
(3)	Equilibrium	(b) $TiN(cr) \rightarrow Ti(g) + 1/2\ N_2(g)$	1987-2241	212±9	192.5	-9.3±4.3	-79.5
(4)	Equilibrium	(c) $TiN(cr) \rightarrow Ti(g) + 1/2\ N_2(g)$	2088-2141	230±17	194.2	-17±8	-81.2

*Assumes that the product TiO_2 is 95 percent rutile and 5 percent antase.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52-296 K) of Shomate (5). Naylor (6) measured high temperature heat contents (388-1738 K). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 1738 K the heat capacity is graphically extrapolated. The entropy is based on $S°(50;0) = 0.138\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

See the liquid table for details.

TITANIUM NITRIDE (TiN) LIQUID M_r = 61.8867

$S°(298.15\ K) = [52.733]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3220 \pm 50\ K$

$\Delta_f H°(298.15\ K) = [-265.813]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [66.944]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(TiN, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(TiN, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(3220\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200 K. Below 2200 K the heat capacity is obtained from the heat capacity of the crystal. Above 2200 K it is assumed constant and estimated as 15 cal K^{-1} mol^{-1} or 7.5 cal K^{-1} g-atom. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} is taken from Agte and Moers (1). $\Delta_{fus} H°$ is derived from an estimated $\Delta_m S°$ = 2.5 cal K^{-1} g-atom as suggested by Kubaschewski et al. (2).

VANADIUM NITRIDE (VN) CRYSTAL M_r = 64.9482

$S°(298.15\ K) = 37.264 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -214.403 \pm 5.0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -217.150 \pm 5.0\ kJ\ mol^{-1}$

Enthalpy of Formation

Mah (1) measured the enthalpy of combustion of vanadium mononitride at 303.15 K. The composition of the sample was $VN_{1.00}$ which corresponds to the nitrogen-rich boundary of the mononitride phase (see Phase Data section). Chemical analysis also showed that the sample contained 0.07 weight percent of unreacted vanadium. The composition of the combustion products ranged from $VO_{2.231}$ to $VO_{2.296}$. X-ray diffraction patterns showed the solid combustion products to be a mixture of V_2O_4 and V_2O_5. JANAF enthalpy of formation data (2) for these two oxides are used to correct Mah's combustion values to correspond to the formation of the pentoxide as the final state. Our values for this correction agree with those of Mah (1) to within 0.1 cal K^{-1} mol^{-1} mononitride. For the process $VN(cr) + 1.25\ O_2(g) = 0.5\ V_2O_5(cr) + 0.5\ N_2(g)$, we obtain $\Delta_c H° = -133.41 \pm 0.43$ kcal mol^{-1} at unit fugacities of oxygen and nitrogen. When this value is combined with the enthalpy of formation of V_2O_5 (2), that for vanadium mononitride is $\Delta_f H°(VN, cr, 298.15\ K) = -51.9 \pm 1.2$ kcal mol^{-1}. We adopt this value and include in the overall uncertainty (±1.2 kcal mol^{-1}) the error associated with correcting the combustion values for the $V_2O_4(cr)$ formed to $V_2O_5(cr)$ as the final state.

Other values for $\Delta_f H°$ can be derived from the results of dissociation pressure measurements (3), emf data (4), and equilibrium data (5) obtained by an effusion-mass spectrometric technique. Analyses of these data are summarized below.

Source	Method	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$-\Delta_f H°(298.15\ K)$ kcal mol^{-1}
Slade and Higson (3)	Static	A	2	1476-1544	-68.8	-41.1±1.8	-18.3	41.1
Voleinik and Shabdenov (4)	emf	A	Equation	363-403	-54.4	-55.5±0.1	-2.7	55.5±0.1
Farber and Srivastava (5)	Mass Spec.	B	13	1900-2412	173.5	181.7±1.6	3.8±0.8	58.5±3.6

Reactions: A) $V(cr) + 0.5\ N_2(g) = VN(cr)$ B) $VN(cr) = V(g) + 0.5\ N_2(g)$

Results obtained from the dissociation pressures of Slade and Higson (3) are obviously not reliable. Two other more extensive sets of dissociation pressure data (6, 7) have been reported for the mononitride phase. Brauer and Schnell (6) measured the nitrogen dissociation pressures for $VN_{0.72}$ between 1573 and 1873 K, while Kozheurov et al. (7) determined equilibrium pressures for VN_x (x = 0.55-0.9) at temperatures in the range 1573-1923 K. Unfortunately, these compositions are significantly different from $VN_{1.00}$, and thus the data are probably of no use in defining the enthalpy of formation of the mononitride at its nitrogen-rich phase boundary. The 3rd law values of $\Delta_f H°$ obtained from the emf (4) and mass spectral (5) data are 3.6 and 6.6 kcal mol^{-1}, respectively, more negative than our adopted value. However, since the thermal functions used in the analysis of the mass spectral data (5) are based on extrapolated data, the 2nd law value, $\Delta_f H°(298.15\ K) = -50.3$ kcal mol^{-1}, is probably more reliable. This value is in much better agreement with that obtained by combustion calorimetry.

Heat Capacity and Entropy

Shomate and Kelley (8, 52.6-296.3 K) measured the low temperature heat capacities for VN. The purity of the mononitride sample based on an analysis for vanadium by permanganate titration was found to be 99.76 weight percent. Their $C_p°$ data corrected to 1969 Atomic Weight Scale are adopted. S°(298.15 K) is obtained from the adopted $C_p°$ data and is based on S°(52 K) = 0.47 cal K^{-1} mol^{-1}. This latter value is calculated from the Debye function D(351/T) which was suggested by Shomate and Kelley (8).

High temperature enthalpies for VN have been reported by King (9) for the temperature range 408-1611 K. The sample was identical to that employed by Shomate and Kelley (8) and was contained in platinum-rhodium alloy capsules for the "drop" experiments. His experimental enthalpies are corrected to refer to the 1969 Atomic Weight Scale. Also, his reported temperatures are corrected to the IPTS-68 scale. A technique based on orthogonal polynomials is used to fit the corrected enthalpies by computer. The curve is constrained to join smoothly with the low temperature $C_p°$ data (8) near 298 K. Our smoothed enthalpies show an average deviation of ±0.4% from the experimental values (9). The maximum deviation is +2.1% at 408 K. No anomalies are observed in either the low temperature $C_p°$ data (8) or the high temperature enthalpies (9). $C_p°$ data above 1613 K are obtained by graphical extrapolation. Satoh (10) has measured the mean specific heats of VN over three temperature intervals by means of an ice calorimeter. However, the sample used in his study was impure (97.93% VN), and we believe the results are probably not reliable. They do show considerable scatter from our adopted results; deviations are in the range of ±1-5%.

Phase Data

The mononitride phase has been prepared by several workers (1, 5-8, and 11-13) at temperatures as high as 1600 K. X-ray data (6, 11) and dissociation pressure measurements (7) have shown that the phase has an extensive homogeneity range. Although Kozeurov et al. (7) were unable to obtain $VN_{1.00}$ at 1273 K, Brauer and Schnell (6) and Hahn (11) reported that the composition of the mononitride phase extends from $VN_{0.72}$ to $VN_{1.00}$ (42 to 50 atomic percent nitrogen) at 1273-1873 K. The dissociation pressure data of Kozheurov et al. (7) indicate that the vanadium-rich phase boundary decreases from $VN_{0.7}$ at 1573 K to $VN_{0.56}$ at 1923 K. The structure of the mononitride is face-centered cubic (6, 11). Further information on the vanadium-vanadium nitride system has been reviewed by Storms (14).

Decomposition Data

The melting point of VN has been reported to be approximately 2323 K by Rostoker and Yamamoto (15). However, Farber and Srivastava (5) in their mass spectrometric studies observed solid nitride at temperatures as high as 2412 K. Liquid vanadium metal, presumably formed from decomposition of the nitride, was deposited in the sample. We assume that VN decomposes to its elements prior to melting. T_{dcm} = 2619 K is the temperature at which the fugacity is 1 atm for the decomposition reaction VN(cr) + V(ℓ) + 0.5 N_2(g) approaches zero. $\Delta_{dcm}H°$ is the negative of the heat of formation of VN(cr) at T_{dcm}.

Enthalpy of Formation

Dissociation energies for the diatomic group III-VI transition-metal nitrides have been estimated by Gingerich (1) and provide support for the existence of these gaseous molecules. Very recently, mass-spectrometric evidence (2) has been presented which verifies the existence of VN(g). Using an effusion-mass spectrometric technique, Farber and Srivastava (2) observed the VN^+ ion as one of the vapor species in equilibrium with solid VN in the temperature range 1900-2412 K. The molecular precursor of this ion is assumed to be VN(g). Results of effusion weight loss and mass spectrometric experiments (2) were combined to yield partial pressures for the species involved in the following two reactions: (A) VN(cr) = VN(g) and (B) VN(g) = V(g) + 0.5 N_2(g). During the course of these experiments, the ion intensities for each species did not show any variation with time. This implies that the mononitride phase remained at near unit activity during their measurements.

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(2)	A	1900-2412	13	174.3	185.4±2.4	5.2±1.4	133.5±3.6
(2)	B	1900-2412	12*	-1.9	-3.6±1.6	-0.8±1.4	126.8±3.6

*One point rejected due to failure of a statistical test.

The 3rd law value of 126.8±3.6 kcal mol^{-1} for $\Delta_f H°$ is considered to be more reliable than that (133.5 kcal mol^{-1}) derived from the sublimation data, since the results for the gas phase reaction (B) show the least drift. Also, Farber and Srivastava (2) reported a 2nd law value determined from ion intensity plots of $\Delta_r H° = 3 \pm 5$ kcal mol^{-1} for reaction (B) at 2162 K. Using auxiliary data (3), this value leads to $\Delta_f H°(VN, g, 298.15\ K) = 122.0 \pm 7.0$ kcal mol^{-1}. We adopt $\Delta_f H°(VN, g, 298.15\ K) = 125.0 \pm 5.0$ kcal mol^{-1} which is a weighted average of the 3rd law value derived from reaction (B) and the 2nd law value based on ion intensity plots. The adopted $\Delta_f H°$ value corresponds to a bond dissociation energy, D°(298.5 K), of 111.2 kcal mol^{-1}. This compares favorably with the value (116 kcal mol^{-1}) estimated by Gingerich (1).

Heat Capacity and Entropy

The value of r_e(VN) is obtained from the expression $r_e(MO)-r_e(MN) = -0.023$ A with $r_e(VO) = 1.589$ A (3). Differences in the bond lengths (4) for the oxides and nitrides of As, B, P, Si, and Ti are used to establish the value -0.023. B_e is calculated from the estimated value for r_e. The value of α_e is obtained from the other constants assuming a Morse potential function. The values of ω_e and $\omega_e x_e$ are assumed to lie between those for TiO(g) and AsN(g) (4). VN is isoelectronic with TiO. Farber and Srivastava (2) have estimated a somewhat higher value (1065 cm^{-1}) for ω_e. However, their estimate is based partially on estimated JANAF data (3) for ZrN(g).

The ground state electronic configuration ($^3\Delta$), upper electronic levels and quantum weights are estimated by analogy with those for TiO (3, 5). It is possible, however, that the ground state for VN is $^1\Delta$. VN is also isoelectronic with ScF and ZrO which both have singlet ground states (5). If the adopted ground state and first excited state are interchanged, then the value of S°(298.15 K) is reduced by 1.94 cal K^{-1} mol^{-1}. Our adopted upper levels and quantum weights contribute 0.61 and 1.11 cal k^{-1} mol^{-1} to the entropy of VN(g) at 2000 and 4000 K, respectively.

PREVIOUS: December 1973 (1 atm) CURRENT: December 1973 (1 bar)

ZIRCONIUM NITRIDE (ZrN) CRYSTAL M_r = 105.2267

$S°(298.15\ K) = 38.861 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [3225\ K]$

$\Delta_f H°(0\ K) = -362.020 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -365.263 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [67.362]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of reaction I, -174.25 ± 0.30 kcal mol^{-1}, was measured by Mah and Gelbert (7). The $\Delta_f H°(298.15\ K)$ of ZrN was obtained using -261.5 ± 0.2 kcal mol^{-1} for $\Delta_f H°(298.15\ K)$ of ZrO_2. For the same reaction, Neumann et al. (1) obtain -176.0 kcal mol^{-1} on a sample of unspecified purity. Vapor pressure measurements of Hoch et al. (2) lead to -81 kcal mol^{-1} for the $\Delta_f H°(298.15\ K)$ of ZrN. However, this value is uncertain by 10% as evidenced by the work on ZrO_2 by Chupka et al. (3).

$$\text{(I)}\quad ZrN(cr) + O_2(g) = ZrO_2(cr) + 1/2\ N_2(g)$$

Heat Capacity and Entropy

Low temperature measurements, 53-297 K, of Todd (4) were smoothly joined to those of Coughlin and King (5), 298-1073 K.

Fusion Data

Estimated by Henderson and Scheffee (6).

ZIRCONIUM NITRIDE (ZrN) LIQUID M_r = 105.2267

$S°(298.15\ K) = [62.342]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = [3225]\ K$

$\Delta_f H°(298.15\ K) = [-290.749]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [67.362]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(ZrN, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, H°(3225 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Calculated from the solid. The heat capacity function of the solid was assumed to approximate those of the liquid up to the estimated glass point of 2150 K. Above the glass point the heat capacity was estimated.

$S°(ZrN, \ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Zirconium Nitride (ZrN) $N_1Zr_1(l)$

ZIRCONIUM NITRIDE (ZrN) IDEAL GAS M_r = 105.2267

$S°(298.15\ K) = [233.487]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [714.342]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [713.372]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^2\Sigma]$	0	[2]

$\omega_e = [840]\ cm^{-1}$ $\omega_e x_e = [5]\ cm^{-1}$ $\sigma = 1$
$B_e = [0.4146]\ cm^{-1}$ $\alpha_e = [0.0025]\ cm^{-1}$ $r_e = [1.83]$ Å

Enthalpy of Formation

$\Delta_f H°(0\ K)$ was estimated as 170.7 kcal mol^{-1} by Gordon (1). $\Delta_f H°(298.15\ K)$ was then calculated.

Heat Capacity and Entropy

Molecular constants were estimated by Gordon (1). r_e was calculated from the relationship $r_e = (16.858778/\mu B_e)^{1/2}$ Å.

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

These are calculated by combining direct summation of vibrational-rotational energy levels of the electronic ground state with an approximate correction for the contribution of three excited states. All spectroscopic constants are from Lofthus and Krupenie (1) except the vibrational polynomial G used in direct summation of the ground state. We revise the G equation (1) so that is converges near $D_0^o = 78715\ cm^{-1}$ (2, 1). Experimental data are limited to $v \leq 27$ and there is uncertainty in the extrapolation to high v values. Methods proposed by Khachkuruzov (3) are used to approximate the infinite-series (F) equation for rotational levels and the limiting values (J_{max}) of rotational quantum number. Values in the J_{max} equation are estimated by comparison with Khachkuruzov (3) and Gurvich et al. (4).

Contributions of excited states begin to appear in Cp° at ~4800 K. We obtain these contributions using the difference between approximate calculations for four states (X, A, B, and W) and one state (ground state). These approximate calculations used first-order corrections for anharmonicity and vibrational-rotational interaction. The excited state contribution to Cp° is 0.019 $cal^{-1}\ K^{-1}\ mol^{-1}$ at 5000 K.

Values and uncertainties at 298.15 K are the same as those selected by CODATA (2). Uncertainties at 6000 K are considerably larger due to uncertainity in the extrapolation of G and F. Comparing our approximate calculation (a) with our adopted values (b) and those (c) of Gurvich et al. (4), we have S°(600 K) = 69.981, 69.999 and 70.005 $cal^{-1}\ mol^{-1}$ and H(T) - H(0 K) = 51.196, 51.271, and 51.289 J $K\ mol^{-1}$.

Enthalpy of Formation

The adopted value for the enthalpy of formation of N_2^+(g), $\Delta_f H°(0\ K) = 359.298 \pm 0.01\ kcal\ mol^{-1}$ is recommended in a critical review on the energetics of gaseous ions by Rosenstock et al. (1). This value is derived from ionization potentials determined in the spectroscopic studies of Worley (2) and Ogawa and Tanaka (3); the IP values are 125665.8 and 125666.8 cm^{-1} respectively.

$\Delta_f H°(N_2^+, 298.15\ K)$ is obtained from $\Delta_f H°(N_2, g, 0\ K)$ by using IP (N_2, g, 0 K) with JANAF (7) enthalpies H°(0 K) - H°(298.15) for N_2(g), N_2(g), and e^-(g). $\Delta_r H°(298.15)$ for the reaction $N_2(g) = N_2^+(g) + e^-(g)$ differs from a room temperature threshold energy due to the inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (1). $\Delta_f H°(298.15)$ should be changed by -6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

The thermal functions are calculated using the program of McBride and Gordon (4). The contributions of vibrational anharmonicity and rotation-vibration interaction are calculated via the procedures given by Pennington and Kobe (5). In this procedure the energy levels are calculated as follows: $\varepsilon_1 = T_o + G(v) - G(o) + B_v J(J+1) - D_e J^2(J+1)^2$ where $G(v) = \omega_e(v + 1/2) - \omega_e x_e(v + 1/2)^2 + \omega_e y_e(v + 1/2)^3$ and $B_v = B_e - \alpha_e(v + 1/2)$. When a value of D_e is not available, it is calculated to be $D_e = 4B_e^3/\omega_e^2$. Molecular constant data in the table are from the critical review of Lofthus and Krupenie (6). Electronic levels above 5000 cm^{-1} given by Lofthus and Krupenie are not included since they make negligible contributions to the thermodynamic properties at 6000 K.

$S°(298.15\ K) = 204.54 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 155 \pm 96\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [148.615]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^2\Pi g$	0	4

$\omega_e = [1900]\ cm^{-1}$ $\omega_e x_e = [12.0]\ cm^{-1}$ $\sigma = 2$

$B_e = [1.691]\ cm^{-1}$ $\alpha_e = [0.015]\ cm^{-1}$ $r_e = [1.193 \pm 0.003]$ Å

Enthalpy of Formation

The enthalpy of formation at 0 K for $N_2^-(g)$ is based on the electron affinity value derived from the Rydberg-Klein-type calculations of Gilmore (1). Use of this adopted value, $EA(N_2) = -1.6 \pm 1.0$ eV and auxiliary data (2) leads to $\Delta_f H° = 37 \pm 23$ kJ mol^{-1} and $D_0^0(N_2^-) = 190 \pm 30$ kJ mol^{-1}. *Additional discussion on $N_2^-(g)$ may be found in the reviews by Lofthus and Krupenie (3) and Massey (4).*

The adopted EA is the only tabulated value for the ground state given in a recent compilation by Rosenstock et al. (5). This compilation contains results through the end of 1973. In support of the adopted value there are two additional studies to consider. First, Massey (4) discusses qualitatively the electronic and molecular structure as follows. The ground state of N_2 has a closed shell configuration. The corresponding configuration for N_2^- is obtained by adding an additional electron in an antibonding Πg 2p orbital. According to Mulliken's rule this reduces the binding energy by about 1.25 eV (~29 kJ mol^{-1}). In contrast to $O_2^-(g)$, in the separated atom limit the ion N_2^- is not stable so that we expect the lowest level of N_2^- will be at least 1.25 eV above that for N_2 as well as occurring at a larger nuclear separation. Second, Birtwistle and Herzenberg (6) developed a theory of vibrational excitation through an intermediate state which predicts that the lowest energies of N_2^- and N_2 are separated by 1.925 eV (~44 kJ mol^{-1}). Comparable results were obtained by Krauss and Mies (7) using a variational method.

$\Delta_f H°(0\ K)$ is converted to $\Delta_f H°(298.15\ 0\ K)$ by use of JANAF (2) enthalpies $H°(0\ K) - H°(298.15\ K)$ for $N_2(g)$, $N_2^-(g)$, and $e^-(g)$. $\Delta_f H°(298.15\ K)$ should be changed by +1.481 kJ mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

The vibrational constants are estimated based on trends implied in isoelectronic sequences involving (N_2^-, NO, and O_2^+) and (N_2 and NO^+). The value adopted for ω_e is ~35 cm^{-1} and ~65 cm^{-1} lower than those calculated by Krauss and Mies (7) and Birtwistle and Herzenberg (6), respectively.

We adopt the $r_e = 1.193 \pm 0.003$ Å value calculated by Birtwistle and Herzenberg (6) as it agrees with the value suggested from the above isoelectronic series. The calculations of Krauss and Mies (7) suggest $r_e = 1.22$ Å which, in our estimation, is too high. B_e is calculated from r_e while α_e is estimated from the aforementioned isoelectronic series. This α_e value is the same as one would calculate assuming a Morse potential for the electronic ground state.

No low lying excited states are assumed to exist (3, 4).

Enthalpy of Formation

An analysis of the enthalpy of reaction data is summarized below. Carlton-Sutton et al. (1) studied the direct decomposition at pressures of 40 to 50 atmospheres and made P-V-T measurements in order to reduce the data. They obtained a similar but less certain enthalpy of formation by combustion of N_2O in CO. Flame calorimetric measurements of the combustion by Awberry and Griffiths (2) are in good agreement, but the bomb calorimetry of Fenning and Cotton (3) gives a enthalpy of formation about 0.2 kcal mol^{-1} larger. The selected enthalpy of formation is a weighted average of these values.

Source	Method	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
(1)	Bomb calorimetry	$N_2O(g) + N_2(g) + 0.5\ O_2(g)$	-19.52 ± 0.10	19.52
(1)	Bomb calorimetry	$N_2O(g) + CO(g) + CO_2(g) + N_2(g)$	-87.10 ± 0.30	19.46*
(2)	Flame calorimetry	$N_2O(g) + CO(g) + CO_2(g) + N_2(g)$	-87.09 ± 0.22	19.45*
(3)	Bomb calorimetry	$N_2O(g) + CO(g) + CO_2(g) + N_2(g)$	-87.37 ± 0.12	19.73*
(3)	Bomb calorimetry	$N_2O(g) + H_2(g) + H_2O(\ell) + N_2(g)$	-88.03 ± 0.12	19.71*

*Based on $\Delta_f H°(298.15\ K) = -68.32\ (H_2O,\ \ell)$, $-94.054\ (CO_2,\ g)$, $-26.417\ (CO,\ g)$

Heat Capacity and Entropy

The functions are based on the rotational constants of Pliva (4) and the frequencies determined by Tidwell et al. (5). The bond distances reported by Pliva were obtained from measurements of isotopic shifts in the infrared. They include higher-order corrections for vibration-rotation interaction and are in satisfactory agreement with the infrared and microwave studies of Douglas and Moller (6) and the electron diffraction data of Schomaker and Spurr (7).

Enthalpy of Formation

The ionization potential of 104000 cm^{-1} (297.35 kcal mol^{-1}) has been obtained by Tanaka et al. (1) from a Rydberg series terminating on $X^2\pi_{3/2}$. Other Rydberg series terminating on $X^2\pi_{1/2}$ and $A^2\Sigma^+$ were also obtained and confirm the adopted value. This value in conjunction with the enthalpy of formation of $N_2O(g)$ (2) was used to calculate the adopted enthalpy of formation.

Heat Capacity and Entropy

The electronic, vibrational and rotational constants are those reported by Herzberg (3) from the work of Callomon and Creutzberg (4).

Ground State Quantum Weight: 1 σ = 1

Point Group: C_s

Bond Distances: N-N = 2.08 Å N-O (nitroso) = 1.12 Å

N-O(nitro) = 1.18 Å

Bond Angles: O-N-N (nitroso) = 110° O-N-O = 134°

Product of Moments of Inertia: $I_A I_B I_C = 4.6201 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

Equilibria for the reaction $N_2O_3(g) \rightarrow NO(g) + NO_2(g)$ have been studied by Beattie and Bell (1), Verhoek and Daniels (2), and Abel and Proisl (3). The results of Beattie and Bell are the most extensive, but they depend on the early analysis of Giauque and Kemp (4) for the simultaneous equilbrium $N_2O_4(g) \rightarrow 2\ NO_2(g)$. The JANAF analysis of the tetroxide dissociation has been used to recalculate the data of Beattie and Bell. Non-ideality of N_2O_4 and NO_2 was allowed for by use of the equations of state of Giauque and Kemp, while non-ideality of NO and N_2O_3 was removed by extrapolation of the equilibrium constants to zero pressure in a manner similar to that of Beattie and Bell. The data of Verhoek and Daniels and of Abel and Proisl have not been recalculated. 2nd and 3rd law analyses of the results are summarized below. The enthalpy of formation was obtained from $\Delta_r H°(298.15\ K) = 9.70$ kcal mol^{-1}.

Source	Temp. Range	T/K	$\Delta_r S°$, cal K^{-1} mol^{-1} 2nd law	3rd law	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law

a) given by authors b) from author's K_p values c) from recalculated K_p values

Heat Capacity and Entropy

The functions are similar to those calculated by Hisatsune (5) based on the analysis of Devlin and Hisatsune (6) of the Raman and infrared spectra in terms of Urey - Bradley force constants. Devlin and Hisatsune used observed isotopic shifts in the spectra along with force constants transferred from nitrogen oxides and oxyhalides in order to select the N-N bond distance and the O-N-N bond angle.

The unobserved mode was assumed to be free internal rotation around the N-N bond, leading to $S°(298.15\ K) = 73.91$ cal K^{-1} mol^{-1} which is in good agreement with 74.13 ± 0.52 cal K^{-1} mol^{-1} obtained from the recalculated 2nd law of Beattie and Bell. The principal moments of inertia are $I_A = 22.694 \times 10^{-39}$, $I_B = 29.577 \times 10^{-39}$, and $I_C = 6.883 \times 10^{-39}$ g cm^2, while the reduced moment for internal rotation was calculated as $I_r = 0.990 \times 10^{-39}$ g cm^2.

NITROGEN OXIDE (N_2O_4) CRYSTAL M_r = 92.0110

$S°(298.15\ K) = 150.290\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 261.95 \pm 0.05\ K$

$\Delta_f H°(0\ K) = -30.399 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -35.046 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 14.652 \pm 0.013\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was calculated from that of the liquid using the measured enthalpy of melting and the enthalpy of the crystal and liquid.

Heat Capacity and Entropy

Giauque and Kemp (1) measured the low temperature heat capacity from 15-295 K. The entropy was obtained by integration of these data using $S°(15\ K) = 0.34\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

The temperature and enthalpy of fusion were also measured by Giauque and Kemp (1).

NITROGEN OXIDE (N_2O_4) LIQUID M_r = 92.0110

$S°(298.15\ K) = 209.198\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 261.95 \pm 0.05\ K$

$\Delta_f H°(298.15\ K) = -19.564 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 14.652 \pm 0.013\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation was calculated from that of the gas using the calorimetrically measured enthalpy of vaporization to the equilibrium mixture, in conjunction with the fraction of NO_2 dimerized $\alpha = 0.161$.

Heat Capacity and Entropy

Giauque and Kemp (1) measured the low temperature heat capacity from 15-295 K. Above 295 K the heat capacity was smoothly extrapolated. $S°(l, 298.15\ K)$ is calculated from $C_p°$.

Fusion and Vaporization Data

Giauque and Kemp (1) measured the temperature and enthalpy of fusion and also the boiling point and the calorimetric value of the enthalpy of vaporization to the equilibrium mixture. *The enthalpy of vaporization* (f = 1 atm) to a hypothetical pure N_2O_4 gas at 294.25 K was calculated to be 6.91 kcal mol^{-1}.

1373 (1)	1710(1)	1748(1)
823 (1)	480(1)	385(1)
260 (1)	430(1)	1261(1)
[50](1)	675(1)	750(1)

Ground State Quantum Weight: 1 $\sigma = 4$
Point Group: D_{2h}
Bond Distances: N-N = 1.750 Å N-O = 1.180 Å
Bond Angle: O-N-O = 133.7°
Product of the Moments of Inertia: $I_A I_B I_C = 9.935917 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

Giauque and Kemp (1) calculated idealized equilibrium constants for the reaction $N_2O_4(g) = 2\ NO_2(g)$ from the work of Bodenstein and Boes (2), Verhoek and Daniels (3) and Wourtzel (4). The 2nd and 3rd law analysis of these equilibrium constants has been repeated using more recent functions. The results are shown below.

Source	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law
(2)	13.634 ± 0.015*	13.644
(3)	14.429 ± 0.126	13.672
(4)	13.599 ± 0.019**	13.657

*Ten points rejected because of statistically significant scatter.
**One point rejected.

The 2nd law value of Verhoek and Daniels (3) was not considered significant due to the extremely small temperature range and the use of only three temperatures. The adopted value was 13.65 ± 0.03 kcal mol^{-1} which leads to 2.17 kcal mol^{-1} for the enthalpy of formation of $N_2O_4(g)$.

Heat Capacity and Entropy

The structural parameters were taken from the electron diffraction measurements of Smith and Hedberg (5). The vibrational frequencies are those chosen by Hitsatsune et al. (6). The torsional frequency of 50 cm^{-1} was estimated in order to bring the entropy of the gas into agreement with that determined by Giauque and Kemp (1) from low temperature heat capacities and heats of fusion and vaporization. The principal moments of inertia are: $I_A = 12.5103 \times 10^{-39}$, $I_B = 22.6126 \times 10^{-39}$ and $I_C = 35.1229 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

The enthalpy of formation was obtained by recalculation of the calorimetric data of Ray and Ogg for the reaction of $N_2O_5(g)$ with NO. The stoichiometry of the reaction products, originally based on the results for $N_2O_4 \rightarrow 2\ NO_2$ from Giauque and Kemp (1) was based on the JANAF analysis of this simultaneous equilibrium. A correction of 0.29 kcal mol^{-1} was made in the enthalpy of reaction because of the additional formation of N_2O_3 from NO and NO_2.

Confirmation of the enthalpy of formation was obtained by combination of the enthalpies of hydrolysis and sublimation of $N_2O_5(cr)$. The results are summarized below. 2nd law values are given for the enthalpies of sublimation, but 3rd law analyses suggest that the value from Russ and Pokorny (4) is more reliable. Most of the uncertainty in this path, however, arises from the enthalpy of hydrolysis.

Source	Method	Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(2)	Calorimetric	$N_2O_5(g) + NO(g) \rightarrow 0.724\ NO_2(g) + 1.138\ N_2O_4(g)$	-16.05 ± 0.20	2.67
(3)	Calorimetric	$N_2O_5(cr) + H_2O(\ell) \rightarrow 2\ HNO_3(aq)$	-20.2 ± 0.5	--
(4)	Vapor Pressure	$N_2O_5(cr) \rightarrow N_2O_5(g)$	13.37 ± 0.06	2.79*
(5)	Vapor Pressure	$N_2O_5(cr) \rightarrow N_2O_5(g)$	13.25 ± 0.12	2.67*

*Using reaction 2 and $\Delta_f H°(298.15\ K) = -68.32(H_2O, \ell), -49.55(HNO_3, aq)$.

Heat Capacity and Entropy

Ray and Ogg (6) reported $S°(298.15\ K) = 85 \pm 0.5$ cal $K^{-1}\ mol^{-1}$ from combination of kinetic and thermochemical values. This entropy was recalculated as follows. The rate data of Ray and Ogg (6) and of Daniels and Johnston (7) give for the reaction $N_2O_5(g) + NO(g) \rightarrow NO_2(g) + O_2(g)$ at 25°C the equilibrium constant $K = 5.15 \times 10^{-7}$ $moles^2\ liter^{-2} = 3.08 \times 10^{-4}\ atm^2$. The resulting value of $\Delta_r H°(298.15\ K) = 4.79$ kcal mol^{-1} leads to $S°(298.15\ K) = 82.8$ cal $K^{-1}\ mol^{-1}$ for $N_2O_5(g)$ when combined with the JANAF entropies and heats of formation of the components of the reaction.

The molecular structure is the nonplanar configuration from the electron diffraction study of Akishin et al. (8). A planar model (also point group C_{2v}) was assumed by Hisatsune et al. (9) in their approximate normal coordinate analysis of the infrared and Raman spectra. The frequency assignments of these authors are listed above in the order for the planar model, although the vibrations for the nonplanar form will separate differently into the species $5A_1$, $3A_2$, $3B_1$ and $4B_2$. Hisatsune et al. (9) estimated the N-O'-N deformation frequency (8 cm^{-1}) from combination bands in the solid and gas phase spectra. The JANAF thermodynamic functions were obtained using these frequencies and assuming the two NO_2 groups to be hindered internal rotators. Barriers to internal rotation of 4.4 kcal mol^{-1} (corresponding to torsional vibratons of about 55 cm^{-1}) were selected in order to give the observed entropy at room temperature. The principal moments of inertia for the nonplanar model were taken as $I_A = 30.60 \times 10^{-39}$, $I_B = 40.15 \times 10^{-39}$ and $I_C = 16.82 \times 10^{-39}$ g cm^2, while $I_r = 4.693 \times 10^{-39}$ g cm^2 was used for the reduced moment of inertia of the O_2 tops.

Bond Angle: N-N-N = 180°
Rotational Constant: $B_0 = 0.431085\ cm^{-1}$

Enthalpy of Formation

Okabe and Mele (1) have measured the photodissociation onset of the process

$CN{\cdot}N_3(g) \rightarrow CN(g) + N_3(g)$ $\Delta H°(0\ K) = 96 \pm 2.5\ kcal\ mol^{-1}$

Using a value of $\Delta_f H°(CN{\cdot}N_3, g, 298.15\ K) = 107 \pm 3\ kcal\ mol^{-1}$ and $\Delta_f H°(CN, g, 298.15\ K) = 104 \pm 2.5\ kcal\ mol^{-1}$ (2), we derive $\Delta_f H°(N_3, g, 298.15\ K) = 99 \pm 5\ kcal\ mol^{-1}$. The enthalpy of formation of $CN{\cdot}N_3$ is obtained from $\Delta_f H°(CN{\cdot}N_3, cr, 298.15\ K) = 92.6 \pm 3\ kcal\ mol^{-1}$ (3) and an estimated $\Delta_{sub}H°(298.15\ K) = 14.4 \pm 3\ kcal\ mol^{-1}$. The enthalpy of sublimation is similar to that for ICN(cr) (2). A rough confirmation of $\Delta_{sub}H°$ can be made by assuming a boiling point of 227°C (500 K), from the facts that $CN{\cdot}N_3$ sublimes in vacuo at 40°C and can be heated as a liquid to 170°C. Thus, using the Trouton rule, $\Delta_{vap}H° = 11\ kcal\ mol^{-1}$, in addition the enthalpy of melting would be expected to be about 3.6 kcal mol^{-1} for this 5 atom molecule, thus $\Delta_{sub}H° = 14.6\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The electronic levels and rotational constants have been reported by Douglas and Jones (4) and Thrush (5). The vibrational frequencies were estimated from the isoelectronic species NCO, NNO^+, and the related molecules NCN and NNO (2).

$S°(298.15\ K) = [112.967 \pm 16.7]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -744.752 \pm 29.3\ kJ\ mol^{-1}$

Enthalpy of Formation

The equilibria (A) $Si_3N_4(cr) = 3\ Si(\ell) + 2\ N_2(g)$ and (B) $Si_3N_4(cr) = 3\ Si(cr) + 2\ N_2(g)$ have been investigated by three groups. Pehlke and Elliott (1) made four series of measurements which mainly concerned reaction (A). Hincke and Brantley (2) made a single series of measurements which covered reactions (A) and (B). Matignon (3) also gave a single equilibrium point for reaction (C) $3\ SiO_2(cr) + 6\ C + 2\ N_2 = Si_3N_4(cr) + 6\ CO(g)$. Below are shown 2nd and 3rd law analyses of the data. It should be noted that these analyses are based on the estimated enthalpy capacities above 900 K and on an estimated entropy. The uncertainty due to these estimates is estimated as $\pm$ 7 kcal mol^{-1} in $\Delta_f H°(298.15\ K)$.

**Four points rejected due to failure of a statistical test; this set is a combination of the first four sets.

The adopted $\Delta_f H°(\alpha\text{-}Si_3N_4,\ 298.15\ K) = -178 \pm 7$ kcal mol^{-1}.

McClaine and Coppel (4) have investigated the decomposition reaction (B). The conclude that at 1618 K the equilibrium pressure is roughly 0.15 mm. This corresponds to $\Delta_f H°(298.15\ K) = 182.3$ kcal mol^{-1}, and was not given any weight in the adopted value.

Heat Capacity and Entropy

The enthalpy of α-Si_3N_4 has been measured at three temperatures, in the range 373 - 858 K, by Sato (5). The heat capacity is Calculated from the data assuming that a limit of 45 cal K^{-1} mol^{-1} is attained by 3000 K. The entropy is obtained from the equilibrium data of Pehlke and Elliott (1).

Decomposition Data

The temperature of decomposition, T_{dcm} = 2151 K, is calculated as the point at which the decomposition pressure of nitrogen reaches a fugacity of 1 atm.

PHOSPHORUS NITRIDE (P_3N_5) CRYSTAL M_r = 162.95478

$S°(298.15\ K) = [184.096 \pm 25.1]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -320.155 \pm 20.9\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is based on the work of Stock and Wrede (1) who burned P_3N_5 in oxygen. They report a $\Delta_r H°(298.15\ K) = -949.4\ kcal\ mol^{-1}$ for the reaction $2\ P_3N_5(cr) + 7.5\ O_2(g) = 1.5\ P_4O_{10}(amorph) + 5\ N_2(g)$. In (2) a value of $-947.7\ kcal\ mol^{-1}$ is used for the above reaction and we adopt this value. Using the JANAF value of $P_4O_{10}(cr)$ and correcting this to $P_4O_{10}(amorph)$ by adding $-13.8\ kcal\ mol^{-1}$, from (2) we obtain $\Delta_f H°(298.15\ K)\ P_4O_{10}(amorph) = -716.5\ kcal\ mol^{-1}$. Thus, we derive $\Delta_f H°(P_3N_5, cr, 298.15\ K) = -63.525\ kcal\ mol^{-1}$; however, because of the uncertainties in the enthalpy of reaction and correction for amorphous P_4O_{10}, we round the value to $-64 \pm 5\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

Sato (3) gave an equation for the heat capacity in the range 273 - 578 K. Judging from his results for $Be_3N_2(cr)$ in the same paper, we believe his values will be slightly high at the upper end of the range. Thus, taking 8.2 cal K^{-1} g-atom as the limiting value, a curve was drawn through Sato's values at the low end and approaching the limit asympototically. The entropy was estimated from that of $Si_3N_4(cr)$ by assuming that the ratio $C_p°(298.15\ K)/S°(298.15\ K)$ on a gram atom basis would be the same for $P_3N_5(cr)$.

Decomposition Data

T_{dcm} = 730 K is calculated as the point at which the total pressure reaches a fugacity of 1 atm. This corresponds to $\log K_p° = -0.76$ for the reaction $P_3N_5(cr) = 0.75\ P_4(g) + 2.5\ N_2(g)$. The temperature of decomposition has been reported by Postnikov and Kuzmin (4) as 1073 K. This has been confirmed by Moreau and Rocquet (5) and Huffman et al. (6). However, it was also noted that $P_3N_5(cr)$ is not reformed on cooling the decomposition products; thus the decomposition is non-equilibrium. It is known that the decomposition of AlN, BN and Be_3N_2 is kinetically limited and the equilibrium pressure is not attained until the average energy is greater than the activation energy. It appears that this is also the case for P_3N_5 and a high activation energy is expected.

Sodium (Na) $Na_1(ref)$

$S°(298.15\ K) = 51.455\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 370.98 \pm 0.02\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 2.602\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Martin (1) reports that the low temperature heat capacity of sodium depends on the thermal history of the sample and ascribes this to a martensitic transformation. The effect is most pronounced in the range 40-80 K, where the graph of C_p against T increases continuously for some samples and rises to a peak at 55 K for others. Martin (1) lists heat capacities obtained in several runs on "high purity" sodium at 21 to 300 K and the higher values, those defining the peak at 55 K, have been selected here. The heat capacities reported by Dauphinee et al. (2), have not been used, since one of the authors in a later publication, Martin (1) questions the accuracy of the measurements above 100 K, and at lower temperatures there is no rise to a peak at 55 K. In the range 1.5 to 20 K, Roberts (3) and Parkinson and Quarrington (4) have measured the heat capacity of very high purity sodium. The values of Parkinson and Quarrington (4) are somewhat higher than those of Roberts (3) and have been given greater weight, since they show better continuity with Martin's (1) results. The results of Pickard and Simon (5) have been rejected below 10 K, since they show a peak between 5 and 8 K, a feature not verified by other workers; between 10 and 25 K they agree exactly with the results of Parkinson and Quarrington (4). Rayne (6) states that the graph of C_p against T has a small peak at about 0.9 K. This peak has not been observed in the work of Lien and Phillips (7) from 0.15 to 1 K; Gaumer and Heer from 0.4 to 2 K and Martin (9) from 0.4 to 1.5 K.

Douglas et al. (10) report heat capacities in the range 273 to 1173 K on a sample of not less than 99.9% purity. These values agree to within 1% with those of Martin (1) in the range 273 to 300 K, and the two sets of dates have been smoothly joined.

Fusion Data

Douglas et al. (10) have determined the triple point to be 97.82 ± 0.02°C, from which the melting point is calculated to be 97.83 ± 0.02°C, and have measured the enthalpy of fusion.

Sublimation Data

At the boiling point and higher temperatures sodium vapor contains an appreciable proportion of diatomic moleculses. Thompson and Garelis (11) have made a careful analysis of the available vapor pressure data. Their results are consistent with the Gibbs energy functions calculated in the present work and have been adopted.

PREVIOUS: CURRENT: June 1962

$S°(298.15\ K) = [57.862]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 370.98 \pm 0.02\ K$

$\Delta_f H°(298.15\ K) = [2.406]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 2.602\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Na, \ell, 298.15\ K)$ is calculated from that of the crystal by adding the enthalpy of fusion and the difference in enthalpy, $H°(370.98\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The liquid heat capacity values are derived from the enthalpy measurements of Douglas et al. (1). The heat capacity curve was extrapolated to 298.15 K and 2000 K in a reasonable manner.

The entropy is calculated in a manner anologous to that used for the enthalpy of formation.

Fusion Data

The enthalpy of fusion and the melting point were measured by Douglas et al. (1).

Vaporization Data

Sodium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm at 1156 K. The vapor pressure of the monatomic gas reaches 1 atm at 1176.9 K and the enthalpy of vaporization to monatomic gas is 23.285 kcal mol^{-1}.

Enthalpy of Formation

The enthalpy of formation of sodium gas, $\Delta_f H°(298.15\ K)$ = 107.5 ± 0.7 kJ mol^{-1}, is chosen to be the value recommended by CODATA (1). This value was obtained from 2nd and 3rd law treatment of vapor pressure data. The reported vapor pressures were corrected for the effects of $Na_2(g)$, using D_0^0 = 70.63 kJ mol^{-1}. At higher pressures, an alternate virial treatment was employed.

As stated by CODATA (1), the selected value is the weighted average of the 3rd law values of $\Delta_{sub}H°(298.15\ K)$ calculated from the following:

Source	$\Delta_{sub}H°(298.15\ K)$, kJ mol^{-1}
Haycock and Lamplough (2)	107.52 ± 0.68
Rodebush and Devries (3)	107.37 ± 0.60
Thiele (4)	107.99 ± 0.60
Kis Tiakowsky (5)	107.38 ± 0.70
Makansi et al. (6)	107.18 ± 0.95
Shpil'rain and Belova (7)	107.26 ± 0.78
Sowa (8)	107.60 ± 1.35
Stone et al. (9)	107.68 ± 1.33
Achener and Jouthas (10)	107.85 ± 0.80
Vinogradov and Volyak (11)	107.44 ± 0.60
Bohdansky and Schins (12)	107.47 ± 1.00
Schins et al. (13)	107.36 ± 1.22

The 2nd law calculations from the above sources led to somewhat more positive values(1).

Heat Capacity and Entropy

The thermal functions for the five alkali metal monatomic gases are calculated by the same procedure. Oberved and estimated atomic energy levels are included in the partition function calculation, using an ionization potential lowering (IP-kT) technique as the cutoff procedure in the energy level summation (15).

The lowest lying levels for these metals [14904 cm^{-1} (Li), 16956 cm^{-1} (Na), 12985 cm^{-1} (K), 12578 cm^{-1} (Cs)] do not contribute to the thermal functions below ~1000 K; there is only a translational contribution below this temperature. Above this approximate temperature, the thermal functions become increasingly sensitive to the partition function cutoff procedure used, due to the combined effect of the observation of atomic energy levels of high principal quantum number and a low ionization potential. Energy levels have been observed up to n = 42 (Li), 59(Na), 79(K), 77(Rb), and 73(Cs). However, not all predicted levels have been observed for each of these principal quantum numbers. The ionization potentials vary from 43487.29 cm^{-1} for Li to 31406.1 cm^{-1} for Cs. In calculating the thermal functions with the inclusion of missing levels up to the high principal quantum numbers just mentioned, the Gibbs energy functions show significant differences (depending on the cutoff procedure) above 3000 K (15).

The atomic energy levels have been taken from the compilation of Martin and Zalubas (14). Our calculated values for the thermal functions are similar to those recommended by CODATA (1). They do differ for two reasons, however. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, the entropies at 298.15 K for all alkali metal gases differs by ~0.004 J K^{-1} mol^{-1}, presumably due to the use of slightly different values for auxiliary data.

Enthalpy of Formation

$\Delta_f H°(Na^+, g, 0\ K)$ is calculated from $\Delta_f H°(Na, g, 0\ K)$ (1) using the spectroscopic value of IP(Na) = 41449.44 ± 0.03 cm^{-1} (495.846 ± 0.000 kJ mol^{-1}) from Martin and Zolubas (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Na^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Na, g, 0\ K)$ by using IP(Na) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Na(g), $Na^+(g)$, and $e^-(g)$. $\Delta_r H°(Na \rightarrow Na^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Martin and Zolubas (2), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (6) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state; the first excited state is approximately 264924 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (6).

Enthalpy of Formation

The enthalpy of formation, at 0 K, for $Na^-(g)$ is calculated from the adopted electron affinity, EA(Na, g) = 0.547930 ± 0.000025 eV (52.867 ± 0.002 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (6), was measured by a tunable laser detachment threshold technique (2). Additional discussion on $Na^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (1, 6), Rosenstock et al. (3), and Massey (4).

$\Delta_f H°(Na^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Na, g, 0\ K)$ by using EA(Na, g) with JANAF (5) enthalpies, $H°(0\ K)-H°(298.15\ K)$, for $Na^-(g)$, Na(g), and $e^-(g)$. $\Delta_r H°(Na^- + Na + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Na^-(g)$ is given by Hotop and Lineberger (1, 6) and Rosenstock et al. (3). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

Enthalpy of Formation

Bawn and Evans (1) studied the reaction rate of sodium vapor with nitrous oxide, nitrogen peroxide, nitromethane, ethyl nitrate and amyl nitrite, using the diffusion flame method. On the evidence of reaction rate measurements they estimated the value, $\Delta_r H°(298.15\ K) < 0$, for the reaction $Na(g) + NO_2(g) = NaO(g) + NO(g)$. Based on this result, we calculate $\Delta_f H°(NaO, g, 298.15\ K) > 12\ kcal\ mol^{-1}$, using $\Delta_f H°(298.15\ K) = 25.8$, 7.9 and 21.6 kcal mol^{-1} for Na(g), NO_2(g) and NO(g), respectively.

Assuming that $D_0^0(NaO) = 1/2\ [D_0^0(Na_2) + D_0^0(O_2)]$, or $\Delta_r H°(0\ K) = 68.1\ kcal\ mol^{-1}$ for the reaction NaO(g) = Na(g) + O(g), we derive $\Delta_f H° = 16.7$ and $\Delta_f H°(298.15\ K) = 16.4\ kcal\ mol^{-1}$, using $\Delta_r H°(0\ K) = 25.8$ and 59.0 kcal mol^{-1} for Na(g) and O(g), respectively.

Somayajulu (2) found that in a sequence of similar diatomic molecules the force constant (k_e), dissociation energy (D_0^0) and equilibrium bond distance (r_e) are related by the expression $k_e r_e (D_0^0)$ = constant. Using $r_e = 1.62$ Å, $D_0^0 = 77.9\ kcal\ mol^{-1}$ for LiO(g), $r_e = 2.0$ Å for NaO(g) and $k_e(NaO)/k_e(LiO) = 0.4827$, we evaluate $D_0^0 = 65.4\ kcal\ mol^{-1}$ for NaO(g), yielding $\Delta_f H°(NaO, g, 298.15\ K) = 19.4\ kcal\ mol^{-1}$. The value k_e is calculated from the relation $k_e = 4\pi^2\nu^2\mu$ where τ is the vibrational frequency of the diatomic molecule and μ is the reduced mass.

The value of $\Delta_f H°(NaO, g, 298.15\ K)$ is tentatively adopted as 20 ± 10 kcal mol^{-1}. The corresponding $D_0^0(NaO)$ is 65 ± 10 kcal mol^{-1}.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for OH(g) which has the same number of valence electrons as NaO(g). The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for LiO(g), LiF(g) and NaF(g). The value of r_e is estimated from those for OH(g), HF(g) and NaF(g). B_e and α_e are derived from r_e, ω_e and $\omega_e x_e$ by the method suggested by Herzberg (3).

$S°(298.15\ K) = [217.49 \pm 2.1]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = [-113.76 \pm 83.7]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [-121.34 \pm 83.7]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$[^1\Sigma]$	0	[1]

$\omega_e = [450]\ cm^{-1}$ $\omega_e x_e = [3.2]\ cm^{-1}$ $\sigma = 1$
$B_e = [0.4467]\ cm^{-1}$ $\alpha_e = [0.00495]\ cm^{-1}$ $r_e = [2.0]$ Å

Enthalpy of Formation

The electron affinity of $NaO^-(g)$ is unavailable, therefore the value of $\Delta_f H°(NaO^-, g, 298.15\ K)$ is estimated. We first assume that the enthalpy change $\Delta_r H°(0\ K)$ of the reaction (1) $NaO^-(g) = Na(g) + O^-(g)$ is close to the average of the $\Delta_r H°(0\ K)$ values for the reactions (2) $NaO(g) = Na(g) + O(g)$ and (3) $NaF(g) = Na(g) + F(g)$. The atom F(g) is isoelectronic with $O^-(g)$. In other words, the $\Delta_r H°(0\ K)$ for reaction (1) is approximately 1/2 (64.8 + 113.9) = 89.3 kcal mol^{-1}. Then we compare the $\Delta_r H°(0\ K)$ values for the reactions (4) $HO(g) = H(g) + O(g)$, (5) $HO^-(g) = H(g) + O^-(g)$, and (6) $HF(g) = H(g) + F(g)$, and find that $\Delta_r H°(0\ K)$ *for reaction (5) is experimentally determined as 109.7 kcal mol*$^{-1}$ *which is about 8 kcal mol*$^{-1}$ *more negative than the average of* $\Delta_r H°(0\ K)$ values for reactions (4) and (6). Based on this fact we estimate $\Delta_r H°(0\ K) = 80$ kcal mol^{-1} for reaction (1), yielding $\Delta_f H°(NaO^-, g, 298.15\ K) = -29$ kcal mol^{-1} which is tenatively adopted. The uncertainty of this value may be ±20 kcal mol^{-1}. Based on this $\Delta_f H°(298.15\ K)$ value we calculate E. A. = 2.1 ± 0.9 eV for NaO(g). The corresponding value for HO(g) is 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of NaF(g) which is isoelectronic with $NaO^-(g)$. The values of ω_e, $\omega_e x_e$ and r_e are estimated by comparison with the observed data for NaF(g). The values of B_e and α_e are calculated from r_e, ω_e and $\omega_e x_e$ using the method recommended by Herzberg (1).

PREVIOUS: December 1967 (1 atm) CURRENT: December 1967 (1 bar)

$S°(298.15\ K) = 115.90 \pm 1.3\ J\ K^{-1}\ mol^{-1}$
$T_{trs1} = 196.5\ K$
$T_{trs2} = 223.3\ K$
$T_{fus} = 825 \pm 10\ K$

$\Delta_f H°(0\ K) = -263.88 \pm 2.9\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -260.66\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = 1464.400\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = 1548.080\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ was obtained from (1). Giles and Margrave (2) measured the enthalpy of decomposition of NaO_2(cr) in H_2O, yielding $\Delta_f H°(298.15\ K) = -62.1 \pm 0.7\ kcal\ mol^{-1}$. From the original experimental data by de Forcrand (3), the value of $\Delta_f H°(298.15\ K)$ was recalculated to be $-65.0\ kcal\ mol^{-1}$ by Gilles and Margrave (2).

Heat Capacity and Entropy

The low temperature heat capacities, 52.13 ~ 296.46 K, were measured by Todd (4). The heat capacities above 298.15 K were estimated by comparison with those for Na_2O(cr). S°(298.15 K) was given by Todd (4) using $S°(51\ K) = 2.23\ cal\ K^{-1}\ mol^{-1}$ (extrap.).

Transition Data

T_{trs1}, T_{trs2}, $\Delta_{trs1} H°$ and $\Delta_{trs2} H°$ were calculated from the data reported by Todd (4).

Fusion Data

The melting temperature was obtained from Margrave (5).

Enthalpy of Formation

Using the adopted value of the dissociation energy for $Na_2(g)$, D_0^0 = 71.113 kJ mol^{-1} (2), and the recommended $\Delta_f H°(Na, g, 0\ K)$ = 107.32 kJ mol^{-1} from NBS (7), we calculate $\Delta_f H°(Na_2, g, 0\ K)$ = 143.51 kJ mol^{-1}. Since this value is only 1.05 kJ mol^{-1} smaller than the NBS recommended value of 144.56 kJ mol^{-1} (7) we adopt the NBS result. Correcting this value to 298.15 K using the current value of $H°(298.15\ K)-H°(0\ K)$ = 10403.27 J K^{-1} mol^{-1} for Na_2 and the NBS value of $H°(298.15\ K)-H°(0\ K)$ for Na(cr) (1) we obtain $\Delta_f H°(Na_2, g, 298.15\ K)$ = 142.05 kJ mol^{-1}.

Heat Capacity and Entropy

The heat capacity and entropy were calculated using a direct summation technique similar to the $Li_2(g)$ calculation (see $Li_2(g)$ table) using data recommended by Stwalley (1, 2) for the ground state. Reliable spectroscopic data for the lower lying excited states of Na_2 is sparse. Only the $^1\Sigma_u^+$ state at T_e = 14680.6 cm^{-1} has been experimentally characterized with any degree of confidence (3, 6). Theoretical calculations by Konowalow, Rosenkrantz and Olson (4) show that the relative ordering of states is equivalent to that of $Li_2(g)$ (see $Li_2(g)$ table). Since the excited state contribution to all thermodynamic functions (except for the heat capacity) for $Li_2(g)$ was small (~0.2% at 6000 K) we decided to treat the excited states for $Na_2(g)$ in an approximate way as follows. First, the $^3\Sigma_u^+$ state was neglected entirely due to the extremely shallow potential well (The $^3\Sigma_u^+$ state of $Li_2(g)$ contributes insignificantly to the thermodynamic functions.) Second, the $^3\Pi_u$, $^1\Sigma_u^+$, and $^3\Sigma_g^+$ states were combined as a single $^1\Sigma_u^+$ state using the spectroscopic constants of Kamimsky (5) and an artifical degeneracy of 10 (6 for the $^3\Pi_u$, 1 for the $^1\Sigma_u^+$, and 3 for the $^3\Sigma_g^+$ state). This procedure certainly overestimates the $^3\Sigma_g^+$ contribution (which lies above the $^1\Sigma_u^+$ state by ca. 3300 cm^{-1}) but at the same time underestimates the $^3\Pi_u$ contribution (which lies below the $^1\Sigma_u^+$ state by ca 1100 cm^{-1}) (4). In any case the contribution to the Gibbs energy function is very small (< 0.01 J K^{-1} mol^{-1}) at temperatures below 2500 K and only contributes ca. 3 J mol^{-1} K^{-1} at 6000 K. Note also that the Dunham coefficients for the ground state are reported to higher order in (6) than used in the calculation. The neglect of these higher order terms results in uncertainties similar to the $Li_2(g)$ calculation (the Gibbs energy function at 6000 K is probably only 0.3 J K^{-1} mol^{-1} smaller than the truncated rovib expression method). The rotational levels of the ground state were weighted in accordance with the nuclear spin of 3/2 (even J weight = 0.625, odd J weight = 0.375). The adopted value of $S°(298.15\ K)$ is only 0.1 J K^{-1} mol^{-1} lower than that adopted by NBS (7).

$S°(298.15\ K) = 75.042\ J\ K^{-1}\ mol^{-1}$
$T_{trs}(\gamma \rightarrow \beta) = 1023.2\ K$
$T_{trs}(\beta \rightarrow \alpha) = 1243.2\ K$
$T_{fus} = 1405.2\ K$

$\Delta_f H°(0\ K) = -413.15 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -417.98 \pm 4.2\ kJ\ mol^{-1}$
$\Delta_{trs}H°(\gamma \rightarrow \beta) = 1.757\ kJ\ mol^{-1}$
$\Delta_{trs}H°(\beta \rightarrow \alpha) = 11.924\ kJ\ mol^{-1}$
$\Delta_{fus}H° = 47.698\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy change of the reaction $Na_2O(cr) + H_2O(\ell) = 2\ NaOH(aq)$ has been determined by Matsui (1, 2), Roth (3, 4) and Rengade (5). Based on their reported $\Delta_r H°$ values, the corresponding $\Delta_f H°(298.15\ K)$ for $Na_2O(cr)$ are calculated, using $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.315\ kcal\ mol^{-1}$ obtained from (6) and $\Delta_f H°(NaOH, nH_2O, 298.15\ K)$ derived from JANAF $\Delta_f H°(NaOH, cr, 298.15\ K)$ and $\Delta_{sln}H°$ and $\Delta_{dil}H°$ reported by Parker (7). The sample employed by Matsui was prepared by the method of Rengade (9) and contains $Na_2O(cr)$ and Na(cr) as impurities. The sample used by Roth also contains 3.96% (by weight) $Na_2O_2(cr)$. Corrections in the reported results for such impurities have been made by the authors. However, in order to obtain better results, more measurements using purer samples are necessary. The enthalpy change of the reaciton $2\ Na(cr) + H_2O(\ell) = Na_2O(cr) + H_2(g)$ was calculated by Rengade (5) from his measurements (5) incorporating with $\Delta_r H° = -85.2\ kcal\ mol^{-1}$ for the reaction $2\ Na(cr) + 2\ H_2O(\ell) = 2\ NaOH(aq) + H_2(g)$ determined by Joannis (10). The value $\Delta_f H°(298.15\ K) = -94.9\ kcal\ mol^{-1}$ is derived from the data of Forcrand (8) using $\Delta_f H°(Na_2O_2, cr, 298.15\ K) = -122.66\ kcal\ mol^{-1}$. The results are presented in the table below.

Brewer (13) determined the equilibrium constants, 918-1467 K, for the vaporization of $Na_2O(cr)$, using an effusion method. The Na_2O vapor consists predominately of Na(g) and $O_2(g)$ molecules with any oxide molecules being not important. The Na/O ratio was not measured and assumed to be 2/1 in all calculations on Na_2O. Based on the reported data, we derive the equilibrium constants for the reaction $Na_2O(cr) = 2\ Na(g) + 1/2\ O_2(g)$ and evaluate the 3rd law $\Delta_r H°(298.15\ K)$ as $117.1 \pm 10\ kcal\ mol^{-1}$. From this $\Delta_r H°(298.15\ K)$ value, we obtain $\Delta_f H°(Na_2O, cr, 298.15\ K) = -65.6 \pm 10\ kcal\ mol^{-1}$, employing $\Delta_f H°(298.15\ K)$ for Na(g). The value $-65.6\ kcal\ mol^{-1}$ is not consistent with the other values described above. This may be caused by an invalid assumption used in the calculation.

The enthalpy of formation at 298.15 K for $Na_2O(cr)$ is tentatively selected as $-99.90 \pm 1.0\ kcal\ mol^{-1}$.

Source	Reaction	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	$Na_2O(cr) + H_2O(\ell) = 2\ NaOH(7890\ H_2O)$	-56.61 ± 0.16	-100.08
(2)	$Na_2O(cr) + H_2O(\ell) = 2\ NaOH(4600\ H_2O)$	-56.70 ± 0.07	-99.89
(3)	$Na_2O(cr) + H_2O(\ell) = 2\ NaOH(825\ H_2O)$	-56.03 ± 0.13	-100.55
(4)	$Na_2O(cr) + H_2O(\ell) = 2\ NaOH(825\ H_2O)$	-55.98 ± 0.13	-100.60
(5)	$Na_2O(cr) + H_2O(\ell) = 2\ NaOH(aq)$	-56.50	-100.09
	$2\ Na(cr) + H_2O(\ell) = Na_2O(cr) + H_2(g)$	-28.70	-97.02
(8)	$Na_2O(cr) + 1/2\ O_2(g) = Na_2O_2(cr)$	-27.76	-94.90

Heat Capacity and Entropy

The low temperature heat capacities, 15-380 K, were obtained from Furukawa (11). We make the corrections in the reported $C_p°$ values for impurity $Na_2CO_3(cr)$ 2.33% (by weight), analyzed by Grimley (12). The effect on heat capacity due to the presence of Na_2O_2(0.91%) impurity is insignificant. Using the smoothed low temperature $C_p°$ data, the S°(298.15 K) is calculated, based on $S°(15\ K) = 0.0122\ cal\ K^{-1}\ mol^{-1}$.

Grimley (12) measured the high temperature enthalpies, 380.1-1174.6 K, with a copper block drop-type calorimeter. The enthalpies for the γ phase, 380.1-980.4 K, are joined smoothly with the low temperature data and extrapolated to 1023.2 K (the γ → β transition temperature). The enthalpies above 1023.2 K are obtained by extrapolation. The enthalpies measured at 1078.3 and 1174.6 K by Grimley are unreasonably large, and are not adopted.

Transition Data

The transition temperature and heats of transition were determined calorimetrically by Bouaziz (14) who used a very pure sample. The adopted $\Delta_{trs}H° = 0.42$ and 2.85 $kcal\ mol^{-1}$, are averages of the derived values, 0.36 - 0.48 and 2.7 - 3.0 $kcal\ mol^{-1}$, respectively.

Fusion Data

T_{fus} and $\Delta_{fus}H°$ were obtained from Bouaziz (14). The adopted $\Delta_{fus}H°$ is an average of the reported 10.8-12.0 $kcal\ mol^{-1}$. T_{fus} has been reported as 1193 and 1190 ± 10 K by Bunzel (15) and Brewer (13), respectively, which are not adopted.

SODIUM OXIDE (Na_2O) LIQUID M_r = 61.97894

$S°(298.15\ K) = [91.607]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1405.2\ K$

$\Delta_f H°(298.15\ K) = [-372.843]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 47.698\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Na_2O, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Na_2O, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1405.2\ K) - H°(298.15\ K)$, between $Na_2O(cr)$ and $Na_2O(\ell)$.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $Na_2SiO_3(\ell)$ and $SiO_2(\ell)$. $S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Decomposition Data

$T_{dcm} = 2223\ K$ is the temperature at which the fugacity of oxygen is one atmosphere for the decomposition reaction $Na_2O(\ell) = 2\ Na(g) + 1/2\ O_2(g)$.

Sodium Oxide (Na_2O) Na_2O_1(cr,l)

$S°(298.15\ K) = 94.80 \pm 1.3\ J\ K^{-1}\ mol^{-1}$
$T_{trs} \approx 785 \pm 1\ K$
$T_{fus} \approx 948\ K$

$\Delta_f H°(0\ K) = -507.34 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -513.21 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 5.732\ kJ\ mol^{-1}$
$\Delta_{fus} H°$ = Unknown

Enthalpy of Formation

The enthalpy change of the reaction $Na_2O_2(cr) + H_2O(\ell) = 2\ NaOH(aq, 1200\ H_2O) + 1/2\ O_2(g)$ was measured at 18.5°C by Roth (1). He employed a sample with composition 96.81% Na_2O_2 and 3.4% Na_2O by weight. Using $\Delta_{sln}H°(Na_2O_2, cr) = -56.02\ kcal\ mol^{-1}$, Roth derived the value $\Delta_{sln}H°(Na_2O_2, cr) = -34.85\ kcal\ mol^{-1}$. This value was later corrected to be -35.75 kcal mol^{-1} (2). From these data we calculate the enthalpy of formation (298.15 K) of $Na_2O_2(cr)$ as -121.0 kcal mol^{-1}. Forcrand obtained $\Delta_{sln}H° = -36.65$ kcal mol^{-1} for the same reaction, quoted by Roth (1), yielding $\Delta_f H°(Na_2O_2, cr, 298.15\ K) = -120.0\ kcal\ mol^{-1}$. The auxiliary data $\Delta_f H°(H_2O, \ell, 298.15\ K) = -68.315\ kcal\ mol^{-1}$ is taken from (3); and $\Delta_f H°(NaOH{\cdot}aq, 1200\ H_2O, 298.15\ K) = -112.458\ kcal\ mol^{-1}$ is derived based on $\Delta_f H°(NaOH, cr, 298.15\ K) = -101.90\ kcal\ mol^{-1}$ from JANAF Table and $\Delta_{sol}H°(aq, \infty) = -10.637\ kcal\ mol^{-1}$ and $\Delta_{dil}H°(aq, 1200\ H_2O \rightarrow aq, \infty) = -0.079\ kcal\ mol^{-1}$ from Parker (4).

Gilles (5) determined the enthalpy change of the reaction $Na_2O_2(cr) + H_2O(\ell) = 2\ NaOH(aq, 3800\ H_2O) + 1/2\ O_2(g)$, using a purer sample ($Na_2O_2$, 99.2%; Na_2O, 0.8%). Based on the reported value $\Delta_r H°(298.15\ K) = -34.0 \pm 0.3\ kcal\ mol^{-1}$ and derived $\Delta_f H°(NaOH{\cdot}aq, 3800\ H_2O, 298.15\ K) = -112.487\ kcal\ mol^{-1}$, we calculate $\Delta_f H°(298.15\ K) = -122.66 \pm 1.2\ kcal\ mol^{-1}$ for $Na_2O_2(cr)$.

Leffler (6) studied the oxygen pressure-melt composition for the liquid sodium-oxygen system between 780 and 980°C. These results, together with the thermodynamic data for Na_2O_2, were used to calculate the enthalpies and Gibbs energies of formation of melt compositions between $NaO_{1.0}$ and $NaO_{0.5}$. However, there are no numerical results reported. Therefore these data are not used for evaluation.

The enthalpy of formation at 298.15 K is adopted as $-122.66 \pm 1.2\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

The low temperature heat capacities, 52.31-296.22 K, were measured by Todd (7). His sample contains (percent) 94 $Na_2O_2(cr)$, 3.6 $Na_2O(cr)$ and 2.4 Na_2CO_3. Corrections in the reported results have been made for Na_2CO_3 content, but not for Na_2O content which was estimated to be small. The $C_p°$ values below 52.31 K are calculated using the equation $C_p° = D(252/T)+3E(399/T)$ reported by Todd. $S°(298.15\ K)$ is derived from the adopted $C_p°$, based on $S°(50\ K) = 1.012\ cal\ K^{-1}\ mol^{-1}$.

The high temperature enthalpies, 375.4-869.2 K, were determined by Chandrasekharaiah (8), using drop calorimetry. Corrections were made for the contributions from impurities (Na_2CO_3, 1.5 and Na_2O, 0.2%). A discontinuity was observed in the enthalpies between 773 and 793 K, indicating some kind of transition (see Transition Data). The $C_p°$ for $Na_2O_2(\alpha)$ at temperatures 298-769.5 K are derived from the enthalpy measurements, 375.4-769.5 K, and joined smoothly with the low temperature data at 298.15 K, and extrapolated to 785 K(T_{trs}). The $C_p°$ for $Na_2O_2(\beta)$ is derived from the enthalpy data, 794-869.2 K, as constant, 27.15 cal $K^{-1}\ mol^{-1}$, and extrapolated to 2500 K.

Vedeneev (9) measured the high temperature specific heat of $Na_2O_2(cr)$ in the temperature interval 292-373 K using adiabatic calorimetry. The reported average value, 21.46 cal $K^{-1}\ mol^{-1}$, is in fair agreement with the adopted ones.

Transition Data

T_{trs} was reported by Tallman (10), who measured the X-ray power diffraction pattern by a Geiger-counter diffractometer and found that at about 510°C the pattern changes entirely and a new set of peaks indicates a new phase. Separate thermal analysis measurements (10) confirm the transition temperature ($\alpha \rightarrow \beta$) is 512 ± 1°C or 785 ± 1 K, which is adopted here. Foppl (11) found a thermal anomaly at 485°C in both heating and cooling curves. $\Delta_{trs}H°$ is derived from the adopted enthalpy and $C_p°$ data on $Na_2O_2(\alpha)$ and $Na_2O_2(\beta)$.

Fusion Data

T_{fus} is obtained from Bunzel (12). T_{fus} = 733 and 783 K were reported by Blumenthal (13) and Rode (14), respectively, which are not adopted.

PREVIOUS: June 1963 CURRENT: June 1968

$S°(298.15\ K) = 113.847 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1362 \pm 0.5\ K$

$\Delta_f H°(0\ K) = -1551.20 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1561.43 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 51.798\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpies of solution of NaCl(cr), Na_2SO_4(cr), SiO_2(quartz), Na_2SiO_3(cr), HCl(aq) and H_2SO_4(aq) in 20% hydrofluoric acid at 74.7°C were measured by Kracek (1). The author derived two values of $\Delta_{sln}H°$ of Na_2O(cr) from those of NaCl(cr), Na_2SO_4(cr), HCl(aq) and H_2SO_4(aq) presumably employing auxiliary data from (2). We recalculate $\Delta_{sln}H°$ of Na_2O(cr) in the calorimetric solution as -87.50 (chloride scheme, originally -87.66) and -88.74 kcal mol^{-1} (sulfate scheme, originally -89.19), using recent $\Delta_f H°(298.15\ K)$ values for NaCl(cr), Na_2SO_4(cr), HCl(aq), H_2SO_4(aq), and Na_2O(cr). The corresponding enthalpy changes, $\Delta_r H°(298.15\ K)$, for the reaction $Na_2O(cr) + SiO_2(quartz) = Na_2SiO_3(cr)$ are derived as -55.20 and -56.38 kcal mol^{-1}. Adopting the weighted average $\Delta_r H°(298.15\ K) = -55.59$ kcal mol^{-1} with $\Delta_f H°(Na_2O, cr, 298.15\ K) = -99.9$ kcal mol^{-1} and $\Delta_f H°(SiO_2, quartz, 298.15\ K) = -217.7$ kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K) = -373.19$ kcal mol^{-1} for Na_2SiO_3(cr). This $\Delta_f H°(Na_2SiO_3, cr, 298.15\ K)$ value is independent of future changes in $\Delta_f H°(298.15\ K)$ of Na_2O(cr) but the values of $\Delta_{sln}H°$ and $\Delta_r H°$ are not independent. The adopted value of $\Delta_f H°(Na_2, cr, 298.15\ K)$ is the average of -100.1 and -99.7 kcal mol^{-1} reported by Roth and Kaule (3) and Matsui and Oka (4), respectively.

Roth and Troitzsch (5) have measured the enthalpies of solution of SiO_2(quartz), Na_2SiO_3(cr) and Na_2O(cr) in 10.3% HF at 22°C to be -32.85, -67.96 and -89.9 kcal mol^{-1}, respectively. Using these results, we calculate the enthalpy change of the reaction $Na_2O(cr) + SiO_2(quartz) = Na_2SiO_3(cr)$ as -53.79 kcal mol^{-1} and $\Delta_f H°(Na_2SiO_3, cr, 298.15\ K) = -371.39$ kcal mol^{-1}.

By use of high temperature reaction calorimetry, Kroger and Janetzko (6) have determined the enthalpy change of the reaction $Na_2C_3(cr) + Na_2Si_2O_5(g, \ell) = 2\ Na_2SiO_3(cr) + CO_2(g)$ as 17.99 kcal mol^{-1}. Based on $\Delta_f H°(298.15\ K) = -270.26$, -582.92 and -94.05 kcal mol^{-1} for Na_2SiO_3(cr).

The enthalpies of solution of Na_2CO_3(cr), SiO_2(quartz) and Na_2SiO_3(cr) in 39% HF at 26.5°C were measured to be -244.1, -564.5 and -673.6 cal g^{-1} by Hummel and Schwiete (7). From these results we calculate the enthalpy change to be 22.43 kcal mol^{-1} for the reaction $Na_2CO_3(cr) + SiO_2(quartz) = Na_2SiO_3(cr) + CO_2(g)$, yielding $\Delta_f H°(Na_2SiO_3, cr, 298.15\ K) = -371.48$ kcal mol^{-1}.

Many other older calorimetric measurements have been made in order to derive the enthalpies of formation for Na_2SiO_2(cr), but most of these are of questionable accuracy and in some cases the products of the reaction are uncertain. For further details, see the review by McCready (8).

Heat Capacity and Entropy

The low temperature heat capacities, 53.6 - 294.5 K, were measured by Kelley (9), and high temperature enthalpies, 360.5 - 1747 K were determined by Naylor (10). The high temperature heat capacities are derived from the measured enthalpy data and joined smoothly with the low temperature $C°_p$ values. The entropy at 298.15 K is calculated using the adopted low temperature heat capacities, based on S°(50 K) = 1.195 cal K^{-1} mol^{-1}.

Fusion Data

See the liquid table for details.

SODIUM SILICATE (Na_2SiO_3) LIQUID M_r = 122.06324

$S°(298.15\ K) = [150.496]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1362 \pm 0.5\ K$

$\Delta_f H°(298.15\ K) = [-1510.875]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 51.798\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Na_2SiO_3, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Na_2SiO_3, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1362\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity above 900 K is derived as constant from the high temperature enthalpy data, 1414 - 1747 K, measured by Naylor (1). *A glass transition temperature is assumed at 900 K, i.e., the heat capacities below 900 K are taken to be those for* $Na_2SiO_3(cr)$.

$S°(\ell, 298.15\ K)$ is calculated in a manner analogous to that used for the enthalpy of formation. The low temperature heat capacities, 63.74 -162.48 K, have been measured by Tarasov and Savitskaya (2); however, these are not adequate to be used to evaluate $S°(298.15\ K)$.

Fusion Data

The adopted T_{fus} = 1362 K, determined by Kracek (3), is in good agreement with the value 1261 K reported by Jaeger (4) and later confirmed by Morey and Bowen (5).

Other reported T_{fus} values are 1280, 1291, and 1329 K by Kultascheff (6), Wallace (7) and van Klooster (8), respectively. These values are all lower than the adopted T_{fus} value, probably because the sample compositions were not the exact composition of metasilicate.

The value of $\Delta_{fus} H°$ is evaluated from the adopted heat capacities for $Na_2SiO_3(cr)$ and $Na_2SiO_3(\ell)$, and the enthalpy data reported by Naylor (1), assuming the final state of the calorimetric sample to be $Na_2SiO_3(cr)$. From the phase diagrams of Na_2SiO_3 with other compounds, Kelley (9) derived the values of $\Delta_{fus} H°$ of 9.8 - 10.5 kcal mol^{-1}.

$S°(298.15\ K) = [163.212]\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(I \rightarrow \delta) = [986]\ K$

$T_{fus}(\delta \rightarrow \ell) = [1170]\ K$

$\Delta_f H°(298.15\ K) = [-1379.294]\ kJ\ mol^{-1}$

$\Delta_{trs} H°(I \rightarrow \delta) = [0.502]\ kJ\ mol^{-1}$

$\Delta_{fus} H°(\delta \rightarrow \ell) = [21.338]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation adopted in this tabulation is obtained from $\Delta_f H°(298.15\ K)$ for Na_2SO_4(cr, I) by adding $\Delta_{trs} H°(I \rightarrow \delta)$ and the difference between H°(986 K)-H°(298.15 K) for Na_2SO_4(cr, I) and Na_2SO_4(cr, δ) (2).

Heat Capacity and Entropy

Heat capacities in the range 900 - 1010 K were measured by Shmidt and Sokolov (1) in an adiabatic calorimeter. We have graphically extrapolated these data down to 298.15 K, paralleling the $C_p°$ data of Na_2SO_4(cr, I), and extended the data smoothly to 1500 K. Our calculated enthalpies are biased by some 300 cal $K^{-1}\ mol^{-1}$ above the experimental results (for the I phase) of Denielou et al. (3) and Coughlin (4). See the discussion in the Na_2SO_4(cr, I) table (2).

Transition Data

The existence of Na_2SO_4(cr, δ) is based on the work of Shmidt and Sokolov (1) who found an anomolous region in the heat capacity curve of Na_2SO_4(cr, I) between 963 - 993 K. Popov and Ginzburg (5) also observed a sharp change in the heat capacity above 837.6 K. Simanov and Kirkina (6) have observed an orthorhombic modification of Na_2SO_4 at 993 K by X-ray diffraction. As noted above, our calculated enthalpies do not agree with measured enthalpies above 980 K. The evidence for the existence of the δ-phase is not conclusive. We have deleted the δ-phase from our combined phase table for Na_2SO_4. The heat of transition $\Delta_{trs} H°(I \rightarrow \delta, 986\ K) = 120 \pm 10$ cal mol^{-1} is obtained by graphical integration of the area between the measured $C_p°$ curve from (1) and the adopted $C_p°$ curve for Na_2SO_4(cr, I) (2). The temperature of the transition is assumed to be 986 K.

Fusion Data

Based on our selected $C_p°$ values for Na_2SO_4(cr, δ) and Na_2SO_4(ℓ), we derive $\Delta_{fus} H°(\delta \rightarrow \ell) = 5.10 \pm 0.10$ kcal mol^{-1} using the experimental liquid enthalpies from Denielou et al. (3) and Coughlin (4). $T_{fus}(\delta \rightarrow \ell) = 1170$ K is the calculated temperature at which $\Delta_r G° = 0$ for Na_2SO_4(cr, δ) → Na_2SO_4(ℓ).

PREVIOUS: December 1966 CURRENT: June 1978

$S°(298.15\ K) = [160.132 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$
$T_{trs}(III \rightarrow I) = 509 \pm 1\ K$
$T_{trs}(IV \rightarrow I) = 514 \pm 1\ K$
$T_{fus}(I \rightarrow \ell) = 1157 \pm 1\ K$

$\Delta_f H°(298.15\ K) = [-1380.899 \pm 0.8]\ kJ\ mol^{-1}$
$\Delta_{trs}H°(III \rightarrow I) = 6.887 \pm 0.084\ kJ\ mol^{-1}$
$\Delta_{trs}H°(IV \rightarrow I) = 10.908 \pm 0.084\ kJ\ mol^{-1}$
$\Delta_{fus}H°(I \rightarrow \ell) = 23.849 \pm 0.42\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation adopted in this tabulation is obtained from $\Delta_f H°(Na_2SO_4, cr, III, 298.15\ K)$ by adding $\Delta_{trs}H°(III \rightarrow I, 509\ K) = 1646\ cal\ K^{-1}\ mol^{-1}$ (1, 2) and the difference between H°(509 K)-H°(298.15 K) for Na_2SO_4(cr, III) and Na_2SO_4(cr, I) (2).

Heat Capacity and Entropy

Heat capacities of Na_2SO_4(cr, I) have been measured by Shmidt and Sokolov (3) in an adiabatic calorimeter over the temperature range 538.65 - 1021.75 K. The direct heating measurements of Popov and Galchenko (4) using a heat-flow calorimeter are in substantial agreement. Enthalpy measurements by drop calorimetry have been carried out by Coughlin (5, 515 - 1143 K), Popov and Ginzburg (6, 1173 - 1290 K), May (7, 520 - 1157 K), and by Denielou et al. (8, 516 - 1154 K).

The data of May (7) are not in agreement with the other enthalpy results. The enthalpy data of references (5, 6, 8) are in general agreement but our derived $C_p°$ values are lower than the calorimetric $C_p°$ (3) results below 800 K but show the proper slope. Derived $C_p°$ values from Denielou et al. (8) are in agreement with the calorimetric results above 930 K. All of the experiments seem to show a change in the slope of the $C_p°$ curve near 900 K. We adopt $C_p°$ from 530 - 880 K from (3) and extrapolate smoothly to 1500 K. $C_p°$ values below 530 K are obtained by graphical extrapolation. The entropy, S°(298.15 K), is calculated in a manner analogous to that of the heat of formation.

Transition Data

Na_2SO_4(cr, I) is the hexagonal modification (space group D_{3d}^3 or C3ml (9, 10)) of anhydrous sodium sulfate stable from 514 - 1157 K. All the low-temperature modifications (III, IV, V) are converted to the high temperature form between 500 - 530 K (2); $\Delta_{trs}H°(IV \rightarrow I, 514\ K) = 2607\ cal\ mol^{-1}$ (1, 2), $\Delta_{trs}H°(V \rightarrow I, 512\ K) = 2663\ cal\ mol^{-1}$ (1, 2), and $\Delta_{trs}H°(III \rightarrow I, 509\ K) = 1646\ cal\ mol^{-1}$ (1, 2).

A small anomalous region between 963.15 - 993.15 K on the $C_p°$ curve for Na_2SO_4(cr, I) was reported by Shmidt and Sokolov (3), who attributed the anomaly to a transition to another phase of Na_2SO_4 which they referred to as the δ-phase. There is not sufficient evidence to warrant our inclusion of the δ-phase.

Fusion Data

The enthalpy of melting of $Na_2SO_4(cr, I) \rightarrow Na_2SO_4(\ell)$ has been derived from drop calorimetry data by Denielou et al. (8, 5.58 ± 0.13 kcal mol^{-1}), Coughlin (5, 5.67 ± 0.1 kcal mol^{-1}), Popov and Ginzburg (6, 5.77 ± 0.2 kcal mol^{-1}), and May (7, 5.8 ± 0.2 kcal mol^{-1}). No mention was made of the δ phase. Based on our selected $C_p°$ values for $Na_2SO_4(cr, \ell)$ and $Na_2SO_4(\ell)$, we derive $\Delta_{fus}H°(I \rightarrow \ell) = 5.70 \pm 0.10\ kcal\ mol^{-1}$, using the enthalpy data of Coughlin (5). There is good agreement on the melting temperature which we take as $T_{fus}(I \rightarrow \ell) = 1157 \pm 1\ K$.

PREVIOUS: December 1966 CURRENT: June 1978

$S°(298.15\ K) = 154.908 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(III \rightarrow I) = 509 \pm 1\ K$

$\Delta_f H°(0\ K) = -1373.71 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1384.85 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_{trs} H°(III \rightarrow I) = 6.887 \pm 0.084\ kJ\ mol^{-1}$

Enthalpy of Formation

Brodale and Giauque (1) determined the enthalpy of solution at infinite dilution $\Delta_{sln}H°(Na_2SO_4, cr, III, 298.15\ K) = -1273 \pm 4\ cal\ K^{-1}\ mol^{-1}$ for the process $Na_2SO_4(cr, III) + Na_2SO_4(aq, \infty)$. When this result is combined with the enthalpies of formation of the infinitely dilute ions from CODATA (2), we obtain $\Delta_f H°(Na_2SO_4, aq, \infty, 298.15\ K) = -332.266 \pm 0.13\ kcal\ mol^{-1}$ and $\Delta_f H°(Na_2SO_4, cr, III, 298.15\ K) = -330.993 \pm 0.15\ kcal\ mol^{-1}$. Coughlin (3) also measured the enthalpy of solution, $\Delta_{sln}H°(Na_2SO_4, cr, III, 303\ K) = -1363 \pm 4\ cal\ K^{-1}\ mol^{-1}$ for the process $Na_2SO_4(cr, III) + Na_2SO_4(aq, 1068\ H_2O)$. Using $\Delta C°_p$ as determined by Coughlin to extrapolate the heat of solution to 298 K gives $\Delta_{sln}H°(Na_2SO_4, cr, III, 298.15\ K) = -1037 \pm 20\ cal\ K^{-1}\ mol^{-1}$. Extrapolating to infinite dilution using the data of Lange and Streeck (4) and Wallace and Robinson (5) gives $\Delta_{sln}H°(Na_2SO_4, cr, III, 298.15\ K) = -1282 \pm 20\ cal\ K^{-1}\ mol^{-1}$. Using the same auxiliary data as above (2) $\Delta_f H°(Na_2SO_4, cr, III, 298.15\ K) = -330.984 \pm 0.15\ kcal\ mol^{-1}$. The enthalpy of solution data of Coughlin (3) as corrected by Brodale and Giauque (1) leads to $\Delta_r H°(V \rightarrow III, 298.15\ K) = 716 \pm 8\ cal\ K^{-1}\ mol^{-1}$. When this is combined with auxiliary data for $Na_2SO_4(cr, V)$ (8), we obtain $\Delta_f H°(Na_2SO_4, cr, III, 298.15\ K) = -330.980 \pm 0.2\ kcal\ mol^{-1}$. We adopt an intermediate value $\Delta_f H°(Na_2SO_4, cr, III, 298.15\ K) = -330.988 \pm 0.15\ kcal\ mol^{-1}$ for this tabulation.

Heat Capacity and Entropy

Heat capacities of Na_2SO_4(cr, III) have been measured by Brodale and Giauque (1) over the ragne 13.16 - 297.71 K and by Shmidt and Sokolov (7) in an adiabatic calorimeter over the temperature range 319.03 - 520.56 K. Paukov and Lavrent'eva (8) also measured the low temperature heat capacity of Na_2SO_4(cr, III) but their results are intermediate between Na_2SO_4(cr, V) and Na_2SO_4(cr, III) indicating that their sample may have been converted to as much as two-thirds of the V modification. Coughlin (3) measured enthalpies of Na_2SO_4(cr, III) from 370.2 - 514.9 K by drop calorimetry, but his data appear high by 2% at 450 K. Enthalpy measurements of Denielou et al. (9) are in very good agreement with the $C°_p$ measurements of Shmidt and Sokolov (7). We combine the three sets of experimental data (1, 7, 9) by graphical smoothing and by fitting the data with orthogonal polynomials over selected overlapping temperature intervals. $C°_p$ is smoothly extrapolated to 1000 K. S°(298.15 K) is derived from our combined smooth fit based on $S°(14\ K) = 0.100\ cal\ K^{-1}\ mol^{-1}$ and $H°(14\ K)-H°(0\ K) = 1.051\ cal\ K^{-1}\ mol^{-1}$ derived from a Debye T^3-law extrapolation.

Transition Data

Na_2SO_4(cr, III) is the meltable low-temperature orthorhombic modification of anhydrous sodium sulfate which is obtained on cooling, in the absence of moisture, the high-temperature hexagonal form Na_2SO_4(cr, I). Na_2SO_4(cr, III) is metastable with respect to the two other low-temperature orthorhombic forms Na_2SO_4(cr, V) and Na_2SO_4(cr, IV). The space group of Na_2SO_4(cr, III) has been given as *Cmcm* (10).

The second-order transformation from Na_2SO_4(cr, III) to Na_2SO_4(cr, I) in which both phases are metastable, has been observed by Shmidt and Sokolov (7) at 521.5 K, $\Delta_{trs}H°(III \rightarrow I) = 1642 \pm 20\ cal\ mol^{-1}$; by Coughlin (3) at 514 K, $\Delta_{trs}H°(III \rightarrow I) = 1680\ cal\ mol^{-1}$, by Denielou et al. (9) at 515 ± 1 K, $\Delta_{trs}H°(III \rightarrow I) = 1650 \pm 90\ cal\ mol^{-1}$; and by May (11) at 520 ± 5 K, $\Delta_{trs}H°(III \rightarrow I) = 1150\ cal\ mol^{-1}$. We adopt the transition temperature from the analysis of Brodale and Giauque (1). This is consistent with our analysis which yields $\Delta_{trs}H°(III \rightarrow I, 298.15\ K) = 1646 \pm 20\ cal\ mol^{-1}$. The heat of transition from metastable Na_2SO_4(cr, V) to metastable Na_2SO_4(cr, III) has been measured by heat of solution measurements on the separate crystalline forms by Coughlin (3), Brodale and Giauque (1) and Pickering (12). $\Delta_r H°(V \rightarrow III, 298.15\ K) = 716 \pm 8\ cal\ mol^{-1}$ (1, 3), $699 \pm 10\ cal\ mol^{-1}$ (1), $709 \pm 10\ cal\ mol^{-1}$ (1, 13) and $\Delta_r H°(V \rightarrow III, 294\ K) = 708 \pm 20\ cal\ mol^{-1}$ (12). Using the heat of transition value from (1) and the difference between H°(517 K)-H°(298.15 K) for Na_2SO_4(cr, III) and Na_2SO_4(cr, V) (6), we obtain $\Delta_{trs}H°(V \rightarrow III, 517\ K) = 1041 \pm 20\ cal\ mol^{-1}$. The heat of transition from metastable Na_2SO_4(cr, IV) to metastable Na_2SO_4(cr, III) is discussed on the table for Na_2SO_4(cr, IV). Our analysis yields $\Delta_{trs}H°(IV \rightarrow III, 519\ K) = 988 \pm 20\ cal\ mol^{-1}$.

$S°(298.15\ K) = [150.157 \pm 0.4]\ J\ K^{-1}\ mol^{-1}$
$T_{trs}(V \rightarrow IV) = 458 \pm 1\ K$
$T_{trs}(IV \rightarrow I) = 514 \pm 1\ K$

$\Delta_f H°(0\ K) = [-1380.09]\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1387.559 \pm 0.63\ kJ\ mol^{-1}$
$\Delta_{trs}H°(V \rightarrow IV) = 0.255 \pm 0.063\ kJ\ mol^{-1}$
$\Delta_{trs}H°(IV \rightarrow I) = 10.908 \pm 0.084\ kJ\ mol^{-1}$

Enthalpy of Formation

Brodale and Giauque (1) determined the enthalpy of solution at infinite dilution $\Delta_{sln}H°(Na_2SO_4, cr, IV, 298.15\ K) = -635 \pm 1$ kcal mol^{-1} for the process $Na_2SO_4(cr, IV) \rightarrow Na_2SO_4(aq, \infty)$. When this result is combined with the enthalpies of formation of the *infinitely dilute ions from CODATA* (2), *we obtain* $\Delta_f H°(Na_2SO_4, aq, \infty, 298.15\ K) = -332.266 \pm 0.13$ kcal mol^{-1} and $\Delta_f H°(Na_2SO_4, cr, IV, 298.15\ K) = -331.631 \pm 0.15$ kcal mol^{-1}. Brodale and Giauque (1) have also determined the difference in $\Delta_f H°(298.15\ K)$ between Na_2SO_4(cr, IV) and Na_2SO_4(cr, V) by direct heat of solution experiments. We prefer to give complete weight to these results using the same calorimeter. $\Delta_{sln}H°(Na_2SO_4, cr, V, 298.15\ K) = -574$ cal K^{-1} mol^{-1} (1) which leads to $\Delta_r H°(V \rightarrow IV, 298.15\ K) = 61 \pm 15$ cal K^{-1} mol^{-1}. When this is combined with auxiliary data for Na_2SO_4(cr, V) (3), we obtain $\Delta_f H°(Na_2SO_4, cr, IV, 298.15\ K) = -331.635 \pm 0.15$ kcal mol^{-1}. This value of $\Delta_f H°(298.15\ K)$ is adopted in this tabulation.

Heat Capacity and Entropy

The heat capacity of Na_2SO_4(cr, IV) has been taken equal to the heat capacity of the V form from 298-514 K (1, 3). The heat of transition (V → IV) adopted here leads to a calculated entropy of transition of 0.133 cal K^{-1} mol^{-1} and $S°(Na_2SO_4, cr, IV, 458\ K) = 50.304$ cal K^{-1} mol^{-1}. Brodale and Giauque (1) state that the small difference in entropy (between IV and V) means that on the average the heat capacity of Na_2SO_4(cr, IV) should exceed the heat capacity of Na_2SO_4(cr, V) by only about 0.3% over the range 298-514 K. We calculate $S°(Na_2SO_4, cr, IV, 298.15\ K) = 35.887$ cal K^{-1} mol^{-1}.

Transition Data

Na_2SO_4(cr, IV) is the orthorhombic modification of anhydrous sodium sulfate stable from 458-514 K (1, 4). This form can persist down to low temperatures. The presence of moisture enhances the achievement of equilibrium. A recent Raman and DSC study has failed to observe the IV modification (8). The (V → IV) transition at 458 K has been discussed previously (see (3) and above), $\Delta_r H°(V \rightarrow IV, 298.15\ K) = 61 \pm 15$ cal mol^{-1}. Since $\Delta C_p° = 0$ (1, 3), $\Delta_{trs}H°(V \rightarrow IV, 458\ K) = 61 \pm 15$ cal mol^{-1}. The temperature of 458 K for the transition is taken from Kracek (4) and Brodale and Giauque (1).

The transition from Na_2SO_4(cr, IV) to Na_2SO_4(cr, I) has been found to occur at 514 K (1, 4). The heat of the transition has not been directly measured although Shmidt and Sokolov (5) obtained $\Delta_{trs}H°(516\ K) = 2584 \pm 15$ cal mol^{-1} for a sample of ground Na_2SO_4 which could have been Na_2SO_4(cr, IV) (see 1). We adopt the value of the heat of transition $\Delta_{trs}H°(IV \rightarrow I, 514\ K) = 2607 \pm 20$ cal mol^{-1}. This is obtained by summation of $\Delta_{trs}H°(IV \rightarrow III)$ (1, 3) and $\Delta_{trs}H°(III \rightarrow I)$ (1, 3), all reduced to 514 K. Other measurements include that of Kreidl and Simon (6) who found $\Delta_{trs}H°(IV \rightarrow I, 511\ K) = 2300$ cal mol^{-1} and Popov and Galchenko (7) who found $\Delta_{trs}H°(518\ K) = 2586 \pm 64$ cal mol^{-1} on first heating. Later heating apparently converted some sample over to the III modification. Brodale and Giauque (1) give $\Delta_{trs}H°(IV \rightarrow I, 514\ K) = 2611$ cal mol^{-1}.

The heat of transition from metastable Na_2SO_4(cr, IV) to metastable Na_2SO_4(cr, III) is obtained from heat of solution measurements on the separate crystalline forms. Brodale and Giauque (1) obtained $\Delta_{sln}H°(Na_2SO_4, cr, IV, 298.15\ K) = -635 \pm 1$ cal mol^{-1} and $\Delta_{sln}H°(Na_2SO_4, cr, III, 298.15\ K) = -1273 \pm 4$ cal mol^{-1} from which $\Delta_r H°(IV \rightarrow III, 298.15\ K) = 638 \pm 10$ cal mol^{-1}. Combining this result with the difference between H°(519 K)-H°(298.15 K) for Na_2SO_4(cr, IV) and Na_2SO_4(cr, III) we obtain $\Delta_{trs}H°(IV \rightarrow III, 519\ K) = 988 \pm 20$ cal mol^{-1}. Shmidt and Sokolov (5) have measured the heats of transformation of Na_2SO_4(thenardite) → Na_2SO_4,cr, I) and Na_2SO_4(cr, III) → Na_2SO_4(cr, I) calorimetrically from which we obtain $\Delta_{trs}H°$(thenardite → III, 516 K) = 954 ± 20 cal mol^{-1}. Brodale and Giauque (1) have speculated that the "ground thenardite" of (5) was actually the IV modification of Na_2SO_4.

PREVIOUS: CURRENT: June 1978

$S°(298.15\ K) = 149.595 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(V \rightarrow IV) = 458 \pm 1\ K$

$\Delta_f H°(0\ K) = -1376.361 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1387.816 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_{trs} H°(V \rightarrow IV) = 0.255 \pm 0.063\ kJ\ mol^{-1}$

Enthalpy of Formation

Shibata et al. (1) measured the emf of the cell: Na(amalgam, 0.2077%)|Na_2SO_4(sat. soln), Hg_2SO_4|Hg at 306-310 K. Extrapolating their results to 298 K, correcting the observed voltage for the formation of the Na-amalgam, and converting to absolute volts, we have E_{cell} = 3.33404 volts for the reaction at 298 K, 2 Na(cr) + Hg_2SO_4(cr) = 2 Hg(ℓ) + Na_2SO_4(cr, V). From this voltage we calculate $\Delta_r G°(298.15\ K) = -153.77\ kcal\ mol^{-1}$. Taking $\Delta_f G°(Hg_2SO_4, cr, 298.15\ K) = -149.66\ kcal\ mol^{-1}$ (2) and reference entropies from (3), we calculate $\Delta_f G°(Na_2SO_4, cr, V, 298.15\ K) = -303.43\ kcal\ mol^{-1}$ and $\Delta_f H°(Na_2SO_4, cr, V, 298.15\ K) = -331.60 \pm 0.2\ kcal\ mol^{-1}$.

The enthalpy of solution at infinite dilution, $\Delta_{sln} H°(Na_2SO_4, cr, V, 298.15\ K) = -570 \pm 10\ cal\ K^{-1}\ mol^{-1}$ adopted in this tabulation is based on our reanalysis of the enthalpy of solution measurements of Gardner et al. (4), Brodale and Giauque (5), Pitzer and Coulter (6), Coughlin (7) as corrected in (5), and Readnour and Cobble (8). When this result is combined with heats of formation of the infinitely dilute ions from CODATA (2), we obtain $\Delta_f H°(Na_2SO_4, aq, \infty, 298.15\ K) = -332.266 \pm 0.13\ kcal\ mol^{-1}$ and $\Delta_f H°(Na_2SO_4, cr, V, 298.15\ K) = -331.696 \pm 0.15\ kcal\ mol^{-1}$. The experimental $\Delta_{sln} H°$ values and the number of determinations are $-582 \pm 5\ cal\ K^{-1}\ mol^{-1}$, 6 (4), $-574\ cal\ K^{-1}\ mol^{-1}$, 1 (5), $-564 \pm 10\ cal\ K^{-1}\ mol^{-1}$, 2 (6), $-565 \pm 30\ cal\ K^{-1}\ mol^{-1}$, 5 (7, 5), and $-567 \pm 12\ cal\ K^{-1}\ mol^{-1}$, 9 (8).

We adopt $\Delta_f H°(Na_2SO_4, cr, V, 298.15\ K) = -331.696 \pm 0.5\ kcal\ mol^{-1}$ from the heat of solution results for consistency with the other modifications of Na_2SO_4(cr) (3).

Heat Capacity and Entropy

Heat capacities of Na_2SO_4(cr, V) have been measured by Pitzer and Coulter (6) over the range 13.74-313.44 K and by Shmidt and Sokolov (9) in an adiabatic calorimeter over the temperature range 324.62-503.06 K. Shmidt (10) later carried out additional measurements which he combined with the earlier measurements of Shmidt and Sokolov (9) and reported $C°_p$ values extending from 298.5-503.1 K. We have smoothed the experimental data (6, 9, 10) by fitting the data with orthogonal polynomials over selected overlapping temperature intervals. The data have been smoothly extrapolated to 1000 K. We have given no weight to the calorimetry enthalpy differences measured by Coughlin (7), May (11), and Denielou et al. (12). These measured enthalpies are higher than our calculated enthalpies by 6%, 9% and 2%, respectively at 400 K. The $C°_p$ measurements of Popov and Galchenko (13) from 373-468 K appear to be biased, being too low at 373 K and too high at 468 K. S°(298.15 K) is derived from our combined smooth fit based on S°(14 K) = 0.059 cal K^{-1} mol^{-1} and H°(14 K)-H°(0 K) = 0.620 cal mol^{-1} derived from a T^3-law extrapolation.

Transition Data

Na_2SO_4(cr, V) is the stable low-temperature modification of anhydrous sodium sulfate which is obtained by crystallization from aqueous solution above 305.65 K under ordinary pressure. The mineral is known as thenardite and exists in the form of orthorhombic crystals (space group Fddd) (15).

Polymorphism studies by Kracek (14) indicated five distinct modifications of anhydrous sodium sulfate, i.e., V, IV, III, II, I. Calorimetric studies by Shmidt and Sokolov (9) as well as the X-ray work of Simanov and Kirkina (15) suggested another form, stable at high temperatures which is labeled as Δ. Brodale and Giauque (5) have recently reviewed the relationships among the various crystalline forms of Na_2SO_4(cr). Their analysis shows that Na_2SO_4(cr, V) is the stable form from 0 to 458 K; Na_2SO_4(cr, IV) rather than Na_2SO_4 (cr, III) is the stable form from 458 to 514 K; Na_2SO_4(cr, I) is the form stable from 514 K to the melting point. Na_2SO_4(cr, III) is metastable at all temperatures from 0 to 517 K. Na_2SO_4(cr, II) is a meta-stable phase intermediate between forms III and I. The phase transitions are sluggish and subject to hysteresis. Forms V, IV and III can all persist far beyond their stable regions.

The heat of transition $\Delta_{trs} H°(V \rightarrow IV, 458\ K) = 61 \pm 15\ cal\ mol^{-1}$ is discussed on the table for Na_2SO_4(cr, IV) (3). The temperature of the transition is taken from the work of Kracek (14) and Brodale and Giauque (5). The heat of transition from metastable Na_2SO_4(cr, V) to metastable Na_2SO_4(cr, III) $\Delta_{trs} H°(V \rightarrow III, 517\ K) = 1041 \pm 20\ cal\ mol^{-1}$ has been discussed on the table for Na_2SO_4(cr, III) (3). This compares to $\Delta_{trs} H°(V \rightarrow III, 521\ K) = 1030 \pm 25\ cal\ mol^{-1}$ from Shmidt and Sokolov (9) and $\Delta_{trs} H°(V \rightarrow III, 514\ K) = 1040 \pm 20\ cal\ mol^{-1}$ from (5). The heat of transition from metastable Na_2SO_4(cr, V) to metastable Na_2SO_4(cr, I) at 512 ± 1 K is obtained by summation of $\Delta_{trs} H°(V \rightarrow III) = 1021\ cal\ mol^{-1}$ and $\Delta_{trs} H°(III \rightarrow I) = 1642\ cal\ mol^{-1}$ (5) to yield $\Delta_{trs} H°(V \rightarrow I, 512\ K) = 2663 \pm 25\ cal\ mol^{-1}$, in good agreement with the value measured by Shmidt and Sokolov (9), $\Delta_{trs} H°(V \rightarrow I, 521\ K) = 2673 \pm 5\ cal\ mol^{-1}$. Brodale and Giauque (5) give $\Delta_{trs} H°(V \rightarrow I, 512\ K) = 2681 \pm 20\ cal\ mol^{-1}$.

PREVIOUS: December 1966 CURRENT: June 1978

$S°(298.15\ K) = [181.172]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}(I \rightarrow \ell) = 1157 \pm 1\ K$

$T_{dcm} = 2500\ K$

$\Delta_f H°(298.15\ K) = [-1356.385]\ kJ\ mol^{-1}$

$\Delta_{fus}H°(I \rightarrow \ell) = 238.49 \pm 0.42\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(Na_2SO_4, cr, I, 298.15\ K)$ by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1157\ K)-H°(298.15\ K)$, between $Na_2SO_4(cr, I)$ and $Na_2SO_4(\ell)$ (5).

Heat Capacity and Entropy

The enthalpies for $Na_2SO_4(\ell)$ have been measured by drop calorimetry in the temperature range 1164.7-1826.2 K by Coughlin (1), 1173.3-1502.6 K by Denielou (2), 1157-1500 K by May (3) and 1173.4-1290.2 K by Popov and Ginzburg (4). The more recent studies (1, 2, 4) are in very good agreement. The study of May (4) appears biased, being 1% low at 1200 K and 2% high at 1500 K. We have adopted heat capacities derived from the enthalpy data of Coughlin (1) over the range 1157-1800 K. The data have been extended to 800 K and 3000 K. Below an assumed glass transition temperature of 800 K, the heat capacities are taken to be identical to those of the I phase. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The enthalpy of melting of $Na_2SO_4(cr, I) \rightarrow Na_2SO_4(\ell)$ has been discussed in the $Na_2SO_4(cr, I)$ table (5). Kelley (6) had previously reported $\Delta_{fus}H°(1157\ K) = 5.83\ kcal\ mol^{-1}$ from data on binary systems. We prefer the results from direct calorimetric measurements.

Vaporization and Decomposition Data

Vaporization data on $Na_2SO_4(\ell)$ is discordant due primarily to the extent to which the vapor is dissociated. $Na_2SO_4(\ell)$ can decompose according to various mechanisms, the most significant of which is the reaction $Na_2SO_4(\ell) = 2\ Na(g) + SO_2(g) + O_2(g)$. Recent experimental data (7, 8, 9) are in good agreement with dissociation pressures and the heat of reaction calculated from the JANAF Thermochemical Tables (5). Decomposition to the oxides of sodium produces lower decomposition pressures than decomposition to the metal. In the presence of water vapor, significant decomposition can occur according to $Na_2SO_4(\ell) + H_2O(g) = 2\ NaOH(g) + SO_2(g) + 1/2\ O_2(g)$ (10). Molecular vaporization data are discussed in the $Na_2SO_4(g)$ table (5). $T_{dec} = 2500\ K$ is the calculated temperature at which the Gibbs energy difference is zero for the reaction $Na_2SO_4(\ell) = 2\ Na(g) + SO_2(g) + O_2(g)$.

Enthalpy of Formation

The adopted value of the enthalpy of formation, $\Delta_f H°(Na_2SO_4, g, 298.15\ K) = -247.04 \pm 6.0\ kcal\ mol^{-1}$, is based on JANAF analyses of the vaporization data given below. Early studies of the vaporization of sodium sulfate failed to take dissociation into account. The many of the effusion and transpiration results in the literature are in error. The dissociation is retarded in the presence of SO_2, O_2 mixtures as in the study of Cubicciotti and Kenesha (1) or in the presence of air (O_2) as in the study of Fryxell et al. (4). We have "corrected" some of the original data by subtracting the calculated dissociation pressures (15) from the total pressure to give molecular vaporization pressures. These "corrected data sets" are explicitly noted. Mass spectrometric experiments (2, 3, 5, and 14) can lead to direct molecular vaporization data provided the $Na_2SO_4^+$ ion is directly measured. Results from the Knudsen effusion experiments (5, 14) are in reasonable agreement with the most reliable transpiration experiments (1, 4). The calculated 3rd law $\Delta_r H°(298.15\ K)$ may have an uncertainty of 4 kcal mol^{-1} since the JANAF free energy functions are partially based on the estimated molecular constants of $Na_2SO_4(g)$. Vapor pressures from (1, 4 and 5) are in general agreement. Our adopted heat of formation is based on a weighted average of the 2nd or 3rd law results from (1, 4, 5, 14).

Heat Capacity and Entropy

The adopted structure (D_{2d} symmetry) is based on the similar symmetry assigned to $Cs_2SO_4(g)$ and to $K_2SO_4(g)$ in the high temperature electron diffraction studies of Ugarov et al. (6) and Spiridonov and Lutoshkin (7). This symmetry is supported by the IR and Raman study of Atkins and Gingerich (9) on Na_2SO_4 and K_2SO_4. The molecule can be pictured as having a central sulfur atom surrounded at the corners of a tetrahedron by four oxygen atoms with bridging sodium atoms between two pairs of oxygens. The internuclear distance of 1.48 Å for S-O is taken from data on other sulphates (6, 7, 8) while Na-O = 2.21 Å is an estimate from (7). The principal moments of inertia are $I_A = 15.518 \times 10^{-39}$ and $I_B = I_C = 71.418 \times 10^{-39}\ g\ cm^2$.

Atkins and Gingerich (9) have observed the infrared and Raman spectra of Na_2SO_4 and K_2SO_4 isolated in oxygen and nitrogen matrices at 12 K. Five of the eleven fundamental frequencies were observed in this work. The two other sulphate-ion group fundamentals are estimates taken from Gurvich et al. (10). The four fundamentals involving the metal atoms are based on the Raman single-crystal study of Montero (11) and comparisons involving K_2SO_4, Cs_2SO_4 (10), LiO_2 and NaO_2 (12). Uncertainties in the estimates of the gas phase frequencies may contribute an uncertainty of 4 cal K^{-1} mol^{-1} to S°(298.15 K).

$S°(298.15\ K) = 160.331 \pm 2.1\ J\ K^{-1}\ mol^{-1}$
$T_{trs1} = 862.0\ K$
$T_{trs2} = 860.8\ K$
$T_{fus} = 968.7\ K$

$\Delta_f H°(0\ K) = -1534.79 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1544.73 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_{trs1} H° = 4.113\ kJ\ mol^{-1}$
$\Delta_{trs2} H° = 30.849\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 23.799\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation, $\Delta_f H°(Na_2WO_4, cr, 298.15\ K) = -369.2\ kcal\ mol^{-1}$, is calculated from $\Delta_r H°(303.15\ K) = 19.44 \pm 0.08\ kcal\ mol^{-1}$ for the reaction of $H_2WO_4(cr) + 2\ NaCl(cr) = Na_2WO_4(cr) + 2\ HCl(aq, 12.731\ H_2O)$, using the JANAF value of $\Delta_f H°(H_2WO_4, cr, 298.15\ K) = -270.5\ kcal\ mol^{-1}$ and $\Delta_f H°(NaCl, cr, 298.15\ K) = -98.26\ kcal\ mol^{-1}$, and auxiliary data for HCl(aq) (11). The value of $\Delta_r H°(303.15\ K)$ was determined by solution calorimetry by Koehler et al. (1).

Sherfey and Brenner (2) measured by electrochemical calorimetry the enthalpy of reaction $\Delta_r H°(298.15\ K) = -7 \pm 1.5\ kcal\ mol^{-1}$ for $W(cr) + 2\ NaOH(aq, 55.55\ H_2O) + 2\ H_2O(\ell) = Na_2WO_4(aq, \infty) + 3\ H_2(g)$. This value, combined with the heat of solution (1, 3, 9), $\Delta_{sln} H° = 1.7 \pm 0.1\ kcal\ mol^{-1}$ for $Na_2WO_4(cr) = Na_2WO_4(aq, \infty)$, gives $\Delta_f H°(298.15\ K)\ (Na_2WO_4, cr) = -368.4\ kcal\ mol^{-1}$, which is in good agreement with the value adopted.

The previously accepted value (1, 3), $\Delta_f H°(Na_2WO_4, cr, 298.15\ K) = -379 \pm 0.5\ kcal\ mol^{-1}$, was based on the unreliable $\Delta_f H°(H_2WO_4, cr, 298.15\ K) = -280.2 \pm 0.4\ kcal\ mol^{-1}$. (See JANAF H_2WO_4, cr, table of March 31, 1967.) The other quoted value (4), $\Delta_f H°(Na_2WO_4, cr, 298.15\ K) = -395\ kcal\ mol^{-1}$, was obtained from Mixter's (5) measurement of the heat of reaction of tungsten powder with excess Na_2O_2. This value was probably in error because the complex tungstate and peroxytungstates were formed in the reaction.

Heat Capacity and Entropy

Low temperature heat capacities (52-299.87 K) were measured calorimetrically by King and Weller (6). The heat capacities above 300 K are estimated by extrapolation of the low temperature heat capacity curve to $C_p°(860\ K) = 49.0\ cal\ K^{-1}\ mol^{-1}$. The latter is obtained from an estimate of $C_p°$ equal to 7 cal K^{-1} g-atom at the first transition temperature.

The entropy, $S°(298.15\ K) = 38.32 \pm 0.5\ cal\ K^{-1}\ mol^{-1}$, is calculated from low temperature heat capacity data of King and Weller (6), based on an extrapolation of $S°(51\ K) = 2.77 \pm 0.5\ cal\ K^{-1}\ mol^{-1}$.

Transition Data

Transition temperatures and heats were obtained from differential heating and cooling curves both at atmospheric and higher pressures by Goranson and Kracek (7). Existence of three phases is confirmed by the earlier birefringence studies of Boeke (8).

Riccardi and Sinistri (10) found only one transition at 864 K with $\Delta_{trs} H° = 8.23\ kcal\ mol^{-1}$ by differential thermal analysis. This heat is apparently the sum of the two adopted heats of transition.

Fusion Data

The adopted melting data were measured by the differential heating and cooling curve method by Goranson and Kracek (7). Riccardi and Sinistri (10) found the melting point at 971 K with $\Delta_{fus} H° = 7.52\ kcal\ mol^{-1}$ by differential thermal analysis.

PREVIOUS: CURRENT: June 1967

$S°(298.15\ K) = 164.055 \pm 4.2\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(B \rightarrow A\beta) = 951\ K$

$T_{trs}(A\beta \rightarrow A\alpha) = 980\ K$

$T_{fus} = 1147\ K$

$\Delta_f H°(0\ K) = -2455.46 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2470.07 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{trs}H° = 0.418\ kJ\ mol^{-1}$

$\Delta_{trs}H° = 0.628\ kJ\ mol^{-1}$

$\Delta_{fus}H° = 35.564\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpies of solution of NaCl(cr), Na_2SO_4(cr) SiO_2(quartz), $Na_2Si_2O_5$(cr), HCl(aq) and H_2SO_4(aq), in 20% hydrofluoric acid at 74.7°C were measured by Kracek (1). The author derived two values of $\Delta_{sln}H°$ of Na_2O(cr) from those of NaCl(cr), Na_2SO_4(cr), HCl(aq) and H_2SO_4(aq), presumably employing auxiliary data from (2). We recalculate $\Delta_{sln}H°$ of Na_2O(cr) in the calorimetric solution as -87.50 (chlorine scheme, originally -87.66) and -88.74 kcal mol^{-1} (sulfate scheme, originally -89.19), using recent $\Delta_f H°(298.15\ K)$ values (16, 17, 18) for NaCl(cr), HCl(aq), H_2SO_4(aq), Na_2SO_4(cr), and Na_2O(cr). The corresponding enthalpy changes, $\Delta_r H°(298.15\ K)$, for the reaction $Na_2O(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(cr)$ are derived as -54.65 and -55.89 kcal mol^{-1}. Adopting the weighted average $\Delta_r H°(298.15\ K) = -55.06$ kcal mol^{-1} with $\Delta_f H°(Na_2O,\ cr,\ 298.15\ K) = -99.9$ kcal mol^{-1} and $\Delta_f H°(SiO_2,\ quartz,\ 298.15\ K) = -217.7$ kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K) = -590.36$ kcal mol^{-1} for $Na_2Si_2O_5$(cr). This $\Delta_f H°(Na_2Si_2O_5,\ cr,\ 298.15\ K)$ value is independent of future changes in $\Delta_f H°(298.15\ K)$ of Na_2O(cr), but the values of $\Delta_{sln}H°$ and $\Delta_r H°$ are not independent.

Stevens et al. (3) measured the enthalpies of solution of $Na_2Si_2O_5$(cr), Na_2O(cr) and SiO_2(quartz) in HF(aq) at 25°C. Based on the reported results, the enthalpy change for the reaction $Na_2O(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(cr)$ is calculated as -53.25 ± 0.32 kcal mol^{-1}, yielding $\Delta_f H°(Na_2Si_2O_5,\ cr,\ 298.15\ K) = -588.55$ kcal mol^{-1}.

Hummel (4) determined the enthalpies of solution of $Na_2Si_2O_5$(cr), SiO_2(quartz) and Na_2CO_3(cr) in 39% HF at 26.5°C. From the data reported we derive the enthalpy change to be 20.88 kcal mol^{-1} for the reaction $Na_2CO_3(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(cr) + CO_2(g)$. Employing $\Delta_f H°(298.15\ K) = -270.26$, -217.7 and -94.05 kcal mol^{-1} for Na_2CO_3(cr), SiO_2(quartz) and CO_2(g), respectively, we obtain $\Delta_f H°(298.15\ K) = -590.78$ kcal mol^{-1} for $Na_2Si_2O_5$(cr) which is in good agreement with the adopted one.

Heat Capacity and Entropy

The low temperature heat capacities, 54.3 - 294.7 K, have been measured by Kelley (5) and the high temperature enthalpies, 376.8 - 1100.2 K, by Naylor (6). The derived high temperature heat capacities are joined smoothly with the low temperature ones at 298.15 K. An approximate $C_p°$ of 70 cal K^{-1} mol^{-1} is derived from the enthalpies above 980 K; this value is extrapolated to 2000 K. The value of $S°(298.15\ K)$ is calculated from the adopted low temperature heat capacities based on $S°(50\ K) = 2.945$ cal K^{-1} mol^{-1}. The entropy extrapolation derives from the Debye-Einstein extrapolation of Kelley (5) which yields a $C_p°$ curve with an extra inflection in the region from 15 to 50 K. A more normal extrapolation would lead to a value of $S°(50\ K)$ which is lower by 0.5 cal K^{-1} mol^{-1}.

Transition Data

There are six slowly inverting polymorphous phases (1, 7-9), namely A, B, C, D, E and F, of which only the first two phases are stable. Two rapid transitions have been reported at 951 and 980 K (1, 10). Phase A, which has two subphases, Aα and Aβ, is stable above 951 K. The stable phase below 951 K is known as phase B, previously called β-$Na_2Si_2O_5$. The $\Delta_{trs}H°$ values are derived from the enthalpy data of Naylor (6) using the adopted $C_p°$ values. Three more rapid transitions have been reported at 822, 846 and 866 K (1, 10) in E, previously called γ-$Na_2Si_2O_5$. Willgallis and Range (10) have examined these transitions.

Fusion Data

T_{fus} is obtained from Morey (11). The selected value of $\Delta_{fus}H°$ is based on the following $\Delta_{fus}H°$ values derived from four different kinds of measurements.

Source	$\Delta_{fus}H°$, kcal mol^{-1} 298.15 K	1147 K	Method**
(12)	(7.51)	8.46	I
(1)	5.25	(6.20)	II
(13)	8.81	(9.76)	III
(14)	8.83	(9.78)	II
(15)	(7.50)	8.45	IV
(4)	8.09	(9.04)	II

* The numbers in parentheses are derived from the measured ones at the other listed temperatures.
**I = phase diagram, II = solution calorimetry; III = high temperature reaction calorimetry; and IV = dynamic-differential calorimetric method.

PREVIOUS: June 1965 CURRENT: September 1967

$S°(298.15\ K)$ = [188.705] J K^{-1} mol^{-1}

T_{fus} = 1147 K

$\Delta_f H°(298.15\ K)$ = [-2438.485] kJ mol^{-1}

$\Delta_{fus}H°$ = 35.564 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1147\ K)-H°(298.15\ K)$, between the crystal and liquid.

The enthalpies of solution of NaCl(cr), Na_2SO_4(cr), HCl(aq), H_2SO_4(aq), SiO_2(quartz) and $Na_2Si_2O_5(g, \ell)$ in 20% hydrofluoric acid at 74.7°C were measured by Kracek (1). Following the same procedure as described in the $Na_2Si_2O_5$(cr) table, we derive the enthalpy changes, $\Delta_r H°(298.15\ K)$, for the reaction $Na_2O(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(g, \ell)$ as -49.40 and -50.64 kcal mol^{-1} using the heats of solution of Na_2O(cr) as -87.50 (chloride scheme) and -88.74 kcal mol^{-1} (sulfate scheme), respectively. Adopting the weighted average $\Delta_r H°(298.15\ K)$ = -49.81 kcal mol^{-1} with $\Delta_f H°(Na_2O, cr, 298.15\ K)$ = -99.9 kcal mol^{-1} and $\Delta_f H°(SiO_2$, quartz, 298.15 K) = -217.7 kcal mol^{-1}, we obtain $\Delta_f H°(298.15\ K)$ = -585.113 kcal mol^{-1} for $Na_2Si_2O_5(g, \ell)$.

Using high temperature reaction calorimetry, Kroger (2) determined the enthalpy changes as 25.28 ± 0.22 and -18.58 ± 0.36 kcal mol^{-1} for the reactions $Na_2CO_3(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(g, \ell) + CO_2(g)$ and $2\ NaOH(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(g, \ell) + H_2O(\ell)$, *respectively. From the given results, we calculate the corresponding values of* $\Delta_f H°(Na_2Si_2O_5, g, \ell, 298.15\ K)$ to be -586.32 and -589.46 kcal mol^{-1}, using $\Delta_f H°(298.15\ K)$ = -270.26, -217.70, -94.05, -101.90 and -68.32 kcal mol^{-1} for Na_2CO_3(cr), SiO_2(quartz, CO_2(g), NaOH(cr) and $H_2O(\ell)$, respectively. These two $\Delta_f H°(Na_2Si_2O_5, \ell, 298.15\ K)$ values, as well as the value -585.113 kcal mol^{-1} based on Kracek's data, are not adopted, because incorporating these $\Delta_f H°(g, \ell, 298.15\ K)$ values with the value of $\Delta_f H°(cr, 298.15\ K)$, gives values of the enthalpy of melting at 298.15 K which are too low in comparison with the other values (see the $Na_2Si_2O_5$, cr, table).

Hummel (3) measured the enthalpies of solution of Na_2CO_3(cr), SiO_2(quartz) and $Na_2Si_2O_5(g, \ell)$ in 39% hydrofluoric acid at 26.5°C, as -244.1, -564.5 and -673.7 cal g^{-1}, respectively. Based on these results, we derive the enthalpy change for the reaction $Na_2CO_3(cr) + 2\ SiO_2(quartz) = Na_2Si_2O_5(g, \ell) + CO_2(g)$ to be 29.01 kcal mol^{-1}, yielding $\Delta_f H°(Na_2Si_2O_5, g, \ell, 298.15\ K)$ = -582.6 kcal mol^{-1} which is in good agreement with the adopted value.

Heat Capacity and Entropy

Using drop calorimetry, Naylor (4) has measured the enthalpies of $Na_2Si_2O_5(g, \ell)$, 445.5 - 1120.7 K, and $Na_2Si_2O_5(\ell)$, 1173.2 - 1744 K. Based on the liquid enthalpy data, we evaluate the heat capacity of $Na_2Si_2O_5(\ell)$ to be 62.43 cal K^{-1} mol^{-1}. The $C_p°$ values below 1147 K are derived from the enthalpies measured at 445.5 - 1120.7 K by Naylor (4). Below 600 K, $C_p°$ is identical with that of the crystal. The adopted curve rises rapidly to a maximum in the glass transition region, 650-950 K, then smoothly approaches the value of the real liquid near T_{fus}. The heat capacity of $Na_2Si_2O_5(\ell)$ is assumed to be constant in the temperature range 1147 to 2500 K.

$S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Sodium Silicate ($Na_2Si_2O_5$) $Na_2O_5Si_2$(cr,l)

$S°(298.15\ K) = 96.232 \pm 16.7\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = [1276 \pm 20\ K]$ (lambda transition)

$T_{fus} = 1445 \pm 10\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -366.10 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 0$

$\Delta_{fus} H° = [19.246 \pm 4.2]\ kJ\ mol^{-1}$

Enthalpy of Formation

We adopt the average value, $\Delta_f H°(298.15\ K) = -87.5\ kcal\ mol^{-1}$, derived from the experimental results summarized below.

Source	Reaction	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
(1)	$\Delta_{sln} H°$ $Na_2S(cr)$ and $Na(cr)$, $\Delta_n H°$ $NaOH(aq) + H_2S(aq)$	-88.2
(2)		-89.7
(3)	$Na\ (in\ NH_3) + S(cr) = Na_2S(cr)$	-87.0
(4)	$H_2SO_4(aq, 1100\ H_2O) + Na_2S(cr) = Na_2SO_4(soln.) + H_2S(g)$	-85.1*

* The author's value of -84.35 ± 0.9 kcal mol^{-1} is corrected for newer values for $\Delta_f H°(298.15\ K)$ of Na_2SO_4(c, V) and H_2S(g) (5, 11).

The adopted value is reasonably consistent with -86.6 ± 1 kcal mol^{-1} calculated from the 2nd law analysis of Uusitalo's equilibrium data (10) described in the following section.

Heat Capacity and Entropy

The heat capacity is based on the drop calorimetry of May (6) (400-1500 K). The pre-melt S-shaped enthalpy curve is reinterpreted as incorporating a lambda transition in view of the enthalpy measurements on K_2S by Dworkin and Bredig (7) and the occurrence of lambda transitions in other materials having the fluorite or anti-flourite type of structure (8). The adopted heat capacity shows the maximum of the lambda transition at 50.65 cal K^{-1} mol^{-1} and 1276 K. The heat capacity then falls to a constant value of 32 cal K^{-1} mol^{-1} at 1420 K. This interpretation along with the adopted melting point, heat of melting, and liquid heat capacity (22 cal K^{-1} mol^{-1}, 9) leads to an enthalpy of the liquid consistent with May's measurement.

May (6, 648-656 K) and Uusitalo (10, 462-763 K) have measured equilibrium pressures for the reaction $Na_2SO_4(cr) + 2\ C(solid) = Na_2S(cr) + 2\ CO_2(g)$ and have derived $S°(Na_2S, cr, 298.15\ K) = 18.6$ and 18.5 cal K^{-1} mol^{-1}. These derivations are open to question because of the uncertainty of the crystalline form of Na_2SO_4 used in the reaction (forward direction) or resulting from the reaction (reverse direction). Five crystalline forms of Na_2SO_4 have been identified (11, 12). $S°(298.15\ K)$ for form V, stable at room temperature, has erroneously been used to derive $S°(Na_2S, cr, 298.15\ K)$ rather than $S°(298.15\ K)$ for form I which is the form stable at the equilibrium measurement temperature. Furthermore, Uusitalo (10) used charcoal which probably deviates from graphite, the standard reference state. Our 2nd law treatment of Uusitalo's data (10) with auxiliary data for Na_2SO_4(cr, I) and C(graphite) (11), which is still questionable, leads to $S°(Na_2S, cr, 298.15\ K) = 23.2$ cal K^{-1} mol^{-1}. The agreement of this derivation with the estimate below is almost surely fortuitous.

Kubaschewski et al. (13) have estimated the entropy as 23.5 ± 2.5 cal K^{-1} mol^{-1}. Voronin's (14) estimate is 21.6 cal K^{-1} mol^{-1}. The summation of Kelley's additive entropy constants (15) gives 23.0 cal K^{-1} mol^{-1}. We adopt $S°(Na_2S, cr, 298.15\ K) = 23.0 \pm 4$ cal K^{-1} mol^{-1}.

Fusion Data

Tegman (16) indicated that many of the early measurements of the melting point of Na_2S were made on impure brown material. Several measurements on white or light pink material are in reasonable agreement: in °C, ~1200 (17), 1180 ± 10 (18), 1180 (19), 1160 ± 5 (20, 21), 1175 ± 10 (22), and 1168 ± 10 (23). We adopt a melting point of 1445 ± 10 K (1172 ± 10°C). This is consistent with May's (6) enthalpy measurements.

In an examination of May's enthalpy data, Wagman (24) has used an entropy of fusion of 3.21 cal K^{-1} mol^{-1} --the entropy of fusion of K_2S is 3.16 cal K^{-1} mol^{-1} --which leads to an entahlpy of fusion of 4.8 kcal mol^{-1} at the adopted melting point of 1445 K. From the Na_2S-S phase diagram work of Rosen and Tegman (23), Wagman (24) calculates an average enthalpy of fusion of 5.7 kcal mol^{-1} and recommends $\Delta_{fus} H° = 5 \pm 1$ kcal mol^{-1}. We adopt $\Delta_{fus} H° = 4.8$ kcal mol^{-1} to remain consistent with our incorporation of a lambda transition in the evaluation of May's (6) enthalpy measurements.

$S°(298.15\ K)$ = [127.656] J K^{-1} mol^{-1}

T_{fus} = 1445 ± 10 K

$\Delta_f H°(298.15\ K)$ = [-323.940] kJ mol^{-1}

$\Delta_{fus} H°$ = [19.246 ± 4.2] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Na_2S, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Na_2S, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1445\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of 22 cal K^{-1} mol^{-1} is from the estimated of Barin et al. (1) and is assumed to be constant above the assumed glass transition at 970 K. Below the glass transition, the heat capacity is that of the crystal.

The entropy at 298.15 K is calculated in a manner similar to that used for the enthalpy of formation.

PREVIOUS: CURRENT: March 1978

$S°(298.15\ K) = 150.6 \pm 24\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 423 - 523\ K$
$T_{fus} = 753 \pm 5\ K$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -397.1 \pm 8\ kJ\ mol^{-1}$
$\Delta_{trs} H°$ = Unknown
$\Delta_{fus} H° = [18.91 \pm 1.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

Kraus and Ridderhof (1) determined $\Delta_f H°(Na_2S_2, cr, 298.15\ K) = -96.2$ kcal mol^{-1} from the enthalpy of reaction of Na(in NH_3) and S(cr) to form Na_2S_2(cr) in liquid ammonia. Letoffe et al. (2) derived $\Delta_f H°(Na_2S_2, cr, 298.15\ K) = -92.7$ kcal mol^{-1} from the enthalpy of reaction of Na_2S_2(cr) and H_2SO_4(1100 H_2O) to form Na_2SO_4(acid solution), H_2S(g), and S(cr). With newer values for the enthalpies of formation of H_2SO_4(1100 H_2O) (3), Na_2SO_4(cr) (4), and H_2S(g) (4), the value of Letoffe et al. corrects to -93.6 kcal mol^{-1}. We adopt the average of $\Delta_f H°(Na_2S_2, cr, 298.15\ K) = -94.9 \pm 2$ kcal mol^{-1}.

Heat Capacity and Entropy

The heat capacities are those estimated by Barin et al. (5).

Mills (6) gives $S°(298.15\ K) = 21.4 \pm 5$ cal $K^{-1}\ mol^{-1}$ derived from the dissociation pressure measurements of Teder and Tiberg (7); the path of the derivation is not clear. Tegman (8) has measured the vapor pressure of sulfur over sodium polysulfide melts which he has supplemented with other measurements from the literature to form an extensive data set covering a composition range of $Na_2S_{1.3}$ - $Na_2S_{6.0}$ and a temperature range of 523 - 1273 K. His analysis of this data set via computer modeling gave, among other things, the entropy changes for the reactions: $Na_2S(\ell) + 1/2\ S_2(g) = Na_2S_2(\ell)$; $\Delta S° = -9.00$ cal $K^{-1}\ mol^{-1}$ and $Na_2S_2(cr) = Na_2S_2(\ell)$; $\Delta S° = 4.43$ cal $K^{-1}\ mol^{-1}$. It had been assumed these values are independent of temperature, but for our calculation of $S°(Na_2S_2, cr, 298.15\ K)$ we have used a temperature of 900 K, near the mid-point of the experimental range. With auxiliary data for $Na_2S(\ell)$ and $S_2(g)$ (4) and $S°(900\ K) - S°(298.15\ K)$ for Na_2S_2(cr) from a preliminary table, we derive $S°(Na_2S_2, cr, 298.15\ K) = 42.1$ cal $K^{-1}\ mol^{-1}$.

A graphical comparison of the standard entropies of K_2S(cr) (5), K_2S_3(cr) (19), K_2S_5(cr) (19), and Na_2S(cr) (5) indicates that 21.4 cal $K^{-1}\ mol^{-1}$ is probably too low and 42.1 cal $K^{-1}\ mol^{-1}$ is probably too high for $S°(Na_2S_2, cr, 298.15\ K)$. We adopt $S°(Na_2S_2, cr, 298.15\ K) = 36 \pm 6$ cal $K^{-1}\ mol^{-1}$.

Transition and Fusion Data

The existence of two forms of Na_2S_2 is well established (9-13), but the α-β transition is sluggish. Some indicate the transition is irreversible (9-12) while others find it reversible (13). On heating the α-form, it changes to the β-form in the 150-250° range (9, 12, 13) (423-523 K).

The melting point of the β-form has been determined as 473.9 (14), ~490 (9), 482±2 (15), 478±5 (16), 475 (17), 475 (12), 455 (13), and 484°C (18). We adopt 480±5°C (753±5 K).

The adopted $\Delta_{fus} H° = 4.52$ kcal mol^{-1} is taken from the tabulation of Barin et al. (5), referenced to private communications from Mills (6). It is not known if this is a measured or an estimated value. Tegman (8) derived a $\Delta_{fus} H° = 4.62$ kcal mol^{-1} from liquid-vapor and solid-liquid equilibria data via complex computer modeling. This indirectly calculated figure apparently corresponds to an average temperature of approximately 1000 K so that $\Delta_{fus} H°(753\ K) \sim 4.8$ kcal mol^{-1}; this value tends to confirm the adopted value and is used in estimating an uncertainty of ±0.4 kcal mol^{-1}.

$S°(298.15\ K) = [172.365]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 753 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-380.114]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [18.91 \pm 1.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Na_2S_2, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(753 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of 29.8 cal K^{-1} mol^{-1} is from the estimate of Barin et al. (1) and is assumed to be constant above an assumed glass transition at 500 K. Below the glass transition, the heat capacity is that of the crystal.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the β-crystal table for details.

$S°(298.15\ K) = 36.46 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2750 \pm 10\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 26.90 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity values for T < 10 are chosen to be the same as those adopted by Hultgren et al. (1). A graphical integration of these Cp° data yields S°(10 K) = 0.029 J K^{-1} mol^{-1} and H°(10 K) = 0.19 cal mol^{-1}. The work by DaSilva et al. (2, 3) on the low temperature (1-10 K) heat capacity of annealed and unannealed niobium wires in magnetic fields supports this choice. Clusius et al. (4) measured the heat capacity (61 pts.) in the region 11-274 K. This data is smoothed graphically and is constrained to join smoothly with the Cp° values for T ≤ 10 K. Deviations up to 4% occur between the observed and adopted Cp° values for T < 80 K. The deviations here parallel the deviations obtained in our analysis of the heat capacity for Ta (5). The deviations decrease steadily with increasing temperature up to 274 K.

There are numerous high temperature heat capacity and enthalpy measurements for Nb(cr). The various studies are listed below.

Source	T/K	Method
(6)	273-1873	drop
(7)	454-1882	drop
(8)	433-1840	drop
(9)	1400-2350	modul
(10)	1300-2700	modul
(11)	358-1415	drop
(12)	600-2600	drop
(13)	1273-2593	drop
(14)	1100-2400	pulse
(15)	1500-2700	pulse
(16)	1650-2707	drop

The adopted Cp° values for T > 298.15 K are obtained by a combination of graphical and polynomial curve fitting techniques. A polynomial curve fit procedure is used on the enthalpy data of Hawkins and Orr (11) with the constraint that it join smoothly in the 298.15 K region with the enthalpy derived from the Clusius et al. (4) heat capacity data. Above 1300 K, a heat capacity curve is adopted through graphical procedures. The adopted curve is chosen so as to be intermediate between the Cp° values of Cezairliyan (15) and the higher Cp° values implied from the enthalpy data of Kirillin et al. (12) and Sheindlin et al. (16). In general there is good agreement between the various sets of data.

The heat capacity values near T_{fus} are the smoothed values suggested by Cezairliyan (15). In comparison with the adopted Cp° values, Cezairliyan's smoothed data lies low by 1.9% at 1500 K with the difference steadily decreasing to zero at 2600 K. The smoothed results of Cezairliyan (15) are used for extrapolation to 3200 K. The Cp° values reported by Makarenko and Trukhanov (14) are linear in the region 1100-2400 K whereas the adopted Cp° values are nonlinear; the Cp° - T curve being concave upward in this region. The Cp° values of Makarenko and Trukhanov (14) are within -0.4% to +0.8% of the adopted values in the region 1400-2100 K but drift to -3% at 1100 K and 2400 K. In comparing enthalpies, Kirillin et al. (12) reported smoothed values (12) which are 15 cal mol^{-1} or 0.8% lower than our tabulated values at 600 K and drift to 849 cal mol^{-1} or 4.5% higher at 2700 K. The enthalpy results of Sheindlin et al. (16) lie above the JANAF values by 0.9% in the region 1700-2700 K (82 cal mol^{-1} at 1700 K and 181 cal mol^{-1} at 2700 K).

Fusion Data

See the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K)$ for Nb(cr) = Nb(g) is simply $\Delta_f H°(298.15\ K)$ for Nb(g). See the ideal gas table for details.

PREVIOUS: June 1972 CURRENT: December 1973

$S°(298.15\ K) = [47.302]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2750 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [29.647]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 26.90 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Nb(ℓ) at 298.15 K is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2750 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The enthalpy measurements on Nb(ℓ) by Sheindlin et al. (7) and Margrave (8) do not extend over a sufficiently wide temperature range such that a heat capacity value could be derived. Therefore, the heat capacity for Nb(ℓ) is estimated as 8.0 cal K^{-1} mol^{-1} by analogy with other monatomic metals. The entropy at 298.15 K is calculated in a manner analogous to that used in calculating the enthalpy of formation. A glass transition is assumed at 1750 K. The heat capacity values used below 1750 K are those of Nb(cr).

Fusion Data

Melting point determinations for Nb have been numerous, with most reported values in the range 2680-2795 K (IPTS-68 scale). A prime cause for diversity in the results is that the melting point is quite sensitive to impurities, especially gases such as oxygen and nitrogen. These effects have been documented by Schofield (1) and Pemsler (2). The value chosen is 2750 ± 10 K as reported by Cezairliyan (3) using a subsecond pulse heating method. This value is consistent with the heat capacity values near T_{fus} which are also based on related work by Cezairliyan (4). Other values in this range (corrected to IPTS-68 scale) are 2746 K by Schofield (1), 2745 K by Pemsler (2), and 2738 K by Buehler (5). Kocherzhinskii and Kobzenko (6) have reported a T_{fus} value of 2793 K, using a sample purified by electron zone fusion.

The value chosen for $\Delta_{fus}H°$ is 6.43 ± 0.20 kcal mol^{-1} as determined by Cezairliyan (3) using a pulse heating technique. Adopting this value gives consistency between the Cp° values near T_{fus}, $\Delta_{fus}H°$, and T_{fus} as all these values are dependent upon the same heating technique. Sheindlin et al. (7) reported $\Delta_{fus}H°$ = 6.597 ± 0.170 kcal mol^{-1} based on enthalpy measurements on Nb(cr) and Nb(ℓ) obtained from levitation calorimetry techniques. In the vicinity of T_{fus}, the adopted enthalpy vlaues for Nb(cr) and Nb(ℓ) lie roughly 200 cal mol^{-1} lower than those reported by Sheindlin et al. (7). Margrave (8), also using levitation techniques, reported a value $\Delta_{fus}H°$ = 7.9 kcal mol^{-1}. It is felt that Margrave's value was calculated from a measured enthalpy of Nb(ℓ) at T_{fus} and the enthalpy of Nb(cr) at T_{fus} as suggested by Hultgren et al. (9). Our enthalpy vlaues at T_{fus} for Nb(cr) would reduce Margrave's value to roughly 7.4 kcal mol^{-1} for $\Delta_{fus}H°$.

Martynyuk and Tsapkov (10) measured the enthalpies of Nb(cr) and Nb(ℓ) at the melting point using the method of pulse heating. They reported enthalpy of melting value of 7.98 kcal mol^{-1} for an Nb sample which was reported to be 99.94% pure. No T_{fus} value was reported.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change for the reaction Nb(ℓ) = Nb(g) is zero. The difference between $\Delta_f H°$(Nb, g) and $\Delta_f H°$(Nb, ℓ) at T_{vap} is $\Delta_{vap}H°$. The uncertainty in the boiling point is probably of the order of ±100 K. Also refer to Nb(g) table.

Enthalpy of Formation

A 2nd and 3rd law analysis of six reported vapor pressure studies is tabulated below. Five studies (1-5) used the Langmuir free evaporation method while one study (6) used the integral variation of the Knudsen method.

Source	Reaction	T/K (IPTS-68)	Data points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

(6)	B	2553-2684	4	143.1	191.4	18.4±4.8	191.4

* 2939.9 K point deleted due to a statistical test. A = vaporization

** 2307, 2328, 2584 K points deleted due to a statistical test. B = sublimation

We adopt $\Delta_f H°(298.15\ K) = 175.2$ kcal mol^{-1} for Nb(g) which is a rounded average of four results (2, 3, 4, 5). With a drift of 7.5 cal K^{-1} mol^{-1} in that data, Shchukarev et al. (7) reported an enthalpy of sublimation of Nb(cr), determined at 2243-2393 K, of 172 ± 5 kcal mol^{-1}. Our tabulations give $\Delta_{sub}H°(2300\ K) = 173.5$ kcal mol^{-1}. *The same workers (7) later reported* $\Delta_{sub}H°(298.15\ K) = 173$ kcal mol^{-1} based on a 2nd law analysis of Nb^+ ion currents at temperatures above 2573 K.

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from Moore (8). Only a few of the levels are listed above. All levels reported by Moore (4) are considered in the calculation. There are predicted electronic levels which have not been observed (8). These levels are assumed to lie above 20,000 cm^{-1} and thus will not significantly affect the entropy at temperatures below 3000 K. The heat capacity and entropy values are very similar to those adopted by Hultgren (9), being the same at 298.15 K and differing by 0.39 cal K^{-1} mol^{-1} in Cp at 5500 K.

NIOBIUM, ION (Nb^+) IDEAL GAS M_r = 92.90585

$IP(Nb^+, g) = 115500 \pm 100\ cm^{-1}$

$S°(298.15\ K) = 183.333 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1394.0 \pm 8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [1402.954]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i cm^{-1}	g_i
$^5D_0$	0.00	1
$^5D_1$	158.38	3
$^5D_2$	438.99	5
$^5D_3$	801.38	7
$^5D_4$	1224.87	9

Enthalpy of Formation

$\Delta_f H°(Nb^+, g, 0\ K)$ is calculated from $\Delta_f H°(Nb, g, 0\ K)$ (1) using the spectroscopic value of IP(Nb) = 55511 ± 1 cm^{-1} (55511 ± 1 cm^{-1} (664.059 ± 0.01 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Nb^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Nb, g, 0\ K)$ by using IP(Nb) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Nb(g), $Nb^+(g)$, and $e^-(g)$. $\Delta_f H°(Nb \rightarrow Nb^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first excited state, the highest observed excited state, and the ionization potential for $Nb^+(g)$, all levels listed by Moore (6), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $Nb^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=4, 5), the cut-off procedure, and the inclusion of n=5 levels up to 6000 K; the Gibbs energy function showing variations of 0.2 % at this temperature. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>5), and use of different fill and cut-off procedures (7).

PREVIOUS: CURRENT: March 1984 (1 bar)

Niobium, Ion (Nb^+) $Nb_1^+(g)$

EA(Nb, g) = 0.893 ± 0.025 eV

$S°(298.15\ K)$ = 186.095 ± 0.002 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 643.763 ± 4.5 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [640.978] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^5D_0$	0.0	1
$^5D_1$	110	3
$^5D_2$	310	5
$^5D_3$	560	7
$^5D_4$	870	9

Enthalpy of Formation

$\Delta_f H°(Nb^-, g, 0\ K)$ is calculated from $\Delta_f H°(Nb, g, 0\ K)$ (1) using the adopted electron affinity of EA(Nb) = 0.893 ± 0.025 eV (86.161 ± 2.412 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Nb^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Nb^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Nb, g, 0\ K)$ by using EA(Nb) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Nb^-(g)$, Nb(g), and $e^-(g)$. $\Delta_r H°(Nb^- \rightarrow Nb + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Nb^-(g)$ is given by Hotop and Lineberger (2, 4), Rosenstock et al (5), and Massey(6). The fine structure separation has been calculated by an isoelectronic extrapolation of ratios of fine structure separations (3) and is that recommended by Hotop and Lineberger (2).

PREVIOUS: CURRENT: March 1984 (1 bar)

$S°(298.15\ K) = [46.024 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2210 \pm 15\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -419.66 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 85.354 \pm 20.9\ kJ\ mol^{-1}$

$\Delta_{sub} H°(298.15\ K) = 618.395 \pm 20.9\ kJ\ mol^{-1}$

Enthalpy of Formation

There are two reported oxygen bomb calorimetric studies for NbO(cr). The results must be interpreted in light of impure samples, incomplete combustion to Nb_2O_5(cr), and the possible nonstoichiometry of the reactants and products. Morozova and Getskina (1) reported $\Delta_c H°(291\ K) = 255.0$ kcal mol^{-1} while Kusenko and Gel'd (2) reported $\Delta_c H°(298.15\ K) = 263.2$ kcal mol^{-1} for the combustion of NbO(cr). Using auxiliary data (3), we calculate $\Delta_f H°(298.15\ K) = -99.5$ and -95.4 kcal mol^{-1} for NbO(cr). Schaefer and Liedmeier (4), using Cl_2 bomb calorimetry, reported a value of -97 ± 1 kcal mol^{-1}, based on $\Delta_f H°(NbOCl_3, cr, 298.15\ K) = -210.2$ kcal mol^{-1}.

A 2nd and 3rd law analysis of the majority of the reported smoothed emf data is tabulated below. Note that the enthalpy of formation for NbO(cr) calculated from the 3rd law $\Delta_r H°$ values are roughly 3 kcal mol^{-1} more negative than the adopted value. There is, however, excellent agreement within the equilibrium data; the 3rd law $\Delta_f H°(298.15\ K)$ values average -100.3 kcal mol^{-1} with a spread of only 1.8 kcal mol^{-1}. We adopt $\Delta_f H°(298.15\ K) = 100.3 \pm 3.0$ kcal mol^{-1} based on an average of the equilibrium studies (5-11). The reason for the discrepancy between the equilbrium and combustion results is not known at this time (8).

A) $Nb(cr) + Fe_{0.95}O = NbO(cr) + 0.95\ Fe(cr)$

B) $Nb(cr) + 0.2\ Ta_2O_5(cr) = 0.4\ Ta(cr) + NbO(cr)$

C) $Nb(cr) + 1/3\ Cr_2O_3(cr) = NbO(cr) + 2/3\ Cr(cr)$

Heat Capacity and Entropy

Gel'd and Kusenko (12) measured the enthalpy of NbO(cr) and reported fourteen data points in the range 420-1702 K (IPTS-68). A Shomate-type equation is used to represent the data. The average deviation between the data and calculated values is 0.31%; the maximum deviation of 0.62% occurs at 1518 K. This equation is used to obtain extrapolated values of $C°_p$ up to T_{fus}.

There is no low temperature heat capacity data reported in the literature for T < 298 K. In order to have the 3rd law results of the equilibrium data agree with the combustion data, an entropy value of the order of 13-14 cal K^{-1} mol^{-1} would be necessary. At this point, however, the 3rd law drifts would be all positive. S°(298.15 K) = 10.2 cal K^{-1} mol^{-1} would lead to a more satisfying variation in the 3rd law drifts for the condensed phase equilibrium data but an intermediate value S°(298.15 K) = 11.0 cal K^{-1} mol^{-1} gives better consistency with the vapor pressure data. For more details refer to the NbO(g) and NbO_2(g) tables (3).

Phase Data

Brauer (13) reported a homogeneity range of x = 0.89-1.04 for NbO_x. NbO(cr) has a cubic structure, a NaCl type with ordered vacancies (13, 14). Further information may be found in the review of the Nb-O system by Elliott (15).

Fusion Data

See the liquid table for details.

Sublimation Data

The mass spectrometric study by Shchukarev et al. (16) indicated that NbO(cr) at elevated temperatures yields NbO(g) and NbO_2(g). In the range 1873-2473 K, the concentration of NbO in the vapor phase over NbO(cr, ℓ) varied in the range 5-30% (16). $\Delta_{sub} H°(298.15\ K) = 147.8 \pm 5.0$ kcal mol^{-1} is calculated as the difference between the $\Delta_f H°(298.15\ K)$ values for NbO(g) and NbO(cr).

PREVIOUS: CURRENT: December 1973

$S°(298.15\ K) = 83.233\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2210 \pm 15\ K$

$\Delta_f H°(298.15\ K) = -336.743\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 85.354 \pm 20.9\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(NbO, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(NbO, cr, 298.15K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(2210\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

There is no data reported in the literature concerning the heat capacity or enthalpy of $NbO(\ell)$. We estimate a constant value of $C_p° = 13.0\ cal\ K^{-1}\ mol^{-1}$ for the liquid phase. A glass transition is also assumed at 1500 K, so as to insure the proper thermodynamic relationship between the crystal values and extrapolated liquid values. At temperatures below 1500 K, $C_p°$ values of the crystal are used. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Elliott (1) reported the melting point of NbO(cr) as T_{fus} = 2222 K (IPTS-68). Measurements by Kolchin and Sumarokova (2) gave T_{fus} = 2212 K (IPTS-68). The vapor pressure study of NbO(cr, ℓ) by Shchukarev et al. (3) gave T_{fus} = 2207 K. We adopt T_{fus} = 2210 ± 15 K in order to maintain good consistency with the vapor pressure data.

Since the crystal structure of NbO(cr) is a defect NaCl structure, we can estimate $\Delta_{fus} H°$ = 13.9 kcal mol^{-1} based on $\Delta_{fus} S°$ = 6.27 cal $K^{-1} mol^{-1}$ as observed for NaCl (4). The data of Shchukarev et al. (3) are more consistent with $\Delta_{fus} H°$ = 20.4 kcal mol^{-1}, as determined from our analysis of the vapor pressures over NbO(cr, ℓ) (4). We adopt $\Delta_{fus} H°$ = 20.4 ± 5.0 kcal mol^{-1}. This leads to $\Delta_{fus} S°$ = 9.23 cal $K^{-1}\ mol^{-1}$ which is roughly 3 cal $K^{-1}\ mol^{-1}$ greater than the NaCl value (4).

Vaporization Data

The vapors over NbO(ℓ) have been shown by Shchukarev et al. (3) to be NbO(g) and NbO_2(g). At 2300 K, the rates of the vapor pressures NbO_2(g):NbO(g) is 1.00:0.23 (3).

$S°(298.15\ K) = 238.976 \pm 3.56\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 199.54 \pm 20.9\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 198.74 \pm 20.9\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$X[^4\Sigma^-]$	0	4
$[^4\Pi]$	15000	8
$[^4\Sigma^-]$	21316.2	4

$\omega_e = 989.03\ cm^{-1}$ $\omega_e x_e = 3.83\ cm^{-1}$ $\sigma = 1$

$B_e = 0.432\ cm^{-1}$ $\alpha_e = 2.1 \times 10^{-3}\ cm^{-1}$ $r_e = 1.691$ Å

Enthalpy of Formation

Using the adopted vibrational constants [ω_e and $\omega_e x_e$], we calculate D° = 7.855 eV as the dissociation energy of NbO(g) based on the linear Birge-Sponer extrapolation of the ground state. Applying a correction for the ionicity in the Nb-O bond as suggested by Hildenbrand and Murad (1), we recalculate D° = 8.032 eV. This latter value corresponds to $\Delta_f H°$(NbO, g, 298.15 K) = 48.03 kcal mol^{-1}, assuming dissociation to normal atoms, while the former yields 52.11 kcal mol^{-1}.

Shchukarev et al. (2, 3) have investigated mass spectrometrically the composition of the vapors over NbO(cr, ℓ) and NbO_2(cr, ℓ). In their first work (2), the authors reported that, besides NbO sublimation at 1773-1923 K, the reaction 2 NbO(cr) = Nb(cr) + NbO_2(g) occurs. A 2nd law $\Delta_{sub}H°$ = 138 ± 3 kcal mol^{-1} was reported for the range 1773-1923 K. Using auxiliary data (5), we calculate $\Delta_f H°$(NbO, g, 298.15 K) = 47.2 ± 3.0 kcal mol^{-1}, assuming the $\Delta_{sub}H°$ reported value refers to 1900 K.

Shchukarev et al. (3) measured the vapor pressures of NbO and NbO_2(cr, ℓ) and NbO_2(cr, ℓ) by the effusion method coupled with a mass spectrometer. The results are summarized in the following table.

Reaction	T/K	$\Delta_r H°$(298.15 K), kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°$(298.15 K), kcal mol^{-1} 2nd law	3rd law
NbO(cr) = NbO(g)	1773-2210	148.0	147.5	-0.24	47.7	47.2
NbO(ℓ) = NbO(g)	2210-2473	128.1	128.0	-0.04	47.6	47.5

We adopt $\Delta_f H°$(298.15 K) = 47.5 ± 5.0 kcal mol^{-1} for NbO(g). The adopted value is an average value based on the 2nd and 3rd law results tabulated above. It is interesting to note that the adjusted Birge-Sponer result shows excellent agreement with the adopted $\Delta_f H°$(298.15 K). The adopted $\Delta_f H°$(298.15 K) leads to a dissociation energy D° = 8.05 eV.

Heat Capacity and Entropy

The spectroscopic work involving NbO(g) has been reviewed and referenced by Rosen (4). The adopted vibrational and rotational constants as well as the electronic levels are those tabulated by Rosen (4). As indicated in Rosen (4), the data suggest a $^4\Sigma^-$ ground state as in VO(g) (5). However, a possible ground state $^2\Delta$ as in TaO(g) (5) is not definitely excluded. The recent reviews by Cheetham and Barrow (6) and Weltner (7) favor a $^2\Delta$ ground state. Using a $^2\Delta$ ground state and $^2\Delta$-$^2\Delta$ transition at 21316.2 cm^{-1} produces the same thermodynamic functions as does a $^4\Sigma^-$ ground state and a $^4\Sigma$-$^4\Sigma$ transition at 21316.2 cm^{-1}. Green et al. (9) studied the infrared absorption spectra of isotopic NbO isolated in an Ar matrix. Green et al. (9) reported that a partial analysis of the observed bands supported the assignment of a $^4\Sigma^-$ electronic ground state for NbO.

The free energy functions used here are approximately 0.85 cal K^{-1} mol^{-1} at 298 K and 2.90 cal K^{-1} mol^{-1} at 3000 K lower than those proposed by Brewer and Rosenblatt (8). The difference arises from the fact that Brewer and Rosenblatt (8) approximated the NbO electronic levels by using Nb^{++} electronic levels (which included low lying levels) whereas we have used the observed NbO electronic levels.

NIOBIUM OXIDE (NbO_2) CRYSTAL (I-II-III) M_r = 124.9052

$S°(298.15\ K) = 54.506 \pm 0.29\ J\ K^{-1}\ mol^{-1}$

$T_{trs1} = 1090 \pm 20\ K$

$T_{trs2} = 1200\ K$

$T_{fus} = 2175 \pm 15\ K$

$\Delta_f H°(0\ K) = -790.31 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -794.96 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_{trs1} H° = 3.423\ kJ\ mol^{-1}$

$\Delta_{trs2} H° = 0.000\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 92.048 \pm 20.9\ kJ\ mol^{-1}$

Enthalpy of Formation

There are three oxygen bomb calorimetric studies for NbO_2(cr). As with NbO(cr), the combustion results must be interpreted in light of impure samples, possible incomplete combustion, and possible nonstoichiometry. The following $\Delta_c H°$ results have been reported for the oxygen combustion of one mole of NbO_2(cr) to yield Nb_2O_5(cr): 37.0 ± 0.4 kcal mol^{-1} (291 K) by Morozova and Getskina (1), 37.6 ± 2.6 kcal mol^{-1} (298 K) by Kusenko and Gel'd (2), and 36.67 ± 0.10 kcal mol^{-1} (298 K) by Mah (3). Using the value $\Delta_c H°(298.15\ K) = 37.0 \pm 2.0$ kcal mol^{-1} and JANAF auxiliary data (4), we calculate and adopt $\Delta_f H°(NbO_2, cr, 298.15\ K) = -190.0 \pm 2.0$ kcal mol^{-1}.

There are numerous equilibrium studies involving NbO_2. Early work involved the reduction of niobium oxides with hydrogen by Grube et al. (5), Sue (6), and Schaefer and Breil (7), and the carbon reduction of Nb_2O_5 by Sue (8). The more recent emf equilbrium studies are analyzed and tabulated in the following table.

Source	T/K	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(9)	1673-1823	$NbO_2(cr)+H_2(g)=NbO(cr)+H_2O(g)$	36.35	32.30	-2.3	-190.4
(10)	1100-1300	$NbO_2(cr)+Nb(cr)=2\ NbO(cr)$	-11.96	-9.59	2.0	-187.8
(11)	1074-1175	$Nb_2O_5(cr)+C(cr)=2\ NbO_2(cr) + CO(g)$	38.43	45.87	6.6	-190.9
(12)	1177-1361	$NbO(cr)+1/3\ Cr_2O_3(cr)=NbO_2(cr)+2/3\ Cr(cr)$	2.32	1.78	-0.4	-188.9

Heat Capacity and Entropy

King (13, 53-296 K) measured the heat capacity of NbO_2(cr). Using the combination of Debye and Einstein functions suggested by King (13), we calculate $S°(51\ K) = 0.616$ cal $K^{-1}mol^{-1}$ and $H°(51\ K)-H°(0\ K) = 23$ cal K^{-1} mol^{-1}. The enthalpy data of Gel'd and Kusenko (14), and King and Christensen (15), indicated a transition in the region 1000-1200 K. We adopt the reported enthalpy equations of King and Christensen (15) for the ranges 1090-1200 K and 1200-1800 K. The latter equation is extrapolated to T_{fus}. For the region 298-1090 K, we use a five term polynomial to fit the enthalpy data of King and Christensen (15) with constraints to join smoothly with the enthalpy derived from the King data (13): the deviations are +0.34 to -0.67% in this range 298-1090 K. In the same range, the Gel'd and Kusenko data (14) lies approximately 2-3% higher; for T > 1200 K, it is 0.6-2.5% high.

Phase Data

Brauer (16) reported a homogeneity range of x = 1.95 to 2.05 for NbO_2. A recent study by Janninck and Whitmore (17), using isopiestic reduction techniques at 1373 K, reported x = 1.9975 to 2.003.

Brauer (16), Magneli et al. (18), Terao (19), and Marinder (20) have shown that at room temperature NbO_2 has a deformed rutile structure. NbO_2 is similar to V_2O_4 in terms of crystal structure (21).

Transition Data

Electric conductivity and thermoelectric power measurements and a DTA and x-ray diffraction study indicated a phase transition in the region 1068-1173 K (17, 21, 22). In this region, the structure of NbO_2 transforms from a deformed rutile to a rutile structure. The evidence suggested that the transition is not sharp but is actually spread over at least 50° (21).

The enthalpy data of King and Christensen (15) and Gel'd and Kusenko (14) are consistent with the above interpretation. We treat this transition as first order with $T_{trs1} = 1090 \pm 20$ K and add an artificial transition $T_{trs2} = 1200$ K as in King and Christensen (15). This combination reduces the reported enthalpy data (15). The value $\Delta_{trs1} H° = 0.818$ kcal mol^{-1} is calculated as the difference between the enthalpies of the two "phases" at 1090 K associated with the transition at T_{trs1}.

Fusion Data

See liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K) = 142.1 \pm 5.0$ kcal/mol is calculated as the $\Delta_f H°(298.15\ K)$ differences for NbO_2(g) and NbO_2(cr).

PREVIOUS: CURRENT: December 1973

$S°(298.15\ K) = [92.835]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2175 \pm 15\ K$

$\Delta_f H°(298.15\ K) = [-710.872]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 92.048 \pm 20.9\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(NbO_2, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(NbO_2, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(2175\ K)-H(298.15\ K)$, between the crystal and the liquid.

Heat Capacity and Entropy

There is no data reported in the literature concerning the heat capacity or enthalpy of $NbO_2(\ell)$. We estimate a constant value of $C_p° = 7.5\ cal\ K^{-1} g\text{-atom}^{-1}$ or $22.5\ cal\ K^{-1} mol^{-1}$ for the liquid phase. A glass transition is assumed at 1000 K below which the $C_p°$ values of the crystal are used. The entropy at 298.15 K is calculated in a manner analogous to that used in calculating the enthalpy of formation.

Fusion Data

Elliott (1) reported the melting point of $NbO_2(cr)$ as T_{fus} = 2191 K (IPTS-68) and stated that $NbO_2(cr)$ melts without decomposition. The vapor pressure study on $NbO_2(cr, \ell)$ by Shchukarev et al. (2) gave T_{fus} = 2173 K (IPTS-68) with congruent melting. We adopt $T_{fus} = 2175 \pm 15$ K in order to maintain good consistency with the vapor pressure data. A value of T_{fus} = 2357 K reported by Kolchin and Sumarokova (3) appears too high.

The vapor pressure data of Shchukarev et al. (2) suggests $\Delta_{fus} H° = 22.0\ kcal\ mol^{-1}$ which we adopt. This leads to $\Delta_{fus} S° = 10.11\ cal\ K^{-1}\ mol^{-1}$.

Vaporization Data

The vapors over $NbO_2(\ell)$ have been shown by Shchukarev et al. (2) to be NbO(g), $NbO_2(g)$, and O(g). At 2300 K, the ratio of the vapor pressures $NbO_2(g)$:NbO(g) is 1.00:0.07.

PREVIOUS: CURRENT: December 1973

Niobium Oxide (NbO_2) Nb_1O_2(cr,l)

$S°(298.15\ K) = [272.921 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -197.33 \pm 20.9\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -200.00 \pm 20.9\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[970](1)
[300](1)
[930](1)

Ground State Quantum Weight: [2] σ = [2]
Point Group: [C_{2v}]
Bond Distance: Nb-O = [1.691] Å
Bond Angle: O-Nb-O = [110]°
Product of the Moments of Inertia: $I_A I_B I_C = [5.274350 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

Shchukarev et al. (1-4) measured the vapor pressures of NbO and NbO_2 over NbO(cr, ℓ) and NbO_2(cr, ℓ) by the effusion method coupled with a mass spectrometer. An analysis of the reported smoothed results is presented in the following table (4).

Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law
NbO_2(cr) = NbO_2(g)	1773-2175	142.0	143.4	0.69	-48.0	-46.6
NbO_2(ℓ) = NbO_2(g)	2175-2473	124.2	123.7	-0.22	-46.8	-46.3
2 NbO(cr) = NbO_2(g) + Nb(cr)	1773-2210	147.8	149.9	1.03	-52.8	-50.7
2 NbO(ℓ) = NbO_2(g) + Nb(cr)	2210-2473	119.7	111.1	-3.73	-41.3	-49.9

We adopt $\Delta_f H°(NbO_2, g, 298.15\ K) = -47.8 \pm 5.0$ kcal mol^{-1}. This value is an average value of the 2nd and 3rd law results for the sublimation and vaporization of NbO_2. This adopted $\Delta_f H°(298.15\ K)$ value leads to D_0^0 = 14.73 eV for the process $NbO_2(g)$ = Nb(g) + 2 O(g). The D_0^0 value is 1.83 times as great as the dissociation energy of NbO(g) (8.05 eV, 2).

The earlier less complete studies by Shchukarev et al. (1-3) are in fair agreement with the above conclusions. Using a platinum strip to vaporize NbO_2(cr) in a mass spectrometer at temperatures of 1500 to 1880 K, Shchukarev et al. (1) reported a 2nd law sublimation heat, $\Delta_{sub}H°(1700\ K) = 142 \pm 3$ kcal mol^{-1}. Using auxiliary data (6), we calculate $\Delta_f H°(NbO_2, g, 298.15\ K)$ = -38.8 kcal mol^{-1}. The mass spectrometric investigation of the NbO(cr) evaporation by Shchukarev et al. (2) led to a reported value $\Delta_r H°(1800\ K) = 140 \pm 3$ kcal mol^{-1} for the process 2 NbO(cr) = Nb(cr) + NbO_2(g). Using auxiliary data (6), we calculate $\Delta_f H°(NbO_2, g, 298.15\ K)$ = -53.3 kcal mol^{-1}. NbO_2 pressures were obtained (1938-2122 K) by the differential effusion method using the radioactive tracer ^{95}Nb (3). The pressures agree within 5% of those obtained in the more complete study (4). Golubtsov et al. (5) also measured the vapor pressure of NbO_2(g) over NbO_2(cr) in the range 1489-1905 K by using labelled atoms in a Knudsen cell. The same authors also studied the dissociation of Nb_2O_5 in vacuo in the range 1432-1756 K, the process being Nb_2O_5(cr) + 2 NbO_2(g) + 1/2 O_2(g). These latter data (5) are not considered.

Heat Capacity and Entropy

The vibrational frequencies and geometry of NbO_2(g) are estimated based on existing and estimated data for related metal dioxides such as TiO_2(g), TaO_2(g), and WO_2(g) (6). The Nb-O bond distance is assumed to be the same as in NbO(g) (6). The ground state quantum weight of 2 is adopted so as to be consistent with TaO_2(g) (6). The principal moments of inertia are calculated as $I_A = 3.7181 \times 10^{-39}$, $I_B = 10.1954 \times 10^{-39}$, and $I_C = 13.9136 \times 10^{-39}$ g cm^2.

$S°(298.15\ K) = 137.30 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1785 \pm 30\ K$

$\Delta_f H°(0\ K) = -1889.616 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1899.536 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 104.265 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The $\Delta_f H°(Nb_2O_5$, cr, 298.15 K) investigations suffer from uncertainties concerning the polymorphic state of the samples employed and the oftentimes incomplete impurity analysis of the samples (1). There is considerable scatter in the following tabulation for the enthalpy of formation values, all of which are based on enthalpy of combustion studies.

Source	Nb(cr) purity, %	% completion*	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
(2)			-442.8
(3)	98.8	96.34 - 96.94	-459.9 ± 0.7**
(4)	99.69	97.63 - 99.38	-454.0 ± 0.6**
(5)			-472.6 ± 1.0
(6)	99.49		-454.8 ± 0.8
(7)			-458.6 ± 5.0
(8)	99.01	99.1 - 99.33	-455.1 ± 0.5
(9)	99.45	98.78 - 100	-454.4 ± 1.6
(10)	98.47 - 99.35	99.48 - 99.96	-453.5 ± 0.4
(11)	98.47 - 99.35	99.48 - 99.96	-453.5 ± 0.4
(12)			-456.9

* Percent completion refers to extent of reaction 2 Nb(cr) + 2.5 O_2(g) = Nb_2O_5(cr).

** Values adjusted by Kubaschewski and Catterall (13) to more satisfactorily correct for incomplete reaction.

The value chosen for $\Delta_f H°(Nb_2O_5$, cr, 298.15 K) is -454.0 ± 1 kcal mol^{-1}. This value is representative of the work by Humphrey (4), Kornilov et al. (10, 11), Huber et al. (9), Kusenko and Gel'd (8) and Morozova and Stolyarova (6). These works have discussed sample purity and have percentage conversions of Nb(cr) to Nb_2O_5(cr) of the order of 97% or better. Based on the discussion by Reisman and Holtzberg (1), this $\Delta_f H°(298.15\ K)$ value is for the high temperature α-phase of Nb_2O_5(cr). The heat capacity and enthalpy work, also dealing with Nb_2O_5(cr, α), indicated no phase changes for 53-297 K and 381-1785 K (14-16).

$\Delta_f G°$ values for Nb_2O_5(cr) in the range 1050-1300 K were calculated from measured emf values in an oxygen concentration cell and the known $\Delta_f G°$ values of Cr_2O_3 (17). The reported smoothed $\Delta_f G°$ values were treated by a 3rd law analysis, yielding $\Delta_f H°(Nb_2O_5$, cr, 298.15 K) = -451.6 kcal mol^{-1} with a drift equivalent to an entropy error of -4.8 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

King (14) measured the heat capacity of the high temperature α-phase Nb_2O_5 from 53.24 to 296.64 K and fitted the data (29 data points) with a combination of Debye and Einstein functions. These functions fit the data over the entire measured temperature range with a maximum deviation of 0.6% (14) and are used to calculate S°(50 K) = 2.42 cal K^{-1} mol^{-1}.

Orr (15), using the same material as King (14), measured the enthalpy from 381.4 to 1809.2 K. Gel'd and Kusenko (16) also measured the enthalpy from 461 to 1828 K. Combining these data (15, 16) with a portion of the King data (a $C_p°$ fit, then integrated), a six term polynomial fit is used to represent the enthalpy data, yielding a deviation of -0.99% to +0.81% for the Orr data and -0.64% to +1.10% for the Gel'd and Kusenko data. Two points (644 K, 734 K) of the Gel'd and Kusenko data are not used as they deviate from the polynomial-fitted values by 2-3%. Entahlpy values corresponding to temperatures greater than 1750 K but less than T_{fus} are considered to be involved in premelting (15). Enthalpy values for 1785 ≤ T ≤ 2300 K are obtained by extrapolating the values obtained from the polynomial fit. The chosen heat capacity values are obtained by differentiating the enthalpy polynomial fit for the range 298-2300 K. For temperatures 50-298 K, the King data were fit to a six term polynomial.

The existing experimental data (14, 15, 16) did not indicate any transitions other than a crystal-liquid transition. Lacking thermodynamic information for the other crystal phases of Nb_2O_5 (1), we assume that there is little difference in the heat capacity and enthalpy values for the various crystal phases. Thus the values tabulated here apply to all crystal Nb_2O_5 phases. The data for Ta_2O_5(cr) presented in these tables are treated in the same manner as discussed here so as to maintain consistency between Nb_2O_5(cr, ℓ) and Ta_2O_5(cr, ℓ).

Fusion Data

See the liquid table for details.

PREVIOUS: CURRENT: December 1972

$S°(298.15\ K) = [171.488]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1785 \pm 30\ K$

$\Delta_f H°(298.15\ K) = [-1830.873]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 104.265 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Nb_2O_5, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1785\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Orr (1) and Gel'd and Kusenko (2) reported enthalpy measurements at temperatures greater than T_{fus}. The work of Orr (1) indicates a $C_p°$ value of 57.90 cal K^{-1} mol^{-1} based on two enthalpy points in the liquid region. The three enthalpy points of Gel'd and Kusenko (2) deviate by +0.06%, -0.86%, and -0.37% from the linear representation of the Orr data. Thus, the constant $C_p°$ value of 57.90 cal K^{-1} mol^{-1} is chosen for the liquid phase. A glass transition is also chosen at 1200 K so as to ensure the proper thermodynamic relationship between crystal values and extrapolated liquid value. At temperatures below 1200 K, the heat capacity values of the crystal are used. The entropy at 298.15 K is calculated in a manner analogous to that used in calculating the enthalpy of formation.

Fusion Data

The enthalpy work of Orr (1) and Gel'd and Kusenko (2) provide information as to the heat of fusion. The heat capacity discussion for $Nb_2O_5(cr)$ and $Nb_2O_5(\ell)$ provide details as to the fitting of the data in the crystal and liquid regions. The heat of fusion is then calculated to be $\Delta_{fus}H° = 24.31 \pm 0.5$ kcal mol^{-1} at a melting point of 1785 K [$H°(1785\ K) - H°(298.15\ K) = -60.759$ kcal mol^{-1} for the crystal]. This melting point, although it is consistent with the enthalpy work (1, 2), is 21 K greater than the value reported by Holtzberg et al. (3) and is greater than most T_{fus} values cited by Charlesworth (4) and Schneider (5). Reisman and Holtzberg (6) attributed this high value of 1785 K to an impure sample. The melting point, T_{fus}, is chosen to be 1785 K strictly on the basis of being consistent with the two sets of enthalpy data. More data are necessary to accurately define consistent values for T_{fus}, $\Delta_{fus}H°$, and enthalpy values in the liquid and crystal regions.

Niobium Oxide (Nb_2O_5) Nb_2O_5(cr,l)

0 to 6000 K Ideal Monatomic Gas

IP(Ne, g) = 173929.70 ± 0.1 cm^{-1}
$S°(298.15\ K)$ = 146.327 ± 0.003 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 0 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = 0 kJ mol^{-1}

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^1S_0$	0	1

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore (1, 9). All predicted levels have been observed for n=2 and 3 but above that many predicted levels are missing. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (2) has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels; the first excited level is over 134000 cm^{-1} above the ground state. Therefore, we list the ground state only. Extension to higher temperatures may require consideration of excited states and utilization of different fill and cutoff procedures (2).

The thermodynamic functions at 298.15 K agree exactly with recent CODATA recommendations (3) except for two minor differences. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the rare gases arise due to the use of slightly different values for R; this table uses R = 8.31441 J K^{-1} mol^{-1}. Considering these minor changes, this table agrees within the estimated uncertainty with those by Hultgren et al. (4), McBride et al. (5), Gurvich et al. (8) and Wagman et al. (12). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which in this tabulation are based on the 1981 scale (6) and the 1973 values (7), respectively.

Phase Data

The triple point, 24.561 K, and boiling point, 27.102 K, are a secondary reference point and a defining fixed-point, respectively, of IPTS-68 (10, 11). Hultgren et al. (4) had recommended a triple point of 24.533 K (0.4277 atm) and a boiling point of 27.096 K (1 atm). These values are provided for the convenience of the reader and have not been evaluated by the present authors. As a result of these low values, the reference state for neon is chosen to be the ideal gas at all temperatures. This may differ from the choice of other authors.

Enthalpy of Formation

The ionization limit of neutral neon (173929.70±0.1 cm^{-1}) reported by Moore (1] is adopted as $\Delta_f H°(0\ K)$ for $Ne^+(g)$. The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ mol^{-1}, which is derived from the 1973 CODATA fundamental constants (2). The uncertainty in the ionization limit is estimated to be ±0.1 cm^{-1} which corresponds to an uncertainty of ±0.001 kJ mol^{-1} in the enthalpy of formation. Rosenstock et al. (9) and Levin and Lias (11) have summarized additional ionization potential and appearance potential data. Gurvich et al. (8) and Wagman et al. (10) adopted the same ionization potential, but the use of slightly different fundamental constants by Wagman et al. (10) resulted in a enthalpy of formation difference of 0.017 kJ mol^{-1}.

$\Delta_f H°(Ne^+, g, 298.15\ K)$ is obtained from $\Delta_f H°(Ne, g, 0\ K)$ by using IP(Ne) with JANAF (3) enthalpies H°(0 K)-H°(298.15 K) for $Ne^+(g)$, Ne(r), and $e^-(r)$. $\Delta_r H°(Ne \rightarrow Ne^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (9). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights given by Moore (4) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (5) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the $^2P_{1/2}$ level; the next lowest level is over 217000 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the $^2P_{1/2}$ state, with the energy of the latter state taken from a more recent study by Moore (1). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (5).

The thermodynamic functions reported here agree with those of Green et al. (6), Hilsenrath et al. (7), and Gurvich et al. (8) except for one or two minor differences. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard-state pressure of 1 bar, whereas the cited references used a pressure of 1 atm. Second, smaller differences arise from the use of slightly different values for the fundamental constants, the relative ionic mass, and the position of the $^2P_{1/2}$ electronic level.

NICKEL (Ni) CRYSTAL A_r = 58.69

$S°(298.15\ K) = 29.870 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_t = 631 \pm 1\ K$

$T_{fus} = 1728 \pm 4\ K$

$\Delta_f H°(0\ K) = 0\ k\ J\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_t H° = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.15 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacity values are based primarily on the studies by Keesom and Clark (1) and Busey and Giaque (2). The adopted values are actually those suggested by Busey and Giauque (2) with slight changes above 280 K so as to smoothly join the high temperature heat capacity data.

There are numerous heat capacity studies in the vicinity of the Curie point. The studies upon which our adopted values are based are as follows:

Source	Year	T, K
(3)	1938	343-1123
(4)	1955	453-1437
(5)	1965	323- 883
(6)	1966	300-1728
(7)	1966	571- 681
(8)	1970	333-1500
(9)	1971	580- 680

The adoped value for the Curie point, T_t = 631 K, is from the study of Connelly et al. (9), using an ac calorimetric method to measure relative heat capacity vlaues, and Vollmer et al. (6) using a high temperature adiabatic calorimeter.

Above 700 K, the adopted heat capacity values are those reported by Vollmer et al. (6). Below the Curie point, the above studies and that of Bronson and Wilson (203-383 K, 10) are used to construct a curve which joins smoothly with the low temperature values. The adopted table is identical (purposely) to that suggested by Mah and Pankatz (11).

Fusion Data

See the liquid table for details.

Sublimation Data

The enthalpy of sublimation, $\Delta_{sub} H°(298.15\ K)$, *is calculated as the difference between* $\Delta_f H°(298.15\ K)$ *for Ni(g) and Ni(cr).*

PREVIOUS: CURRENT: December 1976

NICKEL (Ni) LIQUID A_r = 58.69

$S°(298.15\ K) = [41.487] J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1728 \pm 4\ K$

$\Delta_f H°(298.15\ K) = [17.479]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 17.15 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Ni(ℓ) is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1728 - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

Vollmer et al. (1), using an adiabatic high temperature calorimeter with an inert gas atmosphere, measured the heat capcity of nickel in the liquid region (1728-1822 K) and reported $Cp°(\ell) = 9.32\ kcal\ mol^{-1}$. Other studies yielding liquid phase heat capacity values are: 7.86 kcal mol^{-1} by Wüst et al. (2), 9.2 kcal mol^{-1} by Umino (3), 10.3 kcal mol^{-1} by Geoffray et al. (4), and 2.58 kcal mol^{-1} by Margrave (5). This latter vlaue (5) is undoubtedly a misprint.

We adopt a constant value, $Cp°(\ell) = 9.3\ kcal\ mol^{-1}$ based on the heat capacity measurements of Vollmer et al. (1). The enthalpy study of Geoffray et al. (1393-2192 K, 4) leads to a reported heat capacity whilch is roughly 10% higher than our adopted value. The adopted value is identical to that chosen by Mah and Pankratz (6).

The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The adopted melting point, T_{fus} = 1728 ± 4 K (based on IPTS-68), is selected from the studies of Vollmer et al. (1727 K, 1), Geoffray et al. (1728 K, 4), Oriani and Jones (1727 K, 7), and Kubachewski (1730 K, 8).

The adopted enthalpy of melting, $\Delta_{fus}H° = 4.10 \pm 0.1\ kcal\ mol^{-1}$, is based on the calorimetric studies by Vollmer et al. (4.039 ± 0.060 kcal mol^{-1}) and Geoffray et al. (4.176 ± 054 kcal mol^{-1}). Other reported results are 3.31 kcal mol^{-1} by Wüst et al. (2), 4.21 kcal mol^{-1} by Umino (3), 3.32 kcal mol^{-1} by Margrave (5), and 4.4 kcal mol^{-1} by Lebedev et al. (9).

$^3F_2$	2216.519	5

Enthalpy of Formation

The enthalpy of formation for Ni(g) is obtained by an analysis of the vapor pressure data of Morris et al. (1). In this study a gas-transport method was used to measure vapor pressures (16 points) over liquid nickel in the range 1816-1895 K. For this vaporization process, we obtain $\Delta_{vap}H°(298.15\ K)$ = 99.33±1.23 kcal mol^{-1} (2nd law) and 98.54±0.12 cal mol^{-1}(3rd law). The entropy difference (2nd law-3rd law) is only -0.04±0.7 cal K^{-1} mol^{-1} which suggests good consistency between our adopted functions and the vapor pressure data. Using the 3rd law $\Delta_{vap}H°(298.15\ K)$ and $\Delta_f H°(Ni, \ell, 298.15\ K)$ (2), we calculate and adopt $\Delta_f H°(Ni, g, 298.15\ K)$ = 102.8 kcal mol^{-1}. [This is the same value chosen by Hultgren et al. (4) and Mah and Pankratz (5). Thus we maintain closer similarity with the most recent tabulations.]

Using mass spectrometric intensity data, Farber and Srivastava (3) obtained a 2nd law enthalpy of sublimation of 99.4 kcal mol^{-1} at an average temperature of 1653 K and a 2nd law enthalpy of vaporization of 92.2 kcal mol^{-1} at an average temperature of 1863 K. Using auxiliary data (2), we calculate $\Delta_f H°(Ni, \ell, 298.15\ K)$ = 102.1 kcal mol^{-1} and 99.8 kcal mol^{-1} respectively. Rutner and Haury (6) measured vapor pressures over Ni (28 points in the range 1277-1658 K), using the Langmuir technique. Their results yield a 2nd law value of 107.0±5.8 kcal mol^{-1} and a 3rd law value of 103.2±4.0 kcal mol^{-1}. The drift is -2.5±3.9 cal K^{-1} mol^{-1}. In addition Rutner and Haury (6) determined the best values of the heat of sublimation and vaporization and the parameters in a vapor pressure equation by statistically weighting nine sets of data. Although the results of this statistical treatment lead to enthalpies of formation for Ni(g) consistent with the adopted value, the results are not consistent with the melting data. Other vapor pressure studies are discussed by Hultgren et al. (4)

Heat Capacity and Entropy

The electronic energy levels and quantum weights used in the calculation are from Moore (7) and (8). Not all levels are listed above. The tabulated entropy values agree within 0.001 cal K^{-1} mol^{-1} with the recent tabulation by Hultgren et al. (4) and Mah and Pankratz (5). There are predicted levels which have not been observed and/or classified. It is not expected that $S°(298.15\ K)$ would be affected by these states, but that in the range 3000-6000K, an error of 0.2-0.3 cal K^{-1} mol^{-1} might result. In our present tabulation, the levels above 20000 cm^{-1} contribute 0.0005 cal K^{-1} mol^{-1} at 3000 K and 0.15 cal K^{-1} mol^{-1} at 6000 K to the entropy.

$^2D_{3/2}$	1606.94	4

Enthalpy of Formation

$\Delta_f H°(Ni^+, g, 0\ K)$ is calculated from $\Delta_f H°(Ni, g, 0\ K)$ (1) using the spectroscopic value of IP(Ni) = 61600 ± 10 cm^{-1} (736.90 ± 0.12 kJ mol^{-1}) from Corliss and Sugar (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Ni^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Ni, g, 0\ K)$ by using IP(Ni) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Ni(g), $Ni^+(g)$, and $e^-(g)$. $\Delta_f H°(Ni \rightarrow Ni^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Corliss and Sugar (2), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground state for $Ni^+(g)$, all levels listed by Corliss and Sugar (2), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $Ni^+(g)$, the thermodynamic functions are dependent of the estimated missing levels (for n ≥ 3) and the cut-off procedure, the Gibbs energy function shows variations of ~20% at 1000 K. We use the TEMPER-FILL cut-off procedure. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations aboue 6000 K may require consideration of the higher excited states (n > 5), and use of different fill and cut-off procedures (6).

EA(Ni, g) = 1.156 ± 0.010 eV

$S°(298.15\ K)$ = 174.577 ± 0.005 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 316.5 ± 1 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [311.764] kJ mol^{-1}

Electonic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^2D_{5/2}$	0.0	6
$^1D_{3/2}$	1470	4

Enthalpy of Formation

$\Delta_f H°(Ni^-, g, 0\ K)$ is calculated from $\Delta_f H°(Ni, g, 0\ K)$ (1) using the adopted electron affinity of EA (Ni) = 1.156 ± 0.010 eV (111.546 ± 0.965 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3).

Additional information on $Ni^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6). $\Delta_f H°(Ni^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Ni, g, 0\ K)$ by using EA(Ni) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Ni^-(g)$, Ni(g), and $e^-(g)$. $\Delta_r H°(Ni^- \rightarrow Ni + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). *$\Delta_f H°(298.15\ K)$ should be changed by* +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Ni^-(g)$ is given by Hotop and Lineberger (2, 4) and Rosenstock et al. (5) and Masey (6). The fine structure separation has been measured experimentally be laser photodetachment electron spectrometry (3) and is that recommended by Hotop and Lineberger (2).

PREVIOUS: CURRENT: June 1984 (1 bar)

$S°(298.15\ K) = 52.992 \pm 0.4\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 652 \pm 3\ K$
$T_{fus} = 1249 \pm 3\ K$

$\Delta_f H°(0\ K) = -87.13 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -87.86 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 6.443 \pm 0.4\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 30.125 \pm 2.9\ kJ\ mol^{-1}$

Enthalpy of Formation

Rosenqvist (1) studied the sulfur vapor pressure above solid nickel sulfides using the N_2/H_2S equilibrium. Combining his data for several equilibria we calculate 2nd and 3rd law values of $\Delta_f H°(298.15\ K)$ for NiS(cr) to be -20.5±0.7 kcal mol^{-1} and -22.6±3.6 kcal mol^{-1}, respectively. The stoichiometry of NiS varies from at least $NiS_{.98}$ to $NiS_{1.06}$ and Ariya et al. (2) investigated $\Delta_f H°(298.15\ K)$ in the composition range by calorimetric methods. These authors found $\Delta_f H°(298.15\ K)$ = -20.3±0.6 kcal mol^{-1} for stoichiometric NiS with an ill-defined trend toward more exothermic values at higher sulfur content. DeRanter and Breckpot (3) obtained a value of -20.08 kcal mol^{-1} for amorphous $Ni_{.98}S$ from an enthalpometric titration. We calculate $\Delta_f H°(298.15\ K)$ = -21.3 kcal mol^{-1} for the same material based on a 3rd law analysis of DeRanter and Breckpot's emf data (3).

In view of the rather large uncertainties and variations due to stoichiometry we choose to adopt the average of the five values above, $\Delta_f H°(298.15\ K)$ = -21.0±1.5 kcal mol^{-1}. This value is somewhat less negative than values of -22.1 and -22.5 kcal mol^{-1} adopted by Mah and Pankrantz (4) and Mills (5), respectively.

Heat Capacity and Entropy

The low temperature heat capacity data (52-298 K) are taken from Weller and Kelley (6). High temperature enthalpies of $NiS_{1.03}$ were measured by Conard et al. (7) via drop calorimetry. We have joined these values smoothly with the low temperature $C_p°$ measurements of Weller and Kelley to derive the $C_p°$ values from 298-652 K. Values of $C_p°$ above the transition are also taken from our analysis of Conard's et al. enthalpy data, disregarding the points above 1000 K to avoid problems due to incongruent melting. Values above 1000 K are extrapolated.

Phase Data

Both the low (β) and high (α) temperature polymorphs of NiS dissolve excess sulfur to form solid solutions. The β phase shows a limited range of homogeneity but the α phase shows a broad limit extending to approximately $NiS_{1.10}$ (8). The α phase is normally designated α-$Ni_{1-x}S$ to emphasize this feature. However, the sulfur-poor limit of this phase has the stoichiometric composition to at least 873 K; at 1070 K the deviation from stoichiometry is less than 0.05 weight percent nickel (8). Above 1079 K the deviation of the sulfur-poor limit from stoichiometry increases more rapidly and a material of stoichiometry NiS will exist as an equilibrium mixture of liquid Ni_yS_z and solid α-$Ni_{1-x}S$ (8). Thus, NiS melts incongruently.

Transition Data

We adopt 652±3 K as the transition temperature of stoichiometric NiS from rhombohedral (β) to hexagonal (α) form base on the phase diagram of Kullerud and Yund (8). The temperature of this transition is very dependent on the exact stoichiometry of the material (8). The transition enthalpy has been measured via a DTA technique by Conard et al. (7) and we adopt their value of 1.54±0.1 kcal mol^{-1}. This is considerably higher than an older value of 0.63 kcal mol^{-1} measured by Biltz et al. (9, 5) but should be much more accurate due to the calibration technique used. Mah and Pankrantz (4) estimated 0.7 kcal mol^{-1}. This transition enthalpy cannot be measured by drop calorimetry since the α form does not revert to the β form on cooling.

Fusion Data

As stated above, stoichiometric NiS will begin to form a liquid at 1079 K. The conversion to stoichiometric liquid NiS is complete at 1249 K (8). We adopt the latter as the melting point of NiS with an uncertainty estimated to be ±3K. The adopted heat of melting, $\Delta_{fus} H°$ = 7.20±0.7 kcal mol^{-1}, is from our analysis of the high temperature enthalpy data of Conard et al. (7). This value compares favorably with estimated values of 7.4 and 7.0 kcal mol^{-1} due to Nagamori and Ingraham (10) and Mah and Pankrantz (4).

PREVIOUS: CURRENT: December 1976

$S°(298.15\ K) = [72.441]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1249 \pm 3\ K$

$\Delta_f H°(298.15\ K) = [-62.474]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 30.125 \pm 2.9\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from that of NiS(cr) by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1249\ K)-H°(298.15\ K)$, between the crystal and liquid. Our 2nd and 3rd law analyses of Nagamori and Ingraham's (1) sulfur vapor pressure data yields $\Delta_f H°(298.15\ K) = -14.4 \pm 0.4$ and -16.7 ± 0.4 kcal mol^{-1}, respectively. These values agree with the adopted value within the estimated uncertainty. Meyer et al. (2) and Rosenqvist (3) conducted similar vapor pressure studies at higher and lower temperatures, respectively. Both studies qualitatively show good agreement with Nagamori at overlapping temperatures (2). However, Meyer's data are presented graphically only and Rosenqvist's data cover only compositions near $Ni_3S_2(\ell)$ and is not of high enough quality to extrapolate to the proper composition.

Heat Capacity and Entropy

The heat capacity of liquid NiS above an assumed glass transition at 860 K is taken from our analysis of the enthalpy data of Conard et al. (4). This value has a fairly high uncertainty because of the limited temperature range of the data (35 K). It is in reasonable agreement with the estimated $C°_p = 17$ cal K^{-1} mol^{-1} of Mah and Pankrantz (5). The heat capacity below the glass transition is that of the crystal. $S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Decomposition Data

The Gibbs energy data indicates that $NiS(\ell)$ will decompose to the elements, $Ni(\ell) + 1/2\ S_2(g)$, at a temperature of 2350±200 K and a fugacity of 1 atm. In view of the uncertainty in the Gibbs free energy data, computation of the exact zero point does not seem justified. Since the Gibbs energy data for $NiS(\ell)$ and NiS(g) (6) intersect at 2990±220 K, it seems clear that decomposition will occur rather than boiling.

[2269.6]	[5]
[16661.6]	[5]
[16977.8]	[3]
[17230.7]	[1]

$\omega_e = 544\ cm^{-1}$ $\omega_e x_e = 2.6\ cm^{-1}$ $\sigma = 1$
$B_e = [0.191]\ cm^{-1}$ $\alpha_e = [0.0011]\ cm^{-1}$ $r_e = [2.07]$ Å

Enthalpy of Formation

Drowart et al. (1) used a modified Knudsen cell and a mass spectrometric technique to study the equilibrium NiS(g) + Mn(g) = MnS(g) + Ni(g). Since they report no data, we adopt their value of $D_0^0 = 81.5 \pm 3.5$ kcal mol^{-1} based on their 3rd law analysis of this equilibrium. With auxiliary JANAF data (2) this yields $\Delta_f H°(298.15\ K) = 85.4 \pm 4.0$ kcal mol^{-1}. Trevedi (3) studied the absorption spectrum of NiS and determined $D_0^0 = 101.6$ kcal mol^{-1} from the onset of continuous absorption due to photodissociation. This value is likely to be too high in view of the experimental difficulties in determining the exact position of the onset of continuous absorption. Complications arise because of background emission from the furnace. A Birge-Sponer extrapolation of the vibrational data to determine D_0^0 is not meaningful since DeVore and Franzen (4) used the reverse procedure to arrive at the reported value of $\omega_e x_e$.

Heat Capacity and Entropy

No experimental information is available on the electronic structure of NiS. The electronic states are estimated to be identical to those of the Ni^{2+} ion (5) following the procedure of Brewer and Rosenblatt (6) for the transition metal oxides. As stated by Brewer and Robenblatt (6), this procedure usually overestimates the contribution of electronic states. Nevertheless, it appears to be the best method available. The uncertainty assigned to S°(298.15 K) is based mainly on the uncertainties in this approximation since the presence of the sulfide ion will undoubtedly alter the electronic structure of the nickel ion. Levels above 50,000 cm^{-1} are not included since they have a negligible effect on the thermodynamic properties. The vibrational constants are taken from a study of the matrix isolation spectrum by DeVore and Franzen (4). The rotational constants are estimated based on an oxide-sulfide correlation due to Barrow and Cousins (7), r(NiS) = 0.237 + 1.116 r(NiO). The value r(NiO) = 1.64 Å is taken from Brewer and Chandraskharaiah (8). The value of α_e is estimated assuming a Morse potential function using the expression given by Herzberg (9).

NICKEL SULFIDE (NiS_2) CRYSTAL M_r = 122.81

$S°(298.15\ K) = [71.965 \pm 8.4]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1280 \pm 5\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -131.38 \pm 16.7\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [65.689 \pm 8.4]\ kJ\ mol^{-1}$

Enthalpy of Formation

Our analysis of equilibrium data involving NiS_2 is summarized below.

Source	Reaction*	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
(1)	A	298.15	1	calorimetric	-35.1	
(2)	B	923-1033	5	-46.3±0.4	-47.1±0.1	-0.8±0.4
(3)	B	673-873	equation	-49.2	-48.7	0.7
(4)	C	500-723	2	13.9	-5.1±9.9	-31.4
(5)	C	673-873	20	-2.9±0.2	-7.5±2.4	-14.1±0.3
(6)	A	298.15	1	emf[$\Delta G°(298.15\ K)$ = -24.3)]	-25.9	

*A) $Ni(cr) + 2\ S(cr) = NiS_2(cr)$

B) $2\ Ni_{1-x}S(cr) + S_2(g) = 2\ NiS_2(cr)$

C) $Ni_{1-x}S(cr) + H_2S(g) = NiS_2(cr) + H_2(g)$

The studies due to Delafosse and Barret (4) and Rosenqvist (5) show poor agreement between 2nd and 3rd law values of $\Delta_r H°$ as well as a large 3rd law drift and are not considered further. Kullerud and Yund (7) mention that a coating of $NiS_2(cr)$ often forms on $Ni_{1-x}S(cr)$ and it seems possible that this may lead to a slow establishment of equilibrium in this system. DeRanter and Breckpot (6) state that their results may be biased for $NiS_2(cr)$ since it is a semiconductor and this may interfere in emf measurements. Consequently their results are not considered further. 3rd law results of Biltz et al. (2) and Leegaard and Rosenquist (3) yield values of $\Delta_f H°(298.15\ K)$ = -29.1±1.6 and -29.8±1.7 kcal mol^{-1}, respectively, when combined with auxiliary JANAF data (8). These values are averaged with the calorimetric value due to Ariya (1) of -35.1 kcal mol^{-1} to yield the adopted value of -31.4 kcal mol^{-1}. An uncertainty of ±4 kcal mol^{-1} is assigned due mainly to the variation in stoichiometry of one of the reactants, $Ni_{1-x}S$. The adopted value compares favorably with a value of -32.0 kcal mol^{-1} obtained by Mills (9) in a recent critical evaluation. It also compares favorably with a value of -31.3 kcal mol^{-1} calculated assuming the same contribution per gram-atom as in NiS and Ni_3S_2 (8).

Heat Capacity and Entropy

The only heat capacity measurements on NiS_2 are those of Winterberger and Bonnerot (10) at low temperature (5-10 K). Consequently the heat capacity is estimated via the following procedure. The value at 298.15 K is estimated assuming the same contribution per gram-atom as in NiS and Ni_3S_2 (8) yielding $C_p°(298.15\ K)$ = 16.88 cal K^{-1} mol^{-1}. The temperature dependence is estimated using method A of Kubaschewski et al. (11). This yields $C_p° = 15.401 + 4.960 \times 10^{-3}\ T$.

2nd law analyses of equilibrium data of Leegaard and Rosenqvist (3) and Biltz et al. (2) combined with auxiliary JANAF data (8) yield S°(298.15 K) = 16.89 and 17.60 cal K^{-1} mol^{-1}, respectively. We adopt the average of these values, 17.2 cal K^{-1} mol^{-1}, with an uncertainty estimated to be ±2 cal K^{-1} mol^{-1}. Similar analyses of studies of Delafosse and Barret (4) and Rosenqvist (5) give values of 13.10 and 29.96 cal K^{-1} mol^{-1}, respectively, but as mentioned above, these studies do not appear to be reliable since equilibrium may not have been established. A value of 19.10 cal K^{-1} mol^{-1} is obtained assuming the same contribution per gram-atom as in NiS and Ni_3S_2 (8). This is somewhat higher than the adopted value but this may be reasonable since the crystal symmetry of NiS_2 is higher (cubic) than that of NiS and Ni_3S_2 (hexagonal) (7).

Fusion Data

The melting point of $NiS_2(cr)$ is taken from the phase study by Kullerud and Yund (7). The enthalpy of melting of NiS_2 is unknown and is estimated as follows. Lewis and Randall (12) point out that the sum of the entropy of transition(s) plus the entropy of fusion is approximately constant, on a gram-atom basis, for compounds of similar structure. Using NiS and Ni_3S_2 (8) as base compounds, we calculate the above sums to be 4.06 and 4.13 cal K^{-1} g-atom^{-1}, respectively. Since NiS_2 has no known transition, we use the average value of 4.10 cal K^{-1} g-atom^{-1} to calculate $\Delta_{fus}S°(NiS_2)$ = 12.3 cal K^{-1} mol^{-1} which yields $\Delta_{fus}H°$ = 15.7 kcal mol^{-1} with an estimated uncertainty of ±2.0 kcal mol^{-1}.

NICKEL SULFIDE (NiS_2) LIQUID M_r = 122.81

$S°(298.15\ K) = [122.427]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1280 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-66.568]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [65.689 \pm 8.4]\ kJ\ mol^{-1}$

Enthalpy of Formation

There are no experimental studies of the enthalpy of formation of $NiS_2(\ell)$. Therefore, $\Delta_f H°(NiS_2, \ell, 298.15\ K)$ is calculated from that of $NiS_2(cr)$ (1) by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1280\ K)-H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to remain constant at 21.75 cal K^{-1} mol^{-1} (the value of $NiS_2(cr)$ at the melting point) above an assumed glass transition point of 960 K. Below that temperature the crystal heat capacity (1) is assumed to be valid.

$S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Decomposition Data

Under standard conditions (1 atm. pressure) the use of auxiliary JANAF data (1) indicates that $NiS_2(\ell)$ will decompose spontaneously to $NiS(\ell) + 1/2\ S_2(g)$ at all temperatures above the normal melting point. This appears to be at variance with the phase diagram of Kullerud and Yund (2) which indicates the presence of a liquid of variable composition in the Ni-S system from a stoichiometry less than Ni_3S_2 to just above NiS_2 at temperatures slightly above the melting point. However, the authors point out that this diagram does not refer to a constant pressure system and give a short discussion of the loss of sulfur to the vapor from $NiS_2(cr)$. From the sealed tube experiments of (2) it does appear that $NiS_2(\ell)$ will be stable under its own vapor pressure in a sealed tube.

Nickel Sulfide (NiS_2) Ni_1S_2(cr,l)

$S°(298.15\ K) = 133.887 \pm 0.4\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 829 \pm 3\ K$
$T_{fus} = 1062 \pm 3\ K$

$\Delta_f H°(0\ K) = -214.29 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -216.31 \pm 5.0\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 56.233 \pm 0.4\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 19.748 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Three sets of authors studied the phase equilibrium between Ni_3S_2(cr) and Ni(cr) by use of the $H_2(g)/H_2S(g)$ method (1, 2, 3). Our 3rd law analyses of the data due to Rosenqvist (1), Sudo (2) and Line and Laffitte (3) yield $\Delta_f H°(298.15\ K) = -51.6 \pm 1.0$, -50.1 ± 1.6, and -53.4 ± 1.8 kcal mol^{-1}, respectively. We adopt the average of the values, $\Delta_f H°(298.15\ K) = -51.7 \pm 1.7$ kcal mol^{-1}. Ariya et al. (4) and Vanyukov and Kiseleva (5) reported calorimetric values of -48.3 ± 0.9 and -43.3 kcal mol^{-1}, respectively. Vanuykov's value is undoubtedly incorrect since Mills (6) determined that values for FeS and MnS from the same study are approximately 25% too low. A 3rd law analysis of the emf value reported by DeRanter and Breckpot (7) yields $\Delta_f H°(298.15\ K) = -38.7$ kcal mol^{-1}. This value, however, refers to an amorphous material. At least part of the variation in values of the enthalpy of formation apparently is a result of the very wide range of stoichiometry for the high temperature phase of Ni_3S_2 (8, 9).

Heat Capacity and Entropy

The low temperature heat capacities (52-296 K) are from Weller and Kelley (10). The high temperature heat capacities are from our analysis of the high temperature enthalpy (298.15-1050 K) data of Conard et al. (11). Our analysis differs slightly from that of Conard et al. since we have forced the high and low temperature heat capacities to join smoothly at 298.15 K. Data above 1050 K are extrapolated assuming a constant heat capacity for the high temperature phase of Ni_3S_2. The thermodynamic functions show good agreement with those reported by Mah and Pankrantz (12).

The entropy at 298.15 is calculated based on an extrapolation of $S°(51\ K) = 2.06$ cal $K^{-1}\ mol^{-1}$ by Weller and Kelley (10).

Phase Data

A phase transition is observed at 829 K for Ni_3S_2 (8). Below the transition, Kullerud and Yund (8) reported the material to be stoichiometric within the limits of ±0.3 weight percent while Rau (9) reported the homogeneity range to extend over a smaller range and to the sulfur-rich side only. Above the phase transition, a wide range of homogeneity exists for $Ni_{3\pm x}S_2$ from approximately $Ni_{2.5}S_2$ to $Ni_{3.7}S_2$ (1, 8, 9). The phase diagram indicates that upon heating stoichiometric Ni_3S_2, a two phase region [$Ni_yS_z(\ell)$ + $Ni_{3\pm x}S_2$(cr)] will be encountered within a few degrees of the formation of stoichiometric liquid Ni_3S_2 (8, 9).

Transition Data

We adopt a value of 829±3 K for the phase transition from Ni_3S_2 to $Ni_{3\pm x}S_2$ based on the detailed study by Kullerud and Yund (8). This value is in fair agreement with values of 838 and 828±5 reported by Rau (9) and Rosenqvist (1), respectively. The adopted heat of transition is from our analysis of the high temperature enthalpy data of Conard et al. (11). Mah and Pankrantz (12) reported the transition at 840 K with $\Delta_f H°$ = 13.38 kcal mol^{-1} in excellent agreement with the adopted $\Delta_{trs} H°$.

Fusion Data

Kullerud and Yung (8) reported that stoichiometric Ni_3S_2 begins to melt at 1055 K with melting completed at 1062 K. The cooling curve yielded identical results. In view of the two-phase region in the phase diagram, we adopt the latter temperature as the melting point with an estimated uncertainty of ±3 K. The adopted heat of melting is from our analysis of Conard's et al. high temperature enthalpy data (11) and is in good agreement with a value of 4.70 kcal mol^{-1} reported by Mah and Pankrantz (12).

NICKEL SULFIDE (Ni_3S_2) LIQUID M_r = 240.19

$S°(298.15\ K)$ = [215.930] J K^{-1} mol^{-1}

T_{fus} = 1062 ± 3 K

$\Delta_f H°(298.15\ K)$ = [-143.926] kJ mol^{-1}

$\Delta_{fus} H°$ = 19.748 ± 0.4 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is derived from that of Ni_3S_2(cr) by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1062 K)-H°(298.15 K), between crystal and liquid. Our 2nd and 3rd law analyses of Nagamori and Ingraham's equilibrium data (1) yield $\Delta_f H°(298.15\ K)$ = -33.7 ± 6 and -33.9 ± 0.3 kcal mol^{-1}, respectively, in good agreement with the adopted value. Meyer et al. (2) and Rosenqvist (3) conducted similar studies at higher and lower temperatures, respectively. Both studies qualitatively show good agreement with Nagamori and Ingraham at overlapping temperatures (2), but Meyer's data are only presented graphically so a re-analysis is not feasible. Rosenqvist's study included compositions near, but not exactly at, the Ni_3S_2 stoichiometry. Our extrapolation of his data to the proper stoichiometry leads to a higher value of $K_p°$ at 900 K than at 800 or 1000 K. We conclude that Rosenqvist's data are not of sufficient precision for the small number of points at each temperature (3 or 4) to yield meaningful results when extrapolated.

Heat Capacity and Entropy

The enthalpy of $Ni_3S_2(\ell)$ from the melting point to 1250 K was measured by Conard et al. (4). Our analysis of these data yields the adopted constant heat capacity of 45.84 cal K^{-1} mol^{-1}. Above 1250 K the heat capacity is assumed to remain constant. This value is in good agreement with a value of 45.20 cal K^{-1} mol^{-1} reported by Mah and Pankrantz (5).

$S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Decomposition Data

There is no evidence for the existence of $Ni_3S_2(g)$. In the absence of such information we can only point out that $Ni_3S_2(\ell)$ will decompose to the gaseous elements at 3240 ± 15 K according to the Gibbs energy of formation in this table. This seems to yield an excessively long liquid range for Ni_3S_2.

PREVIOUS: CURRENT: December 1976

$S°(298.15\ K) = 186.48 \pm 16.7\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown
$\Delta_f H°(298.15\ K) = -301.11 \pm 25.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The only measured value of $\Delta_f H°(298.15\ K)$ for Ni_3S_4 is based on the emf data of DeRanter and Breckpot (1). Our 3rd law analysis of their data yields $\Delta_f H°(298.15\ K) = -71.0\ kcal\ mol^{-1}$. A value of -72.9 kcal mol^{-1} can be estimated assuming the same contribution per gram-atom in NiS and Ni_3S_2 (2). The adopted value, $\Delta_f H°(298.15\ K) = -72.0 \pm 6.0\ kcal\ mol^{-1}$, lies approximately midway between the above values and is chosen so that $\Delta_r G(629\ K) = 0$ for reaction $Ni_3S_4(cr) = 2\ NiS(cr) + NiS_2(cr)$ (2). This temperature represents the decomposition point of $Ni_3S_4(cr)$ (3, 4).

Heat Capacity and Entropy

Since there are no measured values for the heat capacity of Ni_3S_4 it is estimated as follows. The value of $C_p°(298.15\ K)$ is estimated assuming the same contribution per gram-atom as in NiS and Ni_3S_2 (2), yielding a value of 39.39 cal $K^{-1}\ mol^{-1}$. The value at the melting point is estimated assuming a contribution of 7.25 cal K^{-1} $g\text{-}atom^{-1}$ and the heat capacity is assumed to be linear between these two points (5). This leads to $C_p° = 29.153 \pm 0.03434\ T$.

The value of $S°(298.15\ K)$ is estimated assuming the same contribution per gram atom as in NiS and Ni_3S_2 (2). This estimate is subject to a rather large uncertainty since Ni_3S_4 has a spinel structure (6). Navrotsky and Kleppa (7) showed that the entropies of oxide spinels vary by ±3.7 cal $K^{-1}\ mol^{-1}$ depending on the distribution of cations among the available octahedral and tetrahedral sites.

Decomposition Data

The decomposition temperature of Ni_3S_4 is 629 ± 3 K (3, 4). It decomposes according to $Ni_3S_4(cr) = 2\ Ni_{1-x}S(cr) + NiS_2(cr)$. As mentioned above, $\Delta_f H°(298.15\ K)$ for $Ni_3S_4(cr)$ was chosen so that $\Delta_r G°(629\ K)$ for this reaction is zero. The value of $\Delta_r H°(629\ K)$ for this reaction, as calculated using auxiliary JANAF data (2), is -2.2 kcal mol^{-1}. Kullerud and Yund (4) calculate $\Delta_r H°(629\ K) = +7.0\ kcal\ mol^{-1}$ for this reaction based on the volume change as calculated from cell dimensions for the three compounds.

Phase Data

The known crystal species in the Ni-S system include NiS, Ni_3S_2, Ni_3S_4, NiS_2, and Ni_7S_6 (3). The first four species occur naturally as minerals and we have prepared JANAF Thermochemical Tables for these species (2). The species Ni_7S_6 (sometimes reported as Ni_9S_8 or Ni_6S_5) does not occur as a mineral and we have not prepared a table since there is a lack of thermochemical data. It is interesting to note that Ni_2S_3 does not occur as a stable species even though stable M_2S_3 species have been observed for Cr, Fe, and Co (8). Estimates of $\Delta_f H°(298.15\ K)$ for Ni_2S_3 range from +225 to +484 kcal mol^{-1} (9). Although Moody and Thomas (9) acknowledge large uncertainties in their calculations, they are unlikely to be in error to the extent necessary to predict stability for $Ni_2S_3(cr)$.

Enthalpy of Formation

The enthalpy of formation is based on the dissociation energy of O_2(g), 41260 ± 15 cm^{-1}(493.579±0.18 kJ mol^{-1}), as recommended by CODATA (1). This value is derived from the spectroscopic study of Brix and Herzberg (2). The products of dissociation are assumed to be oxygen atoms in their ground states. The justification for this is discussed by Gaydon (3) and Krupinie (4).

Heat Capacity and Entropy

The electronic levles for O(g) are given in the compilation by Moore (5). Our calcualtions indicate that, except for the five states lying below 34000 cm^{-1}, the inclusion of levels up to n=12 has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of these levels; the fifth excited state lies at 73768.20 cm^{-1} above the ground state. Since the inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the lowest lying status (ε_i < 34000 cm^{-1}). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic mass, the fundamental constants, and the position of the low lying electronic levles. The calculated value of S(298.15 K) is 0.0094 J K^{-1} mol^{-1} greater than that recommended by CODATA (1) due to the use of a 1 bar standard state pressure (CODATA used 1 atm). The difference is due to our use of the current CODATA fundamental constants (6). Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cut off procedures (7).

Enthalpy of Formation

$\Delta_f H°(O^+, g, 0\ K)$ is calculated from $\Delta_f H°(O, g, 0\ K)$ (1) using the spectroscopic value of $IP(O) = 109837.02 \pm 0.06\ cm^{-1}$ ($314.040 \pm 0.001\ kJ\ mol^{-1}$) from Moore (2). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, $1\ cm^{-1} = 0.01196266\ kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(O^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(O, g, 0\ K)$ by using IP(O) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for O(g), $O^+(g)$, and $e^-(g)$. $\Delta_f H°(O + O^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by $-6.197\ kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is $119837.7\ cm^{-1}$ above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

PREVIOUS: March 1977 (1 atm) CURRENT: September 1982 (1 bar)

OXYGEN, ION (O^-) IDEAL GAS M_r = 15.99995 Oxygen, Ion (O^-) O_1^-(g)

EA(O, g) = 1.4611215 ± 0.0000010 eV
$S°(298.15\ K)$ = 157.790 ± 0.001 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 105.814 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [101.846] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^2P_{3/2}$	0.0	4
$^2P_{1/2}$	177.08	2

Enthalpy of Formation

$\Delta_f H°(O^-, g, 0\ K)$ *is calculated from* $\Delta_f H°(O, g, 0\ K)$ (1) using the adopted electron affinity of EA(O) = 1.4611215 ± 0.0000010 eV (140.9757 ± 0.0001 kJ mol^{-1}). This value, is assumed to be the same as that recommended by Hotop and Lineberger (8), is based on a tunable laser photodetachment threshold study (3). Additional information on O^-(g) may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(O^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(O, g, 0\ K)$ by using EA(O) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for O^-(g), O(g), and e^-(g). $\Delta_r H°(O^- \rightarrow O + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state and the fine-structure separation (177.08 ± 0.05 cm^{-1}) for O^-(g) has been experimentally determined (3); a thorough discussion of the relevant work is given by Hotop and Lineberger (2). Massey (6) listed the hyperfine splitting of the ground state as 226 cm^{-1} based on a quadratic isoelectronic extrapolation. Use of this value would decrease the entropy at 298.15 K by 0.16 J K^{-1} mol^{-1}.

A comparison of the isoelectronic sequence - O^-(g), F(g), Ne^+(g) - would suggest that stable electronic states may exist below EA(O), i.e. below 12000 cm^{-1}. These levels would greatly affect the entropy. However, lacking any experimental evidence as to the stability of these levels, we assume no stable excited states exist.

Enthalpy of Formation

The dissociation energy of PO has been reported by various investigators to be from 5.15 eV to 7.4 eV. All of these values have been based on the spectroscopic properties of PO. Recently Drowart et al. (1) have measured the dissociation energy by a complex series of exchange reactions in a mass-spectrometer from which they calculate a dissociation energy of 142.2 ± 2.5 kcal mol^{-1} (6.17 cal K^{-1} mol^{-1}). Drowart et al. (1) also point out the agreement with the observed predissociation in the D' state. Couet et al. (2) and Verma and Dixit (3) have observed this predissociation. It was thought to occur between the 0 and 1 levels but recently Verma (4) has shown that the vibrational numbering is in error. This does not affect the predissociation, however, which we take as 49210 ± 350 cm^{-1}. If this is to ground state products, the dissociation energy is 140.7 ± 1.0 kcal mol^{-1}. The linear Birge-Sponer extrapolation (LBX) of the ground state vibrational energy levels yields D_0^0 = 164 kcal mol^{-1}, when corrected by the method of Hildenbrand (5) D_0^0 = 138.1 kcal mol^{-1}, in excellent agreement with the predissociation limit.

The much shorter extrapolation of the $B^2\Sigma^+$ levels yields D_0^0 = 157.5 (3), 155.0 (6) and 152.7 (7) kcal mol^{-1} using the LBX method, a non-linear extrapolation (8) yields 151.0 kcal mol^{-1}. All these values assume ground state atoms as the products, which must be the case since a $^2\Sigma^+$ state exists which correlates with those products and the $B^2\Sigma^+$ state must be this state or be formed by an avoided crossing. It is possible then that these values are high due to a potential maximum in the $B^2\Sigma^+$ state.

The adopted value is D_0^0 = 140.7 ± 1 kcal mol^{-1} and this yields $\Delta_f H°(PO, g, 298.15\ K) = -23.548\ kJ\ mol^{-1}$.

Heat Capacity and Entropy

The ground-state constants are from Verma (9) and Verma and Dixit (3). The ground-state splitting is from Rao (10) who also reported the excitation energy of the A state. The energy of the B state is due to Singh (11), while that of the B' state is from Verma (9). The C state energy is due to Dressler (6) while Narisimham (12) reported the C' state energy. Verma and Dixit (3) reported the D state energy and Verma (4) the D' state energy, which is considerably different from earlier reports. The E' state reported by Santaram and Rao (13) has been shown to coincide with the D' state by Verma and Dixit (3). States above 50000 cm^{-1} were not included. Other states in the 40,000 cm^{-1} region have been proposed (14) from perturbation analyses.

$\Delta_f H°(0\ K) = -217.297 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -219.409 \pm 0.8\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 0.167 \pm 0.29\ kJ\ mol^{-1}$

Enthalpy of Formation

The difference in the enthalpies of formation of red and yellow PbO has been determined directly, using a solution calorimeter, by Knacke and Prescher (1) as 394 ± 70 cal K^{-1} mol^{-1} by dissolving both forms in nitric acid. This difference and $\Delta_f H°$(PbO, yellow, 298.15 K) = -52.12 ± 0.15 kcal mol^{-1} yields $\Delta_f H°$(PbO, red, 298.15 K) = -52.51 ± 0.2 kcal mol^{-1}. Smith and Woods (2) have measured the emf of reversible cells to obtain the Gibbs energy of the reaction PbO(red, cr) + H_2(g) → Pb(cr) + H_2O(ℓ) at two temperatures. From a 2nd law analysis of these data, we obtain $\Delta_r H°$ = -15.91 kcal mol^{-1} which yields $\Delta_f H°$(PbO, red, 298.15 K) = -52.41 ± 0.2 kcal mol^{-1}.

If we assume the entropy to be accurately known, then the enthalpy of formation can be calculated directly from the Gibbs energies of reaction. Smith and Woods (2), for the reaction given above, found $\Delta_r G°$(298.15 K) = -11.513 kcal mol^{-1}, in combination with $\Delta_f G°$(H_2O, ℓ, 298.15 K) = -56.687 kcal mol^{-1} (3) yields $\Delta_f G°$(PbO, red, 298.15 K) = -45.182 kcal mol^{-1}. This Gibbs energy with JANAF entropies (4) is equivalent to $\Delta_f H°$(PbO, red, 298.15 K) = -52.45 kcal mol^{-1}. Spencer and Mote (5) measured the Gibbs energy of the reaction Pb(cr) + HgO(cr) → PbO(red, cr) + Hg(ℓ) by means of a reversible cell and obtained $\Delta_r G°$(298.15 K) = -31.265 kcal mol^{-1}. This value combined with $\Delta_f G°$(HgO, cr, 298.15 K) = -13.983 kcal mol^{-1} (4) yields $\Delta_f G°$(PbO, red, 298.15 K) = -45.248 kcal mol^{-1}, which with JANAF entropies (4) is equivalent to $\Delta_f H°$(PrO, red, 298.15 K) = -52.52 kcal mol^{-1}.

It is apparent that the data for enthalpy, Gibbs energy and entropy are all in excellent agreement, thus we adopt $\Delta_f H°$(PbO, red, 298.15 K) = -52.44 ± 0.2 kcal mol^{-1}. The adopted value was selected within all the uncertainties to assure the correct crossover of the red and yellow forms at 762 K.

Heat Capacity and Entropy

The heat capacity has been reported by King (6) from 53 to 296 K and the entropy was obtained by integration of these data based on S°(51 K) = 2.73 cal K^{-1} mol^{-1}. This extrapolated portion was obtained by use of a Debye-Einstein fit of the measured data. The value was then corrected by analogy with the 0.25 cal K^{-1} mol^{-1} difference between the extrapolation for PbO(cr, yellow) by King (6) and the measured amount. The justification for this procedure is the similarity of the two curves at all other temperatures. The high temperature heat capacities were obtained by fitting an orthogonal polynomial through the low temperature data of King (6) and the enthalpies of Spencer and Spicer (7).

Transition Data

The temperature of transition has been reported by Cohen and Addink (8) and Petersen (9). The enthalpy of transition is calculated from the adopted enthalpy at 298.15 K and the enthalpy difference, H°(762 K)-H°(298.15 K), between PbO yellow and red.

Vaporization Data

The vapor species over PbO(cr, ℓ) consists of $(PbO)_x$ where x = 1-6 (10, 11); thus a value for the heat of sublimation is not given.

PREVIOUS: March 1962 CURRENT: December 1971

LEAD OXIDE, YELLOW (PbO) CRYSTAL(YELLOW) M_r = 223.1994

$S°(298.15\ K) = 68.701 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1159 \pm 5\ K$

$\Delta_f H°(0\ K) = -216.080 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -218.062 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 25.522 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Espada et al. (1) have measured calorimetrically the heat of the reaction PbO(yellow, cr) + H_2(g) → Pb(cr) + H_2O(ℓ) as $\Delta_r H°(298.15\ K) = -16.20 \pm 0.07$ kcal mol^{-1} which yields the adopted enthalpy of formation.

Spencer and Mote (2) have measured the Gibbs energy of the cell reacton Pb(cr) + HgO(cr) → PbO(yellow, cr) + Hg(ℓ) as -31.120 kcal mol^{-1}. With JANAF auxiliary data (3) we obtain $\Delta_f G°$(PbO, yellow, 298.15 K) = -45.103 kcal mol^{-1} which corresponds to $\Delta_f H°$(PbO, yellow, 298.15 K) = -52.13 kcal mol^{-1} in excellent agreement with the adopted value.

Charette and Flengas (13) measured the Gibbs energy of formation directly in a high temperature electrolytic cell. Alcock and Belford (14) measured the Gibbs energy of the reactions (a) PbO(cr) + Ni(cr) → NiO(cr) + Pb(ℓ) and (b) Cu_2O(cr) + Pb(ℓ) = PbO(cr) + 2 Cu(cr) in high temperature electrolytic cells.

Source	T/K	$\Delta_r H°$(298.15 K), kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°$(298.15 K), kcal mol^{-1}
(13)	770-1160	-52.3	-52.93±0.26	-0.6±0.2	-52.93±0.26
(14a)	780-1070	-3.9	2.27±1.8	6.6±0.2	-54.0 ±0.7
(14b)	710-1050	-12.1	-12.61±0.25	-0.6±0.2	-52.28±0.7

These values indicate that the overall consistency between enthalpies of formation, enthalpies, entropy and Gibbs energies is generally within the experimental error.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 12.5 K to 302.7 K by Kostryukov and Morozova (4) and from 54.1 K to 296.1 K by King (5). The two sets of data are in reasonable agreement with differences of up to 0.5%. A line fitted through both data sets yields an entropy within the stated uncertainty of the Russian set, whose results we adopt.

The high temperature heat capacity was derived from the enthalpy measurements of Rodigina et al. (6) by curve fitting with orthogonal polynomials. The curve was constrained to join smoothly with the low temperature heat capacities. The adopted values are in good agreement with enthalpies reported by Regnault (7), Magnus (8) and Kopp (9). The enthalpies reported by Spencer and Spicer (10) lie about 3% higher than the adopted values are are admitted to be not too accurate. The values reported by Knacke and Prescher (11) lie 5 to 8% higher than the adopted values.

Fusion Data

The melting point was selected by Schaedier (12) in his review of metal oxide melting points. The enthalpy of melting was calculated from the enthalpy equations derived from the work of Rodigina et al. (6) for crystal and liquid. Knacke and Prescher (11) report a heat of melting of 6.57 kcal mol^{-1} from their enthalpy measurements.

$S°(298.15\ K) = [73.376]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1159 \pm 5\ K$

$\Delta_f H°(298.15\ K) = [-202.249]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 25.522 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from that of PbO (yellow, cr) by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(1159 K)-H°(298.15 K), between PbO(yellow, cr) and PbO(ℓ). Direct measurements of the Gibbs energy change in the reaction PbO(ℓ) + C(cr) → Pb(ℓ) + CO(g) have been reported by Kvyatkovskii et al. (1). Charette and Flengas (2) and Delimarskii and Andreeva (3) have also determined the Gibbs energy of formation of the liquid directly in a high temperature cell. 2nd- and 3rd-law analysis of these data are summarized below.

Source	T/K	$\Delta_r H°$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°$(PbO, ℓ, 298.15 K) kcal mol^{-1}
(1)	1173 - 1423	34.5 ± 6.5	22.81 ± 2.49	-8.6 ± 4.9	-48.20 ± 2.5
(2)	1160 - 1371	-49.9 ± 0.2	-49.24 ± 0.13	0.5 ± 0.1	-49.24 ± 0.13
(3)	1173 - 1253	-46.9 ± 5.6	-48.51 ± 0.39	-1.5 ± 4.6	-48.51 ± 0.39

Heat Capacity and Entropy

The heat capacity was obtained from the enthalpy determinations of Rodigina et al. (4) and Knacke and Prescher (5). The absolute enthalpy values differ by 2-3% but the constant heat capacities derived from each set agree very well. The entropy at 298.15 K is calculated from that of the yellow crystal in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the yellow-crystal table for details.

Vaporizaton Data

See the red-crystal table for details.

Enthalpy of Formation

A value for the dissociation energy can be calculated by applying the Hildenbrand formula (1) to the linear Birge-Sponer extrapolation of the ground state vibrational levels. This procedure yields a D° = 91.4 kcal mol^{-1}, corresponding to $\Delta_f H°(0\ K)$ = 14.5 kcal mol^{-1}.

Recently, Singh and Nair (3) have calculated D_0^0 = 99.2 kcal mol^{-1} from a special potential energy curve which takes into account the electronegativity of the atoms.

The enthalpy of sublimation of PbO(yellow, cr) to monomeric PbO has been measured mass-spectrometrically by Drowart et al. (2). Our analysis of their vapor pressure data yields $\Delta_{sub}H°(298.15\ K)$ = 68.9 ± 1.5 kcal mol^{-1}, which yields $\Delta_f H°(PbO, g, 298.15\ K)$ = 16.8 ± 1.7 kcal mol^{-1}. This value is adopted and corresponds to a dissociation energy at 0 K of 88.6 kcal mol^{-1}.

Heat Capacity and Entropy

The tabulated molecular and electronic constants are taken from Barrow et al. (4). The state designations are those used by Barrow et al. who interpret the spectra in terms of type c coupling, when the state designations Σ, Π, etc. no longer have meaning. The estimated values for $\omega_e x_e$ for the C' and E states were obtained from the B_e values by averaging the $\omega_e x_e/B_e$ ratio for the known states. The functions were calculated from the partition function $Q = Q_t \sum_i Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$, the values for Q_r^i and Q_v^i were calculated with first-order anharmonic corrections.

Enthalpy of Formation

The selection for $\Delta_f H°(0\ K)$ of SO(g), 1.2 ± 3 kcal mol^{-1}, was derived from one of the two independent means, pointed out by Okabe (1) that employs principally spectroscopic data: $\Delta_f H°(SO, g, 0\ K) = 1/2\ D_0^0(S_2) + 1/2\ D_0^0(O_2) - D_0^0(SO) + 1/2\ \Delta_f H°(S_2, g, 0\ K)$. The data employed are as follows. Ricks and Barrow (2) give $D_0^0(S_2) = 100.69 \pm 0.01$ kcal mol^{-1}. Brix and Herzberg (3) give $D_0^0(O_2) = 117.97 \pm 0.046$ kcal mol^{-1}. On the basis of analysis of spectroscopic data to 1964, JANAF (4) gives $D_0^0(SO) = 123.5 \pm 0.3$ kcal mol^{-1}. NBS (5) gives $\Delta_f H°(S_2, g, 0\ K) = 30.65 \pm 0.2$ kcal mol^{-1}. Assuming the dissociation products of SO are $S(^1D_2)$ and $O(^3P)$, Colin (6) concludes $D_0^0(SO) = 123.56 \pm 0.23$ kcal mol^{-1}. A systematic error of 0.65 kcal mol^{-1} is incurred if the assumption is wrong. Support for this assumption is as follows: 1) Okabe (7) concludes that $D_0^0(OS-O) = 130.06 \pm 0.5$ kcal mol^{-1} assuming the predissociation of SO_2 is to ground state products. Using $\Delta_f H°(SO_2, g, 0\ K) = -70.336$ kcal mol^{-1} from (5) and the relation: $\Delta_f H°(SO, g, 0\ K) = D_0^0(OS-O) - 1/2\ D_0^0(O_2) + \Delta_f H°(SO_2, g, 0\ K)$, one obtains $\Delta_f H°(SO, g, 0\ K) = 0.7 \pm 0.7$ kcal mol^{-1}; 2) Assuming the threshold energy for fluorescence of SO, 217.00 ± 0.7 kcal mol^{-1} (see Okabe (8)), corresponds to the minimum energy for the reaction $OSCl_2 = SO(A^3\Pi_0) + 2\ Cl(^3P_{3/2})$ and using 108.43 kcal mol^{-1} for the difference in energy between the lowest vibrational levels of $SO(A^3\Pi_0)$ and $SO(X^3\Sigma^-)$ (Colin (6)) one obtains $\Delta_f H°(SO, g, 0\ K) = 1.3 \pm 0.7$ kcal mol^{-1}. This is based on $\Delta_f H°(OSCl_2, g, 0\ K) = -50.07$ kcal mol^{-1} (5) and $D_0^0(Cl_2, 0\ K) = 57.177 \pm 0.005$ kcal mol^{-1} given by Douglas et al. (9); 3) Re-examination of the photoionization-yield curves of SO_2^+ and SO^+ obtained by Dibeler and Liston (10) suggests that their reported threshold for $SO + SO^+ + O + e^-$ should be increased from 15.81 ± 0.02 cal K^{-1} mol^{-1} to 16.00 eV. Using the latter and the ionization energy of SO given by Jonathon et al. (11) of 10.34 ± 0.02 eV and the relation $\Delta_f H°(SO, g, 0\ K) = D_0^0(S-O) - 1/2\ D_0^0(O_2) + \Delta_f H°(SO_2, g, 0\ K)$, one obtains $\Delta_f H°(SO, g, 0\ K) = 1.20 \pm 0.5$ kcal mol^{-1}.

Heat Capacity and Entropy

The vibrational and rotational constants of the respective electronic levels were taken from Rosen (12). The thermodynamic functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \Sigma Q_r^i Q_v^i g_i \exp(-c_2\epsilon_i/T)$. The National Bureau of Standards prepared this table (13) by critical analysis of data existing in 1972. Using molecular constants and $\Delta_f H°$ selected by NBS (13), we recalculate the table in terms of 1973 fundamental constants (14), 1975 atomic weights (15), and current JANAF reference states for the elements.

Product of the Moments of Inertia: $I_A I_B I_C = 6.270091 \times 10^{-115}\ g^3\ cm^6$

Enthalpy of Formation

There is no direct measurement of the standard enthalpy of formation for $S_2O(g)$. Blukis and Myers (1) have discussed the discrepancy of the values of $\Delta_f H°(0\ K)$ which vary from -1 to -35 kcal mol^{-1}. Hagman (2) reported $\Delta_f H° = -17$ kcal mol^{-1} from his ionization and appearance potential measurements by mass spectrometry. Steudel and Schenk (3) estimated the enthalpy of formation as -22.7 kcal mol^{-1}. If the bond dissociation energies $D_0^0(S-O) = 123.5$ kcal mol^{-1} and $D_0^0(S-S) = 101$ kcal mol^{-1} were used to estimate the dissociation energy of S_2O (i.e., $D_{0_1}^0(S_2O) = 224.5$ kcal mol^{-1}), one will obtain $\Delta_f H = -35.3$ kcal mol^{-1}. Jones (4) reported the predissociation energy, 91 kcal mol^{-1} for sulfur monoxide from the infrared and ultraviolet spectra. [Meschi and Myers (5) have concluded from their experiment that the so-called sulfur monoxide is S_2O.] Therefore, if SO(g) + S(g) were the dissociation products, the $\Delta_f H°$ would be -25.4 kcal mol^{-1} and if $S_2(g)$ + O(g) were the products, the $\Delta_f H°$ would be -1.2 kcal mol^{-1}. (All JANAF auxiliary data used in calculation.)

Dewing and Richardson (6) have investigated the gas phase equilibria in the sulfur-oxygen vapor at 1250° and 1500°C, respectively. Blukis and Myers (1) recalculated their data based on the assumption that the S_2O (instead of SO) was the major product in the equilibrium, and obtained $\Delta_f H° = -13$ kcal mol^{-1} for $S_2O(g)$ which is adopted in this table.

Heat Capacity and Entropy

The bond distance, angle, and vibrational frequencies were obtained from the microwave and infrared spectra measurements by Meschi and Myers (5) and Blukis and Myers (1). The principal moments of inertia are: $I_A = 2.0209 \times 10^{-39}$, $I_B = 16.6326 \times 10^{-39}$ and $I_C = 18.6536 \times 10^{-39}$ g cm^2.

SILICON OXIDE (SiO) — *IDEAL GAS* — M_r = 44.0849

$S°(298.15\ K) = 211.579\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -101.57 \pm 8.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -100.42 \pm 8.4\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State $^1\Sigma^+$	ε_i, cm^{-1}	g_i
	0	1
	[30000]	6
	42640	2

ω_e = 1241.44 $\quad \omega_e x_e$ = 5.92 $\quad \sigma$ = 1

B_e = 0.7273 $\quad \alpha_e$ = 0.00508 $\quad r_e$ = 1.509 Å

Enthalpy of Formation

The adopted value is based on equilibrium data summarized below. The more reliable results from three different reactions lie in the range from about -23 to -28 kcal mol^{-1}. Extreme values, including -20 and -32 kcal mol^{-1}, can be discounted on experimental grounds. Margrave (1) recently reported $\Delta_r H°(298.15\ K)$ = 82.8±1.5 kcal mol^{-1} for 0.5 SiO_2(s) + 0.5 Si(s) = SiO(g), but details are not yet available. *Assuming that this corresponds to reaction A below, we calculate* $\Delta_f H(298.15\ K)$ = -25.4 kcal mol^{-1}. Reaction A involves the nominal composition SiO(s) which is treated as an intimate mixture of 0.5 Si(cr) + 0.5 SiO_2(high cristobalite). X-ray studies (13, 14) suggest that the condensed "SiO" used in (4, 8) is probably a mixture of Si and amorphous or vitreous SiO_2. The adopted $\Delta_f H°$ corresponds to D_0^0 = 190±3 kcal mol^{-1}. This may be compared with D_0^0 = 179 kcal mol^{-1} obtained by linear Birge-Sponer extrapolation of the ground state vibrational constants and with D_0^0 = 185±7 kcal mol^{-1} obtained by Barrow (15) from D_0^0(LBX) = 77.5 kcal mol^{-1} for the excited state at 52580 cm^{-1}. Barrow assumed $D_0^0/D_0'^0$(LBX) = 0.456 based on related molecules.

A) 0.5 SiO_2(high cristo.) + 0.5 Si(cr, ℓ) = SiO(g)

B) SiO_2(high cristo.) + H_2(g) = H_2O(g) + SiO(g)

C) SiO_2(high cristo.) = 0.5 O_2(g) + SiO(g)

D) SiO_2(ℓ) + Mg(g) = MgO(cr) + SiO(g)

*Starting material was "SiO" **Starting material was tridymite ***Starting material was quartz

Heat Capacity and Entropy

All constants for the ground state and the $A^1\Pi$ State at 42640 cm^{-1} are taken from the analysis of the A-X system reported by Lagerqvist (16). An intercombination transition has been observed and assigned as $^1\Sigma^- \leftarrow a^3\Pi_r$ by Verma (17). The value of the a-X excitation energy is unknown but is estimated here as 30000±5000 cm^{-1} by comparison with the a and A states of CO and AlCl. Several additional states are known (15, 16) to lie near or above the A state, but they are omitted because their contribution to the thermal functions is negligible.

PREVIOUS: September 1967 (1 atm) CURRENT: September 1967 (1 bar)

$S°(298.15\ K) = 55.522 \pm 0.4\ J\ K^{-1}\ mol^{-1}$
$T_{fus} = 2938 \pm 20\ K$

$\Delta_f H°(0\ K) = -589.801 \pm 3.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -592.036 \pm 3.3\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [75.312]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is from (1). The adopted value was derived (2) from $\Delta_r H° = -198.1$ kcal mol^{-1} for $SrCl_2$(cr), $\Delta_{sol} H°$ of $SrCl_2$ in HCl(aq), and calorimetric data for $\Delta_r H°$ of SrO(cr) + (x+2)HCl(n H_2O) → [$SrCl_2$(aq) + H_2O(aq) + x HCl(n' H_2O)]. Data of Adami and Conway (3) yield $\Delta_f H°$(SrO, cr) = -141.3 kcal mol^{-1}, while those of Monaenkova and Vorob'ev (4) yield =141.7 kcal mol^{-1}. Flidlider et al. (5) derived -140.5 kcal mol^{-1} from their (unpublished) data for SrO(cr) and similar measurements for Sr(cr) by Guntz and Benoit (6). Brisi and Abbattistra (7) omit the mole ratios necessary for treatment of their data, but an approximate calculation suggests consistency with the adopted value. We omit from this discussion the early data which Parker (1, 2) reviewed in selecting the adopted value.

Direct measurements of $\Delta_c H°$ of Sr(cr) by Mah (8) gave -144.44 ± 0.4 kcal mol^{-1}. The negative bias of about 3 kcal mol^{-1} presumably resulted from inadequate allowance for side reactions, e.g., with combustion products of Mylar used to contain the Sr. Parker (2) noted that the combustion value is incompatible with data for $SrCl_2$(cr) and related compounds. We find that the combustion value is also less consistent with equilibrium data for $SrCl_2$(ℓ and g). There is a similar, but much larger, discrepancy for Ba compunds (cf, BaO, crystal). Although impurity effects are of concern in all studies, the evidence predominantly favors the solution calorimetry.

Heat Capacity and Entropy

$C_p°$ is based on data (1.4-310 K) of Gmelin (9) who reported smoothed values only in the range 4 to 300 K. Based on Gmelin's graphs, we have corrected several typographical errors and resmoothed $C_p°$ above 250 K where the scatter increases significantly. The entropy is obtained by integration of our adopted $C_p°$ using S° = 0.0003 cal K^{-1} mol^{-1} at 4 K. Gmelin reported S°(273.15 K) = 12.40 ± 0.02 cal K^{-1} mol^{-1} compared with 12.33 from our integration. $C_p°$ data (58-298 K) of Anderson (10) are lower at all temperatures with deviations ranging from -4.7% (61 K) to -0.3% (223 K) and -0.7% (298 K).

$C_p°$ above 300 K is from constrained fitting of enthalpy data (363-1266 K) of Lander (11). The calorimeter (11) was calibrated with Pt, but details are lacking to assess the bias due to minor changes in the enthalpy of Pt (12). Deviations of Lander's data from the adopted curve range from -0.7 to +1.1%.

Fusion Data

See the liquid table for details.

STRONTIUM OXIDE (SrO) LIQUID M_r = 103.6194

$S°(298.15\ K) = [80.846]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2938 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [-517.292]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [75.312]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(SrO, ℓ, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2938 K)-H°(298.15 K), between the crystal and the liquid.

Heat Capacity and Entropy

$C_p°$ of the liquid is estimated as β cal K^{-1} g-atom^{-1} by comparison with other oxides. $C_p°$ is taken from the crystal in the range from 298 K up to the glass transition assumed at 2000 K. S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°$.

Fusion Data

Foex (1, 2) obtained T_{fus} = 2660°C from a solar-furnace study using SrO as its own container. We adopt this result but increase it by 5 for conversion to IPTS-68. The much lower value (2420°C) of Schumacher (3, 4) probably resulted from contamination by WO_3 from tungsten supports of the sample. $\Delta_{fus}H°$ is estimated such that $\Delta_{fus}S°$ is 6 cal K^{-1} g-atom^{-1}. Phase data for the binary system SrO-$SrZrO_3$ (2) yield $\Delta_{fus}H° = 10 \pm 2$ kcal mol^{-1} assuming ideal behavior in the liquid. Comparison with the very non-ideal behavior of other mixed oxides suggests that the SrO data (2) are not inconsistent with $\Delta_{fus}H° = 18$ kcal mol^{-1}.

Enthalpy of Formation

We adopt D° = 101.0 ± 4 and $\Delta_f H°(298.15\ K) = -3.2 \pm 4$ kcal mol^{-1} based on the equilibria analyzed below. Greatest weight is given to the conventional mass-spectrometric studies (7, 8). We give "<" or ">" for the resulting D° values which we feel may be biased. The JANAF differences in $\Delta_f H°(298.15\ K)$ for MoO_3-MoO_2 and WO_3-WO_2 may be biased by ~4 and ~-3 kcal mol^{-1}, respectively; this would cause bias of the opposite sign in D° values derived from reactions C and D. With these adjustments, our analyses would be comparable with those of Brewer and Rosenblatt (10) based on a $^1\Sigma$ ground state.

Less reliable data were reviewed by Drowart et al. (8) and Schofield (11). Subsequent studies include two new techniques: nonisothermal Langmuir mass-spectrometry (9) and crossed-beam reaction threshold (12). The former yields D° = 98.3 and >96 kcal mol^{-1} (see reactions E and F below). JANAF data for the reaction SrO(cr) = Sr(g) + O(g) suggest that the P_0 assumed (9) for reaction F is too large. JANAF pressures for Sr(g) and O(g) may be combined with the estimated composition (3) of 5% SrO(g) to calculate $K_p°$ for reaction F and D° = 93.5 ± 8 kcal mol^{-1}. D° would increase to 97 kcal mol^{-1} if the beam in the magnetic-deflection experiment (3) contained 10% SrO(g) rather than 5%. The crossed-beam reaction (12) was interpreted to give D° = 112.5(+3.5 to -0.71 kcal mol^{-1}. We assume this value has a positive bias. Finally, Kalff (13) used spectrometry of CO-N_2O flames to derive D° = 93.6 ± 2.3 kcal mol^{-1}. This value becomes ~99 kcal mol^{-1} when adjusted to be consistent with the JANAF free energy functions.

[b]Nonisothermal. [c]$P_0 = 0.4273 P_{Sr}$ assumed.

Heat Capacity and Entropy

Electronic levels (T_0) and vibrational-rotational constants of the observed states are from Field (1) and Rosen (4). The long-sought $a^3\Pi$ and $A^1\Pi$ states of CaO, SrO and BaO were characterized by Field (1) using a new method for assignment of perturbations. This study resolved the long-standing controversy over low-lying electronic levels and confirmed (1) that $X^1\Sigma^+$ is the ground state (3). We estimate the other potentially low-lying state ($^3\Sigma^+$) at 8000 cm^{-1} by assuming that it lies 3000 ± 2500 cm^{-1} (1, 5) below the isoconfigurational A state. Other predicted states and thier vibrational-rotational constants are estimated in isoconfigurational groups by comparison with BeO, MgO, CaO and BaO (5). Comparisons are facilitated by listing the states in the isoconfigurational order of MgO (5, 6). Our thermodynamic functions correspond to an "effective" ground state with 1<g<2 instead of g = 2 (11). Our functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \sum_i Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$.

Enthalpy of Formation

Based on the adopted ground state vibrational constants, a linear Birge-Sponer extrapolation yields D_0^0 = 9.28 eV (214.02 kcal mol^{-1}). Applying a correction for the ionicity in the Ta-O bond (1), we recalculate D_0^0 = 8.57 eV (199.94 kcal mol^{-1}). This in turn leads to $\Delta_f H°(TaO, g, 298.15\ K)$ = 45.52 kcal mol^{-1}, using auxiliary data (2).

Inghram et al. (3) and Krikorian and Carpenter (4) have presented mass spectrometric evidence indicating that the predominant vapors in the vaporization of Ta-Ta_2O_5 mixtures in Ta Knudsen cells are TaO and TaO_2.

*Recalculated pressures using Otvis and Stevenson method for estimating ionization cross sections (4, 5).

A: 0.6 Ta(cr) + 0.2 Ta_2O_5(cr) = TaO(g) B: 0.6 Ta(cr) + 0.2 Ta_2O_5(ℓ) = TaO(g) C: Ta(cr) + 1/2 O_2(g) = TaO(g)

The discrepancies here are rather severe and indicate considerable uncertainty in the system studied. In addition to the standard difficulties in a Knudsen cell system and the subsequent assumptions used for a 2nd and 3rd law analysis, there is an additional problem of oxygen diffusing through the walls of the Ta Knudsen cell, followed by volatilization of TaO(g) from the outer surfaces (4, 6). Based on JANAF values for Ta_2O_5(cr) and Ta_2O_5(ℓ), $\Delta_r H°(298.15\ K)$ for reaction (A) should be 4.25 kcal mol^{-1} more positive than reaction (B). The 3rd law results of Krikorian and Carpetner (4) for reactions (A) and (B) differ by 2.57 kcal mol^{-1} but the 2nd law results differ by 3.73 kcal mol^{-1} in the wrong direction. The 3rd law results of Inghram et al. (3) differ by 2.50. It is interesting to note that if the pressures reported by Krikorian and Carpetner (4) are multiplied by a factor of 1000, a 3rd law analysis yields results in excellent agreement with the 3rd law results of Inghram et al. (3). 2nd law values would still be in disagreement, however, and serious 3rd law drifts would still be present. Drowart et al. (16) observed the vapors over a Ta wire at various oxygen pressures in the range 1900-2900 K. Our analysis of their graphically displayed results does not clarify the situation as there is again a large 3rd law drift. Inghram et al. (3) also measured the ion currents corresponding to ZrO(g) and TaO(g) over mixtures of ZrO_2(cr) and Ta(cr) in a Ta Knudsen cell. The reaction was stated as ZrO_2(cr) + Ta(cr) = ZrO(g) + TaO(g). A 2nd law analysis of seven data points yielded $\Delta_r H°(2200\ K)$ = 317 ± 7 kcal mol^{-1} as reported by Inghram et al. (3). Using auxiliary data (2), this leads to $\Delta_f H°(TaO, g, 298.15\ K)$ = 51 ± 12 kcal mol^{-1}, where +12 kcal mol^{-1} reflects the additional uncertainty in $\Delta H°(298.15\ K)$ for ZrO(g). Goldstein et al. (7), in studying the vaporization of Nd_2O_3 from Ta Knudsen cells in the range 2040-2450 K, determined the enthalpy of reaction for Nd_2O_3(cr) + Ta(cr) = 2 NdO(g) + TaO(g). They reported D_0^0 = 9.36 ± 0.2 eV for TaO(g). This leads to $\Delta_f H°(TaO, g, 298.15\ K)$ = 29.6 ± 5.0 kcal mol^{-1}.

Brewer and Rosenblatt (17) have suggested Gibbs energy functions which are 1.38 to 2.14 cal K^{-1} mol^{-1} more positive than those adopted here. The reason for the difference is that Brewer and Rosenblatt (17) based their functions on low lying electronic states as observed in Ta^{++}(g). The $\Delta_f H°(298.15\ K)$ values derived from the 3rd law would increase by roughly 3.5-4.2 kcal mol^{-1} with the drift becoming more positive by 2-3 cal K^{-1} mol^{-1} if we were to use Brewer and Rosenblatt's valves.

Due to the large scatter in the mass spectrometric results, we prefer not to average the resulting $\Delta_f H°$ values but to rely on correlations with VO(g) and NbO(g). There has been good agreement for VO(g) and NbO(g) between the adopted JANAF $\Delta_f H°(298.15\ K)$ value and the value derived from the Birge-Sponer result corrected for ionicity (2). Thus we adopt $\Delta_f H°(TaO, g, 298.15\ K)$ = 46.0 ± 15.0 kcal mol^{-1}, which is a rounded value based on the adjusted Birge-Sponer result. This corresponds to D_0^0 = 8.65 ± 0.65 eV.

Heat Capacity and Entropy

The band spectrum attributable to TaO(g) has been observed by many investigators (8-13). Weltner and McLeod (14) studied TaO spectroscopically in the infrared, visible, and near-ultraviolet regions by means of matrix isolation techniques. Sixteen electronic transitions were observed from the $X^2\Delta_{3/2}$ state, determined to be the ground state. Cheetham and Barrow (15) characterized nineteen electronic states from a rotational analysis of the emission spectrum of TaO in the region 2740-9500 Å. The combination of the results of these latter two studies as given by Cheetham and Barrow (15) provides the adopted vibrational and rotational constants as well as the electronic levels. Cheetham and Barrow (15) indicated the possibility of other low lying states based on the early work by Kiess and Stowell (8).

The electronic states listed by Cheetham and Barrow (15) are actually sublevels as indicated by the Ω value. The quantum weight of 2 is assigned if the two sublevels which are part of the same state are present (i.e. similar ω_e and $\omega_e x_e$ values of rthe same Δ state but different Ω value). If the two sublevels of a particular Δ state are not accounted for, then a quantum weight of 4 is assigned to that sublevel which is tabulated.

PREVIOUS: December 1973 (1 atm) CURRENT: December 1973 (1 bar)

TITANIUM OXIDE, ALPHA (α-TiO) CRYSTAL M_r = 63.8794

$S°(298.15\ K) = 34.769 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

T_{trs} = [1265] K

$\Delta_f H°(0\ K) = -539.668 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -542.665 \pm 12.6\ kJ\ mol^{-1}$

$\Delta_{trs} H° = [4.2]\ kJ\ mol^{-1}$

Enthalpy of Formation

Recent data tend to support our speculation (1) that previous calorimetric data refer to ill-defined states of TiO(α, β). New combustion calorimetry (2) at 1100 K gave $\Delta_f H°(298.15\ K) = -129.9 \pm 1.1\ kcal\ mol^{-1}$ which is ~5 kcal mol^{-1} more negative than two earlier combustion studies (3, 4) near room temperature. The difference was attributed (2) to use of samples consisting of α-phase (2) or mainly β-phase (3, 4). This interpretation is reasonable but unproved; it is neither confirmed nor refuted by incomplete published descriptions of the samples. Previously, the samples (3, 4) were assumed to be α-phase since similar material gave a discontinuity in enthalpy data above 1200 K.

Lyon (5) proposed that $\Delta_f H°$ may be affected by vacancy concentration, which varies from ~14 to 15% (5) in samples of stoichiometric β-TiO obtained at normal pressure. Samples with vacancy concentrations dow to 0% have been prepared (6) at high pressure. PVT data (6) allowed calculation (5) of values of $\Delta_f H°$ for TiO(β, 0% vacancies) → TiO(β, 14% vacancies). These values, if valid, suggest that $\Delta_f H°$ should be quite different for vacancy-free β-TiO and significantly different even for the normal range of vacancy concentrations. Ideal ordered α-TiO, containing 1/6 or 16.7% vacancies, should involve additional changes in volume (5) and $\Delta_f H°$. In summary, the discrepancy in $\Delta_f H°$ may arise from sample differences - phase, composition and vacancy concentration - or from bias in the reaction calorimetry.

Our choice of $\Delta_f H°$ is influenced by $\Delta_f G°$ values derived from oxygen potentials (7, 8) over TiO_x ($0 < x < 1.5$). We use solid-state emf data (7) for many compositions in the range $0.6 < x < 1.6$; these are converted to $\Delta_f \bar{G}(O_2)$ with the authors' results (7) for the reference couples Ta/Ta_2O_5 and "$TiO_{1.3}$", the integrated over appropriate ranges of x in order to obtain $\Delta_r G°$. For reaction C relating TiO(β) to Ti_2O_3 we obtain $\Delta_r G°$ = -38.20(1300 K), -37.49(1400 K), -36.82(1500 K), -36.180(1600 K) and -35.52(1700 K) kcal mol^{-1} with an estimated uncertainty of ±1 kcal mol^{-1} (~3%). Combination with $\Delta_f G°$ (9) of Ti_2O_3 yields $\Delta_f G°$(TiO, β) = -131.5 + 23.5 (T/1000); hopefully, the uncertainty does not exceed 1.5 kcal mol^{-1}, based on a revised uncertainty of 1 kcal mol^{-1} for Ti_2O_3.

Approximate values of $\Delta_f G°$(TiO) may be derived from $TiO_{0.334}$(cr) and Ti(cr). Calorimetric data (10) yield $\Delta_f G°(TiO_{0.334})$ = -46.1 + 8.40 (T/1000) for 1200 < T < 1700; this equation excludes the added disordering entropy (10) which now is known to be included, at least partially, in order-disorder transitions of the alloy near 800 K (11). $\Delta_f \bar{G}(O_2)$ in the range $0.334 < x < 0.5$ is approximated by limiting values, i.e., the mean from $x < 0.334$ and the univariant value (7) at x = 0.6, in order to get negative and positive limits for $\Delta_f G°$(TiO). These limits differ by 1 to 2.5 kcal mol^{-1} at 1300 to 1700 K; mean $\Delta_f G°$ values are -102.0 (1300 K), -96.8(1400 K), -92.6(1500 K), -89.3(1600 K) and -86.0 kcal mol^{-1}(1700 K). Equilibration with Ca/CaO and Mg/MgO (8) near 1200 K gave $\Delta_f \bar{G}(O_2)$ for $x < 0.3$; we combine these by interpolation with values (7) at $x > 0.6$ to give $\Delta_f G°$(TiO) = -107.3(1173 K), -106.6(1200 K) and -103.8 kcal mol^{-1}(1273 K). $\Delta_f G°$ values derived from Ti(cr) and $TiO_{0.334}$(cr) are relatively uncertain, perhaps by 5 kcal mol^{-1}, due to gaps in $\Delta_f \bar{G}(O_2)$ and to greater uncertainty in emf and x.

$\Delta_f H°$ values from $\Delta_c H°$ and from 3rd law analyses of $\Delta_r G°$ are compared below. $\Delta_f H°$ from Ti_2O_3 (7, 9) is consistent with the new $\Delta_c H°$ (2) but ~5 kcal mol^{-1} more negative than the earlier value (3) which we assume to refer to β-TiO. $\Delta_f H°$ from Ti_2O_3 (7, 9) and from $\Delta_c H°$ (3) could be made consistent if, as proposed by Charlu et al. (2), $\Delta_t S°$ and S°(β) were increased by 3 cal K^{-1} mol^{-1} [see β-TiO (9)]. If (3) instead of (2) were correct for α-TiO, $\Delta_f \bar{G}(O_2)$ would have to be 14% larger than observed. The more uncertain $\Delta_f H°$ from $TiO_{0.334}$ (7, 9) is very temperature dependent (large δS); it agrees with (2) at 1350 K and with (3) at 1700 K. $\Delta_f H°$ from Ti (7-9) is even more negative than (2). We adopt $\Delta_f H°$ = -129.7 kcal mol^{-1} but increase the uncertainty to +3 kcal mol^{-1} to allow for possible uncertainties in the samples.

Heat Capacity and Entropy

$C_p°$ is from data (52.6-296 K) of Shomate (12) and enthalpy data (357-1771 K) of Naylor (13). S°(298.15 K) = 8.31 cal K^{-1} mol^{-1} is calculated from $C_p°$ based on S°(50 K) = 0.23 cal K^{-1} mol^{-1}. Ideal, ordered α-TiO should have no configurational entropy at T/K = 0 (14). We assume that $C_p°(\alpha) = C_p°(\beta)$ and fit the enthalpy data (357-1200 K and 1273-1771 K) by a single curve after subtracting the apparent $\Delta_{trs} H°$ = 0.83 kcal mol^{-1} from points above T_{trs}. The single curve gives larger deviations than separate fits of the two regions, but the increases are of marginal significance.

Recent $C_p°$ data (60-298 K) for $TiO_{1.01}$ (15) are larger at all temperatures with deviations of 2-3% at 110-250 K increasing to 5% at 298 K and 7% at 60 K. The new data yield S°(298.15 K) = 8.55 cal K^{-1} mol^{-1} of TiO. We know nothing about the TiO sample (15), but it also may have been used to obtain enthalpies (700-2300 K) which are not yet published (16). Shomate (12), Naylor (13) and later Humphrey (3, see $\Delta_f H°$) all used the same sample, 99.2% pure with Si and C as impurities. The (O/Ti) ratio was ~0.994 (17). Vacancy concentration is unknown and the phase is uncertain.

Transition Data and Phase Data - See the β-crystal table for details.

Sublimation Data - *This is the difference in $\Delta_f H°$ for TiO(g) and TiO(α).*

TITANIUM OXIDE, BETA (β-TiO) CRYSTAL M_r = 63.8794

$S°(298.15\ K)$ = [38.077] J K^{-1} mol^{-1}

T_{trs} = [1265] K

T_{fus} = 2023 ± 30 K

$\Delta_f H°(298.15\ K)$ = [-538.481] kJ mol^{-1}

$\Delta_{trs}H°$ = [4.2] kJ mol^{-1}

$\Delta_{fus}H°$ = [41.8] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of α-TiO by adding $\Delta_{trs}H°$ to the difference in H°(1265 K)-H°(298.15 K) between α- and β-TiO. $\Delta_f G°$ data for β-TiO are reviewed on the table for α-TiO (9). Values of $\Delta_f H°$ derived from $\Delta_f G°$ depend on the value of S° (see Entropy). There are additional references on the $\Delta_f G°$ which deserve comment. Solid-state emf data of Hoch et al. (18) are insufficient to yield $\Delta_f G°(\beta)$, especially in the direct way used by Drowart et al. (19). Their interpretation is inconsistent with phase diagrams (20, 17) and extensive emf data (7) which show bivariant behavior in which $\Delta_f \bar{G}(O_2)$ is a strong function of (O/Ti). It is not useful to reinterpret the emf data (18); they show a temperature dependence of the wrong sign and we do not know the necessary electrode compositions. The often quoted $\Delta_f G°$ of Kubaschewski and Dench (21) is not an independent value since it assumes the correctness of the calorimetric data of the Bureau of Mines (3, 12, 13). Kubaschewski's reassessment (22, 8) of $\Delta_f \bar{G}°(O_2)$ is superseded (9) due to new data (7).

Heat Capacity and Entropy

We assume $C_p°(\beta) = C_p°(\alpha)$ as discussed on the table for α-TiO. S° is calculated in a manner analogous to that of $\Delta_f H°$. S° might be too low by as much as 3 or 4 cal K^{-1} mol^{-1} (2) due to a possible uncertainty in $\Delta_{trs}H°$ (see Transition Data). The possibility exists because experimental samples (2-4, 12, 13) were not adequately characterized as to phase and vacancy concentration.

Phase Data

Stoichiometric TiO has been identified in two crystalline forms. High-temperature β-TiO has a cubic NaCl-type structure (23), while low-temperature α-TiO has a closely related monoclinic structure (24, 25). Ideal α-TiO is an ordered array in which 1/6 of the lattice sites are vacant; half of the Ti and O atoms are missing alternately in every third (110) plane (24). β-TiO obtained at normal pressures appears to have a lower and somewhat variable (~14-15%) vacancy concentration (5), depending on conditions of preparation. Vacancy concentration can be reduced to arbitrary values (including zero) at high pressure by quenching from high temperature (8). The process is reversed on reheating at normal pressure. Vacancy concentration (6, 26) and vacancy disorder (20, 25-27) in β-TiO appear to increase with increasing temperature, but definite conclusions are hampered since most data are for samples quenched to room temperature. Hilti (25) claimed two transitions: α→cubic (vacancy superlattice)→cubic (random vacancies). Jostsons and McDougall (20) designated the β- and α-phases as γ and γ' in order to avoid confusion with other Ti-O alloys. The relatively wide homogeneity ranges of α- and β-TiO are summarized in recent phase diagrams (20, 17) and emf studies (7). Limits of stability of α-TiO and the identity of its adjacent phases are less well established (20, 17) than for β-phase. TiO is metallic, exhibiting weak paramagnetism (27) and superconductivity with T_c below 1 K (26). Ordering of the vacancies by annealing had little effect on T_c (26).

Transition Data

The nature and kinetics of α=β are crucial since we lack definite knowledge of the phases used in thermochemical studies. The transition α→β is more rapid than the reverse one. β-TiO is readily retained by quenching, but α can be obtained only by annealing (23-30) for several hours below T_{trs}. Moreover, there is disagreement as to whether the transition α→β proceeds directly (20) or via an intermediate peritectic decomposition, e.g. Ti_2O + β-TiO_{1+x} (17). Emf data (7) seem more consistent with the latter, but none of the evidence is definitive (17, 20, 24, 27-30). Lyon (5) suggested that peritectic decomposition is an alternative to direct reduction of vacancy concentration on going from α to β (see Phase Data). The difference in vacancy concentration, if real, may preclude direct equilibrium between ideal α and normal β. This could invalidate calculation of $\Delta_{trs}S$ from $\Delta_{trs}H°$ (5).

Approximate ranges for T_{trs} include 1235-1270 K from enthalpy data (13); 1235-1273 K from thermal analysis (29); between 1223 and 1263 K (20, 24), between 1223 and 1288 K (29), and between 1173 and 1223 K (28, 30), each based on the presence of α in samples quenched from various annealing temperatures. Later resistivity data (27) on Pearson's samples (28) suggest that T_{trs} is between 1233 and 1303 K. Hilti (25) reported 1253 K for the first transition and 1523 K for the second. The latter transition is not apparent in the enthalpy data (13).

We adopt T_{trs} = 1265 K and arbitrarily take $\Delta_{trs}H°$ = 1.0 kcal mol^{-1}. The apparent enthalpy difference ($\Delta_f H°$ = 0.83 kcal mol^{-1}) at T_{trs} is equal to $\Delta_{trs}H°$ only if Naylor's sample (13) was originally α-TiO and returned to α-form during drop calorimetry from above T_{trs}. Charlu et al. (2) proposed instead, based on the difference in $\Delta_c H°$ values, that $\Delta_{trs}H°$ = ~5 kcal mol^{-1} and $\Delta_{trs}S° = \Delta_{trs}H°/T_{trs}$ = ~4 cal K^{-1} mol^{-1}. The resulting increase in S°(β) would change our third-law analysis of $\Delta_r G°$ for reactions C and D (see α-TiO). It would minimize the discrepancy between $\Delta_c H°$ (3, 4) and the third-law $\Delta_f H°$ but would more than double the discrepancy (δS) in the temperature dependence of $\Delta_f G°(\beta)$ derived from Ti_2O_3 (7, 9). We prefer to minimize δS even though the larger value is compatible with the estimated uncertainty in $\Delta_f G°(\beta)$.

Entropy calculations are available for processes somewhat related to α=β. The configurational entropy of TiO(β) with random vacancies was shown to be 2.0 cal K^{-1} mol^{-1} (14). $\Delta_{fus}S°$ of 1.5 to 2.3 cal K^{-1} mol^{-1} for TiO(β, 0% vacancies) → TiO(β, 14.4% vacancies) was calculated by Lyon (5) from compressibility, thermal expansion and a PV isotherm (6). Taylor and Doyle (6) reported observing β-TiO, presumably with much reduced vacancy concentration, at 56.4 kbar and 1153 K. This yields $\Delta_T \leq$ -80° assuming the T_{trs} > 1233 K at 1 atm. We estimate ΔV = -0.16 cm^3 mol^{-1} from the densities (6, 23) observed at 25°C and combine it with ΔP to calculate $\Delta_{trs}S°$ = ~2.6 cal K^{-1} mol^{-1} for α→β. This calculation is highly uncertain; it is invalid if the transition is not an equilibrium one.

Fusion Data - See the liquid table for details.

PREVIOUS: March 1967 CURRENT: December 1973

TITANIUM OXIDE (TiO) LIQUID M_r = 63.8794

$S°(298.15\ K) = [60.140]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2023 \pm 30\ K$

$\Delta_f H°(298.15\ K) = [-493.939]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [41.8]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(TiO, ℓ, 298.15 K) is calculated from that of β-TiO by addition of $\Delta_{fus}H°$ and the enthalpy difference in enthalpy, H°(2023 K)-H°(298.15 K), between β and liquid.

Heat Capacity and Entropy

S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°$. $C_p°$ is estimated as 8 cal K^{-1} g-atom^{-1}. Below the assumed glass transition at 1200 K, $C_p°$ is taken to be the same as that of the crystal.

Fusion Data

T_{fus} was observed to be 1750°C (31), 1760 ± 25°C (32) and >1750°C (33). Incipient melting, partial melting and complete *melting were observed* (29) *at approximately 1710°, 1730° and 1760°C, respectively. We adopt 1750 ± 30°C and estimate* $\Delta_{fus}H°$ *such* that $\Delta_{fus}S°$ is 2.5 cal K^{-1} cal K^{-1}g-atom^{-1}. TiO does not melt congruently (17, 20, 29, 32, 33); there are various interpretations of the liquidus curve.

Vaporization Data

The vapor over TiO(cr, ℓ) is mainly TiO and Ti, so the residue increases in (O/Ti) ratio (34).

Enthalpy of Formation

$\Delta_f H°(298.15\ K) = 13.0 \pm 2$ kcal mol^{-1} and $D_0^0 = 158.5 \pm 2$ kcal mol^{-1} are selected from reactions A, B, C and E (16) which are summarized below. The first three are isomolecular exchange reactions studied by mass spectrometry (13, 14). Reaction E is obtained from univariant Ti_2O_3-Ti_3O_5 by combining Knudsen effusion with the pressure ratio (TiO_2/TiO) = 0.246 obtained from mass spectrometry (16). We use the same analysis (16) for (17, E), although the condensed phase may not be univariant. We presume that the smaller $D_0^0 = 145.4$ kcal mol^{-1} from reaction D is due to bias in the mass-spectrometric values (15) for the partial pressure of O(g). Larger values of D° from sublimation (17, 19) and vaporization (18) of TiO are subject to bias due to presence of species other than TiO in the vapor and to unknown liquid activities. Activities of TiO in TiO_x(cr) are very close to unity at x=1.0-1.1 and 1900 K according to emf data (20).

The analysis of Drowart et al. (14) was the key to resolution of the discrepancy in D_0^0(21); later studies (13, 16) confirmed their analysis. Our analysis uses D_0^0(GeO, g) = 156.4 ± 1.5, D_0^0(ScO, g) = 160.4 ± 2.0, and D_0^0(YO, g) = 170.4 ± 2.5 kcal mol^{-1} with other auxiliary data and newly calculated Gibbs-energy functions, all of which are essentially consistent with Drowart et al. (14, 22). Our selected D_0^0(TiO) = 158.5 ± 2 kcal mol^{-1} may be compared with 174.5 and 156.3 kcal mol^{-1} calculated by linear Birge-Sponer extrapolation of present (1) and older (23) vibrational constants of $X^3\Delta$. Kushawaha (24) used the older constants in construction of RKRV potential energy curves and thereby estimated $D_0^0 = 165.4$ kcal mol^{-1}. He also derived $D_0^0 = 167.8 \pm 20$ kcal mol^{-1} from a chemiluminescent reaction (10), but we dismiss this since auxiliary data for KO and TiCl were estimates.

G) TiO(ℓ) = TiO(g)

[b] Extreme points selected from large data set.

Heat Capacity and Entropy

Electronic levels (T_0) and vibrational-rotational constants are from Rosen (1) as supplemented (4) by extensive new data (2, 3, 5, 8, 9). Additional states near 32000 cm^{-1} (10, 3) are omitted since their effect is negligible. We estimate unknown spectroscopic constants from known values for states arising from like molecular-orbital configurations (11). Although $^3\Delta$ is the ground state (6), several authors (1-3, 12) noted that energy levels of all singlet states are approximate due to uncertainty in the low-lying $a^1\Delta$. We revise $a^1\Delta$ from 581 cm^{-1} (6) to 1000 ± 400 cm^{-1} based on the temperature dependence of band intensities (6, 7), the requirement that $b^1\Pi$ lie above $E^3\Pi$ observed at 11894 cm^{-1} in a Ne-matrix (3), and the assumption that $f^1\Delta$ (8, 4) is the perturber of $C^3\Delta$ (5). The new E and f states confirm empirical predictions (11) which suggest additional unobserved levels at ~13000 ($^3\Sigma$) and 15000 cm^{-1} $^1\Sigma$). We omit these states since their predicted energies are less well established and their contributions to $C_p°$ and S° would be quite small. The functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \Sigma_i Q_r^i Q_v^i g_i \exp(-c_2\varepsilon_i/T)$.

VANADIUM OXIDE (VO) CRYSTAL M_r = 66.9409

$S°(298.15\ K) = 39.011 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2063 \pm 10\ K$

$\Delta_f H°(0\ K) = -429.715 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -431.789 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [54.4]\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpies of formation for the vanadium oxides are based on the combustion studies by Mah and Kelley (1). The adopted value is $\Delta_f H°(VO, cr, 298.15\ K) = -103.2\ kcal\ mol^{-1}$, as reported by Mah and Kelley (1). For more details, refer to the V_2O_5(cr) table (2). We increase their stated uncertainty limits of +0.3 kcal mol^{-1} to ±1.5 kcal mol^{-1} so as to more adequately include all uncertainties in the experimental procedure, rather than just the scatter in the final results.

Other enthalpy of formation results for VO(cr) derived from combustion studies are reported as -102 kcal mol^{-1} by Samsonov (3) and -102 ± 1 kcal mol^{-1} by Vol'f and Ariya (4). However, the latter study (4) also reported a corresponding result for V_2O_5(cr) which is 5.4 kcal mol^{-1} more negative than the adopted JANAF value (2). Older work by Kobayashi (5) involving water vapor equilibrium on vanadium and its oxides and by Mixter (6) involving sodium peroxide fusions are not considered.

Heat Capacity and Entropy

Todd and Bonnickson (7) measured the heat capacity of VO(cr) in the region 55-296 K. The sample, estimated to be 98.2% pure, was prepared by heating a mixture of V(cr) and V_2O_3(cr) in a hydrogen atmosphere. The heat capacity results showed an anomaly similar to that found by Anderson (8) for V_2O_3(cr). Todd and Bonnickson (7) concluded that the ~20 cal K^{-1} mol^{-1} in excess to *that expected for a smooth $C_p°$ curve in the region 168-191 K was evidence of either an incomplete reaction in preparing* VO(cr) or subsequent disproportionation. Experimental data in this region were not reported. Using the Debye function D(398/T) as suggested by Todd and Bonnickson (7), we calculate $S°(50\ K) = 0.297$ cal K^{-1} mol^{-1} and $H°(50\ K)-H°(0\ K) = 11.051$ cal mol^{-1}. The data are graphically curve fitted assuming a smooth sequence of "data points" in the region 168-191 K. Near 298.15 K the heat capacity data of Todd and Bonnickson (7) and the derivative of the smoothed enthalpy data of Orr (9) were constrained to join smoothly. Orr (9) used the same sample as did Todd and Bonnickson (7) and measured the enthalpy (fourteen data points) in the region 394-1698 K. The heat capacities derived from the Orr (9) data were extrapolated to T_{fus} and above.

The heat capacity, entropy and enthalpy values at 298.15 K reported by Chernyaev et al. (10) for VO_x, where x = 0.86, 0.99, 1.24 and 1.30, led to values for VO(cr) which are considerably lower than our adopted values. For example, the $S°(298.15\ K)$ value derived from the data of Chernyaev et al. (10, 22) is roughly 1.3 cal K^{-1} mol^{-1} lower than our adopted value.

Phase Data

Vanadium monoxide crystallizes in the cubic NaCl-type structure and is stable over a wide range of composition, roughly between the limit $VO_{0.80}$ and $VO_{1.30}$. Details and many references may be found in Stringer (20) and Alexander and Carlson (21).

Transition Data

There exists a large volume of literature dealing with transitions in the vanadium oxide condensed phases. These various oxides show widely varying electric and magnetic properties, as is discussed by Adler (11). In the case of VO(cr), which has a wide homogeneity range, the reported data in the region of 120 K is conflicting. Sample purity, stoichiometry, and preparation undoubtedly play a major role in the appearance or lack of appearance of a possible transition. Much of the literature does not *provide adquate sample characterization for an unequivical analysis of the data.*

Conductivity measurements by Morin (12) on single crystals of VO(cr) and numerous measurements, including NMR, by Warren et al. (13) indicated a transition in the region 114-126 K and 88-125 K, respectively. The transition was described by Morin (12) as a semiconductor-metal type. This is further discussed by Zhuze et al. (14) and Hyland (15). However, Kawano et al. (16) and Takei and Koide (17) presented evidence on electric and magnetic properties and thermoelectric power for various vanadium monoxides within its homogeneity range which did not indicate any transition. Recent studies by Warren et al. (18) also indicated no evidence of a transition and, in addition, stated that the sample used in a previous study (13) was mainly V_2O_3(cr) as *determined by x-ray analysis. Many more references on this subject may be found in the compilation* by Neuberger (19) and in a review of the V-O system by Stringer (20).

We conclude that there is no transition below T_{fus} for VO(cr) based primarily on the work cited above (16-18).

Fusion Data - See the liquid table for details.

Sublimation Data

At temperatures approaching T_{fus}, VO(cr) is reported to yield a vapor containing V(g), VO(g), and VO_2(g) (2).

VANADIUM OXIDE (VO) LIQUID M_r = 66.9409

$S°(298.15\ K) = [69.137]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2063 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [-370.901]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [54.4]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(VO, ℓ, 298.15 K) is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the differences in enthalpy, H°(2063 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated as 7.5 cal K^{-1} g-atom^{-1}. Below the assumed transition temperature at 1200 K, $C_p°$ is assumed to be the same as in the crystal. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Alexander and Carlson (1) proposed a phase diagram for the V-VO system based on melting point determinations, differential thermal analysis, metallographic observations, and x-ray parametric measurements. These authors (1) reported that VO(cr) melts congruently at 2063 ± 10 K. We adopt this value for T_{fus}. In a phase diagram proposed by Stringer (2) a melting temperature of ~1998 K was suggested but the melting was not congruent.

VO(cr) has a sodium chloride structure and is stable over a wide range of composition, as is discussed, for example by Stringer (2). $\Delta_{fus}H°$ is estimated based on $\Delta_{fus}S° = 6.3$ cal K^{-1} mol^{-1} as in NaCl (3). Since VO(cr) has a defect structure, a comparison with the $\Delta_{fus}S°$ value of NaCl is not entirely satisfactory. We make this comparison, however, pending further data.

Vaporization Data

There are no data available in the literature dealing with the vaporization of VO(ℓ). We anticipate substantial decomposition to occur during heat treatment of VO(ℓ). See VO(g) table for further information (3).

Enthalpy of Formation

Based on the adopted ground state vibrational constants, a linear Birge-Sponer extrapolation yields a dissociation energy of D_0^o = 6.039 eV (139.3 kcal mol^{-1}) for VO(g). Applying a correction for the ionicity in the V-O bond (1), we recalculate D_0^o = 6.495 eV (149.8 kcal mol^{-1}). This latter value leads to a $\Delta_f H°(298.15\ K)$ value of 31.6 kcal mol^{-1} using auxiliary data (2).

Berkowitz et al. (3) determined the composition and partial pressures of the vapor over VO(cr) by employing a mass spectrometer to analyze the vapors effusing from a tungsten Knudsen cell containing VO(cr). The vapors detected mass spectrometrically at 1945 K were reported to be V(g), VO(g), and VO_2(g). The VO^+ intensity was determined in two sets of experiments using the temperature variation method. Berkowitz et al. (3) analyzed these results using 2nd law methods and reported $\Delta_r H°(T)$ = 125.2 kcal mol^{-1} (1690-1945 K) and 124.6 kcal mol^{-1} (1680-1950 K) for the reaction VO(cr) = VO(g). Assigning these enthalpies of reaction to an intermediate temperature of 1800 K, we calculate $\Delta_f H°$(VO, g, 298.15 K) = 30.1 and 30.4 kcal mol^{-1}, respectively, using auxiliary data (2). Berkowitz et al. (3) also used the absolute pressure method and determined the partial pressure of VO(g) at two temperatures, 1875 K and 1876 K. The two absolute pressure data points differ in value by ~25%. A 3rd law analysis of these two data points leads to $\Delta_f H°$(VO, g, 298.15 K) of 23.6 and 24.7 kcal mol^{-1}. We prefer the 2nd law results of Berkowtiz et al. (3) since each result is based on multiple data points (~6) which cover a 260 K range.

Coppens et al. (4) used a combination of mass spectrometric and Knudsen cell techniques to determine the partial pressures necessary to define the equilibrium in the system VO(g) + Ge(g) = GeO(g) + V(g). The authors analyzed eight data points (1927-2145 K) by the 3rd law method and reported $\Delta_r H°(0\ K)$ = 7.60 ± 0.38 kcal mol^{-1} which actually applies to the reverse reaction (14). The Gibbs energy functions used by Coppens et al. (4) for VO are very similar to those adopted here. Using auxiliary data (2, 5), we calculate $\Delta_f H°(298.15\ K)$ = 29.1 kcal mol^{-1} for VO(g).

An effusion-mass spectrometric investigation of the vapors in equilibrium with V_2O_3(cr) was conducted by Farber et al. (6). Their study, using an aluminum cell, showed that the vapors at 2270 K contained V(g), VO(g), and VO_2(g) as well as Al(g), AlO(g), and Al_2O(g). A 3rd law analysis of the data at 2270 K yields $\Delta_r H°(298.15\ K)$ = -26.5 kcal mol^{-1} for the reaction AlO(g) + V(g) = VO(g) + Al(g). Using auxiliary data (2) we calculate $\Delta_f H°(298.15\ K)$ = 38.7 kcal mol^{-1} for VO(g). Farber et al. (6), however, reported the use of a more recent determination of $\Delta_f H°(298.15\ K)$ for AlO(g) (7). If this latter value (+16.57 kcal mol^{-1}) is used, then the $\Delta_f H°(298.15\ K)$ value for VO(g) is 35.3 kcal mol^{-1}.

Frantseva and Semenov (8) studied the evaporation of V_2O_3(cr) by a mass spectrometer used in conjunction with a double effusion chamber. They reported a D_0^o value for VO(g) which is dependent, however, on their D_0^o value for VO_2(g) (2). The mass spectrometric study by Shchukarev et al. (9) detected VO(g) above V_2O_4(cr) and V_2O_3(cr) but there was insufficient data reported to permit the calculation of a $\Delta_f H°(298.15\ K)$ value for VO(g).

We adopt $\Delta_f H°(298.15\ K)$ = 30.5 kcal mol^{-1} for VO(g). This value is a rounded average of the two 2nd law treatments from Berkowitz et al. (3) and the results from Coppens et al. (4). Each of these three sets of experiments involve multiple data points. Most of the remaining studies each involved only one data point. However, it should be noted that the $\Delta_f H°(298.15\ K)$ derived from the Hildenbrand correction to the linear Birge-Sponer extrapolation is within 1.1 kcal mol^{-1} of the adopted value. The adopted enthalpy of formation leads to a dissociation energy of D_0^o = 150.9 kcal mol^{-1} or 6.542 eV.

Heat Capacity and Entropy

Much of the spectroscopic work involving VO(g) has been reviewed and referenced by Rosen (10) and Weltner (11). The adopted vibrational and rotational constants as well as the electronic levels are those tabulated by Rosen (10). The EPR work of Kasai (12) and the optical absorption study by Richards and Barrow (13) established that the ground state was $^4\Sigma^-$. As reported in Rosen (10) there is evidence from matrix studies indicating a transition at 23890 cm^{-1}. We assume this level has a quantum weight of 4. the full weight of 8 is assigned to be B $^4\Pi$ state, rather than estimating the splitting. The Gibbs energy functions used here are approximately 3 cal K^{-1} mol^{-1} less than those proposed by Brewer and Rosenblatt (14). The difference arises from the fact that Brewer and Rosenblatt approximated the VO electronic levels by using V^{++} electronic levels (which include many low lying levels) whereas we have used the observed VO electronic levels.

	[19189]	[6]

ω_e = 1065 cm^{-1} $\omega_e x_e$ = [3.85] cm^{-1} σ = 1
B_e = [0.3498] cm^{-1} α_e = [0.0016] cm^{-1} r_e = [1.81] Å

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(WO, g, 298.15\ K)$ = 101.6 kcal mol^{-1}, is derived from the enthalpy of reaction, $\Delta_r H°(298.15\ K)$ = −42.0 kcal mol^{-1} for WO(g) + W(cr) + O(g) with all JANAF auxiliary data. The value of $\Delta_r H°(298.15\ K)$ was calculated by the 3rd law method from the partial pressure data which were determined mass-spectrometrically in the temperature range from 2188 to 2475 K by DeMaria et al. (1). The drift in the 3rd law analysis was −20 ± 7 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

The fundamental vibrational frequency, the ground state configuration, and the probable electronic levels for tungsten monoxide (g) were obtained from the infrared and ultraviolet spectroscopic investigations by matrix isolation by Weltner and McLeod (2). The rotational constant B_e was calculated from the estimated bond distance of WO(g). The value x_e was calculated from the relation $x_e u^{1/2}$ = 0.014 which was given by Barrow and Caunt (3). The constant (0.014) was estimated based on ZrO(g) and VO(g). The value of α_e was calculated from the Morse potential function.

$\omega_e = 978\ cm^{-1}$ $\omega_e x_e = 4\ cm^{-1}$ $\sigma = 1$
$B_e = 0.4142\ cm^{-1}$ $\alpha_e = 0.0023\ cm^{-1}$ $r_e = 1.711$ Å

Enthalpy of Formation

$\Delta_f H°(298.15\ K) = 14.0 \pm 12\ kcal\ mol^{-1}$ is calculated from $\Delta_r H°(298.15\ K) = 290.342 \pm 12.8\ kcal\ mol^{-1}$ for the reaction Zr(cr) + ZrO_2(cr) = 2 ZrO(g). The value of $\Delta_r H°(298.15\ K)$ is obtained by the 3rd law analysis from the mass spectrometric studies of Chupka et al. (1). They observed the variation of the ZrO^+ ion intensity over the system Zr + ZrO_2 and reported equilibrium constants for the reaction Zr + ZrO_2 = 2 ZrO in the range 2124-2322 K. The 3rd law drift is $-58 \pm 28\ cal\ K^{-1}\ mol^{-1}$.

Heat Capacity and Entropy

The ground state of ZrO(g) was assumed to be $^1\Sigma^+$ as determined from the matrix isolation spectra of Weltner et al. (2). Previously this had been described as the lower state in the A band system reported by Uhler and Akerlind (3).

All molecular constants were obtained from Uhler and Akerlind (3) except $\omega_e = 978\ cm^{-1}$ and $\omega_e x_e = 4\ cm^{-1}$ which were calculated from ω and $\alpha_e = 0.0023\ cm^{-1}$ using the equations

$$\alpha_e = \frac{6\,(\omega_e x_e \cdot B_e^3)^{1/2}}{\omega_e} - \frac{6\,B_e^2}{\omega_e} \quad \text{and} \quad \omega = \omega_e - 2\,\omega_e x_e = 969.76\ cm^{-1}$$

The higher electronic levels were obtained or estimated from the correlation diagram given by Weltner and McLeon (2).

Enthalpy of Formation

Zero by Definition.

Heat Capacity and Entropy

The thermal functions are calculated using the program of McBride and Gordon (1). The contributions of vibrational anharmonicity, rotation-vibration interaction, and centrifugal stretching are calculated via the procedures given by Pennington and Kobe (3). In this procedure the energy levels are calculated as follows: $\varepsilon = T_o + G(v) - G(o) + B_v J(J+1) - D_v J^2(J+1)^2$ where $G(v) = \omega_e(v+1/2) - \omega_e x_e(v+1/2)^2 + \omega_e y_e (v+1/2)^3 + \omega_e y_e (v+1/2)^4$ and $B_v = B_e - \alpha_1(v+1/2) + \alpha_2(v+1/2)^2 + \alpha_3(v+1/2)^3$ and $D_v = D_e + \beta_i(v+1/2)$. Where a value of D_e is not available it is calculated to be $D_e = 4B_e^3/\omega_e^2$.

Molecular constant data in the table above is from Krupenie (2) with the exception of B_e and α_i for the $C\ ^3\Delta_{ui}$ state which we have estimated by analogy with neighboring states of the same electron configuration. Electronic levels above 50,000 cm^{-1} given by Krupenie are not included since they make negligible contributions to the thermodynamic properties at 6000 K.

The value of S°(298.15 K) agrees exactly with the CODATA recommended value (4). It also agrees with the values of McBride et al. (5) and Gurvich et al. (6) within the stated uncertainty. The uncertainty in S°(298.15 K) is due to uncertainties in fundamental constants (particularly the gas constant), the atomic weight, and the ground state molecular constants. At high temperatures, further uncertainties arise from excited state molecular constants and approximate procedures used to account for higher vibrational-rotational levels of all states. Despite these increased uncertainties, our values of S° are within 0.016 (6000 K) and 0.035 (5000 K) cal $K^{-1}\ mol^{-1}$ of those calculated by superior methods (5, 6) using older molecular constants.

Enthalpy of Formation

The adopted value for the enthalpy of formation of $O_2^+(g)$, $\Delta_f H°(0\ K) = 278.37 \pm 0.2\ kcal\ mol^{-1}$ is that recommended in a critical review on the energetics of gaseous ions by Rosenstock et al. (1). This value is derived from ionization potentials determined in the photoelectron spectrum of O_2 by Edqvist et al. (2), the IP values are 12.071 ± 0.005 ev for the $X^2\Pi_{3/2g}$ state and 12.095 ± 0.005 ev for the $X^2\Pi_{1/2g}$ state.

$\Delta_f H°(O_2^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(O_2, g, 0\ K)$ by using $IP(O_2)$ with JANAF enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $O_2(g)$, $O_2^+(g)$, and $e^-(g)$. $\Delta_f H°(O_2 \rightarrow O_2^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (1). $\Delta_f H°(298.15\ K)$ should be changed by $-6.197\ kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The electronic and molecular constants are from the critical review of Krupenie (3). Electronic levels above 50000 cm^{-1} given by Krupenie are not included since they make negligible contributions to the thermodynamic properties at 6000 K. The thermodynamic functions are calculated using first-order anharmonic corrections to Q_r^1 and Q_v^1 in the partition function $Q = Q_{tr}Q_r^1Q_v^1g_1\exp(-c_2\varepsilon_i/T)$ Use of the program of McBride and Gordon (4) yields the same results.

The ground state is taken to be $^2\Pi_{3/2g}$ with a separation of the ground state doublet levels of ~200 cm^{-1}. The hypothetical $^2\Pi$ state without spin-orbit splitting would be 100 cm^{-1} higher (3). Such a shift of the electronic energy levels does not significantly alter the thermal functions. The main source of error in the S°(298.15 K) value lies in the neglect of a more exact treatment of the splitting of the $X^2\Pi$ ground state.

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^2\Pi_g$	0	4

$\omega_e = 1089 \pm 40\ cm^{-1}$ $\omega_e x_e = 12.1 \pm 1.6\ cm^{-1}$ $\sigma = 2$
$B_e = 1.17 \pm 0.02\ cm^{-1}$ $\alpha_e = [0.017]\ cm^{-1}$ $r_e = 1.341 \pm 0.010$ Å

Enthalpy of Formation

The enthalpy of formation at 0 K for $O_2^-(g)$ is based n the electron affinity value derived from a thorough analysis of the laser photodetachment measurements of Celotta et al. (1). This study let to $EA(O_2) = 0.440 \pm 0.008$ eV. Using auxiliary data (2), we calculate $\Delta_f H°(O_2^-, g, 0\ K) = 10.15 \pm 0.18$ kcal mol^{-1} and $D_0^0(O_2^-) = 94.4 \pm 0.3$ kcal mol^{-1}; the latter value assumes dissociation into ground state O(g) and $O^-(g)$. The adopted $EA(O_2)$ value is also recommended by Rosenstock et al. (3) and Massey (4). Both of these latter studies have reviewed and summarized earlier work from which EA values could be derived.

$\Delta_f H°(O_2^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(O_2, g, 0\ K)$ by using $EA(O_2)$ with JANAF (2) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $O_2^-(g)$, $O_2(g)$, and $e^-(g)$. $\Delta_r H°(O_2^- \rightarrow O_2 + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The laser photodetachment study of Celotta et al. (1) which yielded a precise value for $EA(O_2)$ also yielded precise values for r_e and B_e as well as values for ω_e and $\omega_e x_e$. We adopt these values and calculate α_e assuming a Morse function for the ground state. Support for these values comes from recent studies based on total scattering cross section (5) and differential eleastic cross section (6, 7). Other (earlier) studies yielding vibrational information are discussed by Krupenie (8). The recent ab initio study by Das et al. (11) suggests slightly different vibrational-rotational constants (ω_e = 1098, $\omega_e x_e$ = 9.04, B_e = 1.135, and α_e = 0.0151 cm^{-1}).

The ground and excited electronic states are discussed by Krupenie (8), Massey (4), and Das et al. (11). The approximate theoretical potential energy diagram given by Krupenie (8) suggests a $^2\Pi_g$ ground state with three rather low lying excited states: $^4\Sigma_u^-$ at ~21000 cm^{-1}, $^2\Pi_u$ at ~28500 cm^{-1}, and $^2\Sigma_u^-$ at ~32300 cm^{-1}. The ab initio study by Das et al. (11) suggests the same ordering of the levels at 19833 cm^{-1}, 27213 cm^{-1}, and 30076 cm^{-1}. The fluorescence observed by Rolfe (9) was assigned as $^2\Pi_{ui} \rightarrow X^2\Pi_{gi}$, but an upper state assignment of $^2\Sigma_u^-$ cannot be ruled out (8). This study indicated that the presumed $^2\Pi_{ui}$ state lies at 29400 cm^{-1} (which we adopt), in good agreement with the calculated potential energy diagram. Hurst and Bortner (10) obtained evidence of excitation to an electronic state of O_2^- (presumable $^4\Sigma_u^-$) which lies approximately 1 eV above the ground state. The potential energy diagrams given by Krupenie (8) and Das et al. (11) suggest this level is significantly higher. The position of this level will not significantly affect the entropy values.

The three excited states are predicted to be quite shallow (binding energies ~ 1 eV) as compared to the ground state. The inclusion in our calcualtion of such states, with the use of appropriate vibrational-rotational constants as given by Das et al. (11) would lead to erroneous heat capacity values above 3000 K. The proper inclusion of these three excited states would require a direct summation technique with rotational cutoff.

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is calculated from an estimated enthalpy of dissociation (270 ± 25 kcal mol^{-1}) reported by Brewer and Rosenblatt (1)

Heat Capacity and Entropy

The molecular constants selected for this table were estimated by Gordon (2). The molecular constants for PO_2(g) have been estimated by Gordon (2), Potter et al. (3) and Henderson and Scheffee (4). The entropies at 3000 K calculated from these three estimates differ by less than 0.8 cal K^{-1} mol^{-1}. The principal moments of inertia are: I_A = [0.8775 x 10^{-39}], I_B = [9.9337 x 10^{-39}], and I_C = [10.8112 x 10^{-39}] g^3 cm^6

PREVIOUS: September 1962 (1 atm) CURRENT: September 1962 (1 bar)

$S°(298.15\ K) = 71.797 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -269.874 \pm 2.9\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -274.470 \pm 2.9\ kJ\ mol^{-1}$

Enthalpy of Formation

Espada et al. (1) have calorimetrically determined the heat of the reaction $PbO_2(cr) + 2\ H_2(g) \rightarrow Pb(cr) + 2\ H_2O(\ell)$ as -71.02 ± 0.16 kcal mol^{-1} from which they derive $\Delta_f H°(PbO_2, cr, 298.15\ K) = -65.61 \pm 0.32$ kcal mol^{-1}. This value assumes that the PbO_2 was 100% pure, in fact it is virtually impossible (2) to prepare a sample free of water and fully oxidized. Thus, Espada et al. (1) have increased their uncertainty to ±0.7 kcal mol^{-1} to cover the likely spread of values assuming typical compositions.

Millar (3) has recalculated the data of Glasstone for the Gibbs energy of the cell reaction $PbO_2(cr) + H_2(g) \rightarrow PbO(red) + H_2O(\ell)$ as $\Delta_f G°(298.15\ K) = -49.600$ kcal mol^{-1}. With auxiliary Gibbs energy data (4, 5) we calculate $\Delta_f G°(PbO_2, cr, 298.15\ K) = -52.33$ kcal mol^{-1} which corresponds to $\Delta_f H°(PbO_2, cr, 298.15\ K) = -66.45$ kcal mol^{-1} in reasonable agreement with the value reported by Espada et al. (1).

We adopt the value $\Delta_f H°(PbO_2, cr, 298.15\ K) = -65.6 \pm 0.7$ kcal mol^{-1}.

Heat Capacity and Entropy

Duisman and Giauque (2) have reported the heat capacity of PbO_2 from 15 to 318 K and have calculated the entropy at 298.15 K based on $S°(15\ K) = 0.079$ cal $K^{-1}\ mol^{-1}$. They had considerable difficulty in preparing a suitable sample of PbO and finally used a sample containing PbO and H_2O, as impurities, for which significant corrections were made to the measured data. Millar (3) also has measured the heat capacity from 70 to 298 K but is 7% higher than the adopted values.

High temperature enthalpy data have been reported by Palmaer (6) and Bousquet et al. (7) but these data suffer from unknown amounts of impurity, for which the correction is probably substantial, and decomposition to intermediate oxides. Thus, the heat capacity above room temperature was estimated by a graphical extrapolation of the low temperature heat capacity.

Decomposition Data

Numerous investigators have reported the decomposition of PbO_2 at elevated temperatures, however, the exact processes are still not well defined. Otto (8) indicates a three step process to Pb_3O_4, but the intermediate compositions are not established. The temperature at which the decomposition pressure of oxygen reaches 0.2 atm was reported as 260°C by Otto while White and Roy (9) indicate 293°C. The enthalpies and entropies reported are in serious disagreement with adopted values and indicate failure to attain equilibrium.

1361.76(1)

ground state g.w. = 1

Point Group: C_{2v} $\sigma = 2$
Bond Distance: S-O = 1.432 ± 0.003 Å
Bond Angle: O-S-O = 119.53 ± 0.40
Product of the Moments of Inertia: $I_A I_B I_C = 1.070 \times 10^{-115}\ g^3\ cm^6$

Enthalpy of Formation

Eckman and Rossini (1) measured the enthalpy of combustion of rhombic sulfur to SO_2. Changes due to different atomic weights and electrical constants, though negligible, have been made.

Heat Capacity and Entropy

The functions were calculated by Gordon (2) using the method of Pennington and Kobe (3). Structural parameters are given by Sirvetz (4), obtained from microwave measurements. Frequencies were measured by Shelton et al. (5). A 3rd law value of S°(298.15 K) = 59.24 cal K^{-1} mol^{-1} was obtained by Giauque and Stevenson (6). The principal moments of inertia are (all in g cm^2): $I_A = 1.380 \times 10^{-39}$, $I_B = 8.131 \times 10^{-39}$, and $I_C = 9.534 \times 10^{-39}$.

PREVIOUS: June 1961 (1 atm) CURRENT: June 1961 (1 bar)

$S°(298.15\ K) = 50.053\ J\ K^{-1}\ mol^{-1}$

$T_{trs1} = 543 \pm 3$ K(low cristobalite → high cristobalite)

$T_{trs2} = 1079 \pm 250$ K(high quartz → high cristobalite)

$T_{fus} = 1996 \pm 5$ K(high cristobalite → liquid)

$\Delta_f H°(298.15\ K) = -905.489\ kJ\ mol^{-1}$

$\Delta_{trs1} H° = 1.343 \pm 0.25\ kJ\ mol^{-1}$

$\Delta_{trs2} H° = 2.008 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 9.581 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of low cristobalite by addition of $\Delta_{trs}H° = 0.321\ kcal\ mol^{-1}$ and the difference between H°(543 K)-H°(298.15 K) for low and high forms.

Heat Capacity and Entropy

$C_p°$ is derived from enthalpies of Mosesman (1) and White (2) whose data deviate from the adopted functions by -0.6 to +0.5% and +0.9 to 0.0%, respectively. White's deviations for cristobalite have a magnitude and trend similar to his deviations for quartz and vitreous silica. Data of Wietzel (3) for his sample prepared at 1600°C deviate by +3% at 673 K and +1.6% at 1973 K. $C_p°$ below 543 K is smoothly extrapolated to give the proper trend in the Gibbs energy, but the heat capacity at 298 K is not realistic. The entropy is calculated in a manner analogous to that of the enthalpy of formation.

Transition Data

Literature on the polymorphism of SiO_2 is voluminous but is summarized in detail in recent books by Sosman (4) and Eitel (5). The known phases of SiO_2 include quartz, tridymite(?), cristobalite, vitreous silica and the more recently discovered high pressures phases. Muan (6) concisely reviewed the still controversial question of whether tridymite is stabilized only by the presence of foreign ions or whether it is a stable phase of SiO_2 intermediate between quartz and cristobalite. Transitions among the different phases are generally sluggish because of large energy barriers to the structural change and small differences in Gibbs free energies. As a result, the phases often persist far into metastable regions. In contrast, transitions within a particular phase are rapid and reversible (i.e., the low → high inversions of quartz or cristobalite).

High cristobalite is the stable phase near T_{fus}. It becomes metastable with respect to quartz at lower temperatures but persists down to the high → low inversion at 543 K (see table for low cristobalite). The high form is cubic and the low form tetragonal (12, 13).

The adopted tables give 1079 ± 250 K as the temperature at which $\Delta_r G° = 0$ for high quartz → high cristobalite; $\Delta_{trs}H° = 0.48 \pm 0.15\ kcal\ mol^{-1}$ is the corresponding enthalpy difference. The uncertainty in T_{trs} is derived from that in $\Delta_{trs}H°$ which, in turn, is taken from $\Delta_r H°(970\ K) = 0.45 \pm 0.15\ kcal\ mol^{-1}$ obtained by Holm (7) from $\Delta_{sol}H°$ measurements in an oxide melt. It is apparent that T_{trs} is extremely sensitive to small changes in G or H. Holmquist (8) tentatively placed this inversion at 1298 ± 25 K but did observe cristobalite formation at temperatures as low as 1171 K.

Fusion Data

Melting point data were reviewed by Schneider (9) and adjusted to the 1948 International Temperature Scale. The adopted melting point for cristobalite is based on Greig (10). $\Delta_{fus}H°$ is calculated as the difference in $\Delta_f H°$ for liquid and crystal at T_{fus}. Mackenzie et al. (11) showed that cristobalite may be superheated by as much as 40° above T_{fus} due to its slow rate of fusion.

PREVIOUS: CURRENT: June 1987

$S°(298.15\ K) = 43.396 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 543 \pm 3$ K (low cristobalite → high cristobalite)

$\Delta_f H°(0\ K) = -903.482 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -908.346 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 1.343 \pm 0.25\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of quartz using $\Delta_r H°(970\ K) = 0.45 \pm 0.15$ kcal mol^{-1} for high quartz → high cristobalite, as determined by Holm (1) from $\Delta_{sol}H°$ is an oxide melt. This value reduces to $\Delta_r H°(298.15\ K) = 0.60$ kcal mol^{-1} for low quartz → low cristobalite. Kracek (2) obtained essentially the same value, $\Delta_r H°(298.15\ K) = 0.63$ kcal mol^{-1}, from $\Delta_{sol}H°$ in HF(aq, 74.7°C), while Hummel (3) found $\Delta_r H°(298.15\ K) = 1.80$ kcal mol^{-1} from $\Delta_{sol}H°$ in HF(aq, 26.5°C). The larger $\Delta_r H°$ corresponds to a less negative $\Delta_f H°$ (i.e., less stable) and suggests that the sample of Hummel has disorder approaching that of vitreous silica. Presumably, this disagreement arises from different methods of preparation of cristobalite from quartz. Holm heated for 24 hours at 1743 K, while Hummel heated for 4 hours at 1973 K. Hummel's sample was then ground and treated with dilute HF to remove amorphous surface layers created by grinding; particles smaller than 2.5 microns were used in order to obtain adequate rates of dissolution. Neither author gave X-ray or DTA evidence to confirm that the samples were the more stable, ordered form of cristobalite (15).

The calorimetric data are summarized below along with equilibrium data which confirm the adopted values of $\Delta_f H°$ for cristobalite and quartz. Data from Matoba (5) and Rein (6) were reduced to the standard state of Si(ℓ) using activity coefficients from the curves of (10).

*Values at T are from 2nd law analysis while those at 298.15 K are from 3rd law.

Reactions:
A) SiO_2(quartz, low or high) = SiO_2(cristobalite, low or high)
B) SiO_2(high cristobalite) + 2 H_2(g) = Si(ℓ) + 2 H_2O(g)
C) SiO_2(high cristobalite) + 2 C(graph) = Si(ℓ) + 2 CO(g)
D) SiO_2(high cristobalite) + 2 SiC(β) = 3 Si(ℓ) + 2 CO(g)
E) SiO_2(high cristobalite) + 3 C(graph) = SiC(β) + 2 CO(g)

Heat Capacity and Entropy

$C_p°$ below 300 K is based on data of Westrum (11). Earlier data of Anderson (12) are in satisfactory agreement. The entropy is obtained from $C°_p$ using $S°(5\ K) = 0.0007$ cal K^{-1} mol^{-1}. $C°_p$ above 300 K is derived from enthalpy data of Mosesman (13) and White (14). The former deviate from the adopted functions by -0.7 to 0.5% and the latter by +0.4%. Although the functions above 300 K appear to be reliable, it would be desirable to have new data for a well-characterized sample (see Transition Data).

Transition Data

Low cristobalite is metastable with respect to quartz but persists up to T_{trs}. T_{trs} is taken as the temperature at the peak in the heating curve for well-ordered cristobalite; however, see (15, 16) for detaled discussions of temperatures about 25 lower which were found from cooling curves. $\Delta_{trs}H°$ is derived from enthalpy data (13, 14) for high cristobalite using the adopted enthalpy for the low form. The enthalpy data of Mosesman (13) gave a lower T_{trs} which suggests that the sample was less well-ordered than desirable. $\Delta_{trs}H°$ is confirmed, however, by other data which are summarized below. Additional polymorphism is discussed on the table for high cristobalite.

PREVIOUS: CURRENT: June 1967

$S°(298.15\ K) = 41.463 \pm 0.13\ J\ K^{-1}\ mol^{-1}$

$T_{trs1} = 847 \pm 1.5\ K$ (low quartz → high quartz)

$T_{trs2} = 1079 \pm 250\ K$ (high quartz → high cristobalite)

$T_{fus} = 1696 \pm 50\ K$ (high quartz → liquid)

$\Delta_f H°(0\ K) = -905.872 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -910.857 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{trs1} H° = 0.728 \pm 0.17\ kJ\ mol^{-1}$

$\Delta_{trs2} H° = 2.008 \pm 0.63\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 7.699 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is based on data of Wise (1) for combustion of SiO_2(low quartz) and Si(cr) in F_2 to form SiF_4(g). Good (2) burned a mixture of Si(cr) and vinylidene fluoride polymer in oxygen in the presence of HF(aq) to form H_2SiF_6(aq, HF). Combining this result with a previous heat of solution of quartz (3), the authors derived $\Delta_f H°(298.15\ K) = -217.5 \pm 0.5$ kcal mol^{-1}. Agreement with the adopted value is excellent, considering the complexity of the latter scheme. Both schemes are independent of $\Delta_f H°$(HF), although the polymer-Si scheme depends on the heat of dilution of HF(aq). Wise (1) has reviewed other data which confirm the adopted value rather than the oxygen combustion value (4) of -209.9 kcal mol^{-1}. Pertinent equilibrium data are analyzed on the table of SiO_2(low cristobalite), while the calorimetric results are summarized below.

Source	Reaction	$\Delta_r H°(298.15\ K)$, kcal mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}
(1)	SiO_2(low quartz) + 2 F_2(g) → SiF_4(g) + O_2(g)	-168.26 ± 0.28	-217.72 ± 0.34
(2)	See text.	--	-217.5 ± 0.5
(3)	Si(cr) + 2 O_2(g) → SiO_2(low quartz)	-209.9	-209.9

Heat Capacity and Entropy

Heat capacities below 300 K are based on data of Jones (5) and Westrum (6). Earlier data of Anderson (7) are in good agreement. The entropy is obtained from $C_p°$ using $S°(2\ K) = 0.00001$ cal K^{-1} mol^{-1} from 300 to 847 K is derived from adiabatic calorimetric data of Moser (8) and Sinel'nikov (9). The adopted $C_p°$ is discontinuous at 847 K and $\Delta C_p° = -2.17$ cal K mol . Values above the transition temperature are based on data of Moser and on data up to 1473 K obtained with a thermal analysis method by Leonidov (10). $C_p°$ is extrapolated linearly to higher temperatures.

From a review of data available before 1953, Kelley (11) selected almost identical enthalpies below 847 K but a value higher by 96 cal K^{-1} mol^{-1} at 900 K. The higher value, due to use of a larger $\Delta_{trs1} H°$, was presumably based on Roth (12), Wietzel (13) and White (14) whose enthalpy data were given the most weight by Kelley. Near 900 K these three sets of data deviate from the adopted function by -150±30, +130±40 and +15±35 kcal mol^{-1}, respectively; however, a recent enthalpy datum (15) obtained by transposed temperature drop calorimetry deviates +75 cal K^{-1} mol^{-1} at 968 K.

Transition Data

$T_{trs1} = 847 \pm 1.5$ K is based on thermal analysis of many specimens by Keith and Tuttle (16). Wide variations in T_{trs1} for some specimens were attributed by the authors to small amounts of impurities. The discontinuity in the volume curve (17) during inversion from trigonal low quartz to hexagonal high quartz suggests that the transition should be treated as first order. Thus, the enthalpy of transition is derived as (1011-854+17) = 174 cal K^{-1} mol^{-1}, where 1011 ± 6 is H°(873.15 K) - H°(823.15 K) measured by Moser (8), 854 is the corresponding increment calculated from the JANAF $C_p°$ and 17 is an endpoint correction for the difference between the observed and adopted curves below 823.15 K. Some recent data which confirm the adopted $\Delta_{trs1} H°$ are summarized below.

Source	Method	$\Delta_{trs1} H°$, kcal mol^{-1}
(8)	H and $C_p°$ from adiabatic calorimetry	0.174
(9)	Integration of $C_p°$ from adiabatic calorimetry	0.143
(10)	Thermal analysis	0.198
(17)	ΔV with dT/dP = 0.026 K/atm	0.12
(18)	Microcalorimetric thermal analysis, Single crystal	0.156, 0.165, 0.178 ± -.010
	Various crushed samples	0.124 to 0.193

Additional polymorphism of SiO_2 is discussed on the table for high cristobalite. Quartz has been superheated through the cristobalite region to some 300 above its metastable melting point. This melting point is calculated from the adopted tables as 1696 ± 50 K, which agrees well with the range 1673 - 1723 K indicated by the data of Mackenzie (19). The adopted tables predict the inversion of high quartz to high cristobalite at 1079 ± 250 K. Holmquist (20) tentatively placed this inversion at 1298 ± 25 K. $\Delta_{trs2} H°$ and $\Delta_{fus} H°$ are calculated from the differences in the $\Delta_f H°$ values of the appropriate phases at T_{trs2} and T_{fus}.

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

SILICON OXIDE (SiO_2) LIQUID M_r = 64.0843

$S°(298.15\ K) = 47.928 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1996 \pm 5$ K(high cristobalite + liquid)

$\Delta_f H°(0\ K) = 897.756\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -902.661\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 9.581 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell$, supercooled, 298.15 K) is calculated from that of quartz using $\Delta_r H°(970\ K) = 1.45 \pm 0.15$ kcal mol^{-1} for high quartz + $SiO_2(\ell)$, as determined by Holm (1) from $\Delta_{sol} H°$ in an oxide melt. This value reduces to $\Delta_r H°(298.15\ K) = 1.96$ kcal mol^{-1} for low quartz + $SiO_2(\ell)$ and is consistent within ±0.3 kcal mol^{-1} with other calorimetric data summarized below. Earlier results were reviewed by Hummel (4).

Source	Method	Reaction	T/K	$\Delta_r H°(T)$ kcal mol^{-1}	$\Delta_r H°(298.15\ K)$ kcal mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

A. SiO_2(quartz, low or high) + $SiO_2(\ell)$

B. $SiO_2(\ell) + 2\ F_2(g) + SiF_4(g) + O_2(g)$

Heat Capacity and Entropy

$C_p°$ below 300 K is based on data of Flubacher (5) and Westrum (6) for samples annealed at 1100 and 1070°C, respectively. Data of Turdakin (7) are higher by about 1% in the range 60-160 K and at 300 K but are in agreement elsewhere. The entropy is calculated from $C_p°$ using $S°(2.34\ K) - S°(0\ K) = 0.0001$ cal $K^{-1} mol^{-1}$ and $S°(0\ K) = 1.098$ cal $K^{-1}\ mol^{-1}$. $C_p°$ data (6) for a different sample annealed at 1300°C yield an entropy larger by <0.04 cal $K^{-1}\ mol^{-1}$. Earlier data were reviewed by Kelley (8). The residual entropy is calculated from $S°(0\ K) = S°(1996\ K) - S°(1996;0\ K) = 41.258 - 40.160 = 1.098$ cal $K^{-1}\ mol^{-1}$, where 40.160 is obtained from the adopted functions, while 41.258 is the sum of $\Delta_{fus} S° = 1.14$ cal $K^{-1}\ mol^{-1}$ and $S°(1996\ K) = 40.111$ cal $K^{-1}\ mol^{-1}$ for high cristobalite. We estimate the uncertainty as ±0.3 cal $K^{-1}\ mol^{-1}$, primarily from the uncertainty in $\Delta_{fus} H°$.

$C_p°$ above 300 K is based on adiabatic calorimetric data of Moser (9) up to 900 K. Enthalpy data of White (10) and Fischer (11) are in excellent agreement. $C_p°$ from 900 to 1500 K is derived from enthalpy data of Southard (12) and White (10). Maximum deviation of the data from the adopted values in this range is 0.5%. Enthalpy data of Egan (13) and Kelley (14) deviate from the adopted values by less than 1% in the range 1000-1500 K, although large positive deviations appear at lower temperatures.

In the region 1500-1700 K, the adopted $C_p°$ shows a rapid, sigmoidal rise which is suggested by the enthalpy data of Wietzel (15). This is presumed to be the glass transition region in which $C_p°$ rises to that of the stable liquid. $C_p°$ above 1700 K is estimated as 20.5 cal $K^{-1}\ mol^{-1}$ or 6.83 cal K^{-1} g-atom^{-1}. This value is consistent with the enthalpy data (15) and with liquid heat capacities of Al_2O_3, $Na_2Si_2O_5$, and Na_2SiO_3.

Fusion Data

The melting point of high cristobalite is 1996 ± 5 K, while the metastable melting point of high quartz is 1696 ± 50 K. $\Delta_{fus} H°$ is the difference between $\Delta_f H°$ for liquid and high cristobalite at T_{fus}. Values ranging from 1.8 to 3.6 kcal mol^{-1} have been derived from various interpretations of phase diagrams (1).

SILICON OXIDE (SiO_2) IDEAL GAS M_r = 60.0843

$S°(298.15\ K) = [228.976]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -304.11 \pm 33.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -305.43 \pm 33.5\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
[980] (1)
[370] (2)
[1430](1)

Ground State Quantum Weight: [1] σ = [2]

Point Group: [$D_{\infty h}$]

Bond Angle: O-Si-O = [180]°

Bond Distance: Si-O = [1.55] Å

Rotational Constant: B_0 = [0.219280] cm^{-1}

Enthalpy of Formation

The adopted value is based on the data summarized below. Margrave (1) has reported a value of $\Delta_{sub}H°(298.15\ K)$ = 140.9±1 kcal mol^{-1} but details are not yet available. Assuming that this corresponds to reaction A below, we calculate $\Delta_f H°(298.15\ K)$ = -75.5 kcal mol^{-1}. Firsova (2) reported two values of the sublimation pressure which were derived from Knudsen effusion data using auxiliary data for SiO(g). Porter (4) derived two pressures from a mass spectrometric study and also obtained a 2nd law value for $\Delta_{sub}H°$ from ion intensities. The resulting range for $\Delta_{sub}H°(298.15\ K)$, 136 to 141 kcal mol^{-1}, is consistent with the lower limit of 130 kcal mol^{-1}, obtained by Bergman (3) from a method involving explosion in a spherical bomb. An alternative analysis of the mass spectrometric data (4) using the gas phase reaction B suggests an even higher $\Delta_{sub}H°$ of 148 kcal mol^{-1}. The adopted $\Delta_f H°$ corresponds to $\Delta_{sub}H°(298.15\ K)$ = 143.4±8 kcal mol^{-1} and to $\Delta_{at}H(0\ K)$ = 297.3 ± 8 kJ mol^{-1}.

A. SiO_2(high cristobalite)= SiO_2(g) B. SiO(g)+1/2O_2(g) = SiO_2(g)

Heat Capacity and Entropy

Point group, ground state quantum weight and the linear symmetrical configuration are estimated by analogy with the properties of CO_2. From the bond lengths in SiO, CO_2 and CO, the length in SiO_2 is estimated as 1.509 x 1.160/1.128. Bond lengths and atomization energies for these molecules are reasonably consistent with the existence of six-electron bonds in the monoxides and four-electron bonds in the dioxides (5). Vibrational frequencies are estimated from a valence bond calculation using force constants, k = 9 x 10^5 and $k\delta/\ell^2$ = 0.3 x 10^5 dyne/cm, which are obtained from those of SiO, CO_2 and CO.

Point Group: C_{2v} $\sigma = 2$

Bond Distance: Ta-O = [1.69] Å Bond Angle: O-Ta-O = [110]°

Product of the Moments of Inertia: $I_A I_B I_C = [6.232542 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

Inghram, et al. (1) *and Krikorian and Carpenter* (2) *have presented mass spectrometric evidence indicating that the* predominant vapors in the vaporization of $Ta-Ta_2O_5$ mixtures in Ta Knudsen cells are TaO and TaO_2. As in the case with TaO(g) (5), the absolute pressures of TaO_2(g) calculated from both studies differ by a factor of roughly 1000 in the range 2022-2278 K (IPTS-68). Results of our 2nd and 3rd law analysis of these and other data are presented below.

Source	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law
(1)	A*	2	2022-2023	~	156.13	-	-	-39.47

(1)	C*	4	2022-2179	70.72	70.05	-0.3 ± 4.5	-49.44	-48.10
(2)	C	1	2271	~	81.03	-	-	-70.06
(3)	D	graph	1900-2860	-19.83	26.38	20.6 ± 2.8	-19.83	26.38

*Recalculated pressures using Otvis and Stevenson method for estimating ionization cross sections (2, 4); procedure increases $\Delta_r H°$ by ~ 3 kcal mol^{-1}.

A: 0.2 Ta(cr) + 0.4 Ta_2O_5(cr) = TaO_2(g) C: 0.5 Ta(cr) + 0.5 TaO_2(g) = TaO(g)

B: 0.2 Ta(cr) + 0.4 Ta_2O_5(ℓ) = TaO_2(g) D: Ta(cr) + O_2(g) = TaO_2(g)

As was observed in the TaO(g) table (5), the results of the 2nd and 3rd law analysis show considerable scatter. We adopt $\Delta_f H°(TaO_2, g, 298.15\ K) = -48.0$ kcal mol^{-1} based primarily on our analysis of the data from Inghram et al. (1) for the reaction 0.5 Ta(cr) + 0.5 TaO_2(g) = TaO(g). For this reaction we adopt a rounded result of $\Delta_r H°(298.15\ K) = 70.0$ kcal mol^{-1}. The adopted $\Delta_f H°(298.15\ K)$ value leads to a dissocation energy $D_0^0 = 15.3$ eV (3520 kcal mol^{-1}) for the process TaO_2(g) = Ta(g) + 2 O(g). This value is 1.8 times the dissociation energy of TaO(g) (5).

Heat Capacity and Entropy

The electronic levels and vibrational frequencies are those reported by Weltner and McLeod (7). The results were based on a matrix isolation study of TaO_2 trapped in argon and neon matrices at 20 K and 4 K, respectively. The infrared spectrum was interpreted to favor a bent molecule in the ground state. Kaufman et al. (8) reported that TaO_2(g) is bent based on the deflection of molecular beams of TaO_2 by an electronic quadrupole. This latter result is dependent, however, on there being no low lying electronic states. The bending frequency for the ground state has not been observed but is estiamted to be 300 cm^{-1} based on the observed ν_2 = 285 cm^{-1} value for the $^2A_1$ state (7). The Ta-O bond distance is estimated to be the same as in TaO(g) (5) *whereas the bond angle is estimated to be 110°.*

It should be noted that the Gibbs energy functions used here are roughly 2-4 cal K^{-1} g-atom^{-1} more positive those of Brewer and Rosenblatt (6) for linear TaO_2; the 3rd law $\Delta_r H°(298.15\ K)$ values in the above table would change by ~4.5 kcal mol^{-1}.

ANATASE (TiO_2) CRYSTAL M_r = 79.8788

$S°(298.15\ K) = 49.907 \pm 0.33\ J\ K^{-1}\ mol^{-1}$

T_{fus}(anatase → liquid) = [1949 ± 60 K]

$\Delta_f H°(0\ K) = -933.837 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -938.722 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [57.990]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of TiO_2(rutile) using $\Delta_r H°(968\ K) = -1.57 \pm 0.19$ kcal mol^{-1} for anatase → rutile. Navrotsky and Kleppa (1), using oxide-melt calorimetry, derived $\Delta_r H°$ from the difference in $\Delta_{sol} H°$ between anatase and rutile. Reduction of their value using JANAF enthalpies yields $\Delta_r H°(298.15\ K) = -1.44 \pm 0.3$ and $\Delta_f H°$(anatase, 298.15 K) = -224.36 ± 0.5 kcal mol^{-1}. Uncertainties in the enthalpies and in $\Delta_f H°$(rutile) contribute significantly to the overall uncertainty. Kybett and Margrave (2) derived $\Delta_f H°(298.15\ K) = -223 \pm 1$ kcal mol^{-1} from fluorine calorimetry. Their reaction was TiO_2(anatase) + 2 F_2(g) → TiF_4(cr) + O_2(g), but they gave no experimental data. Kybett's results for anatase and rutile may be combined to yield $\Delta_r H°(298.15\ K) = -2 \pm 1.4$ kcal mol^{-1} for anatase → rutile; this is consistent with the adopted value. Values for $\infty_r G° = \infty_r H°$ of -0.2 to -0.3 kcal mol^{-1} for anatase → rutile were derived by Schuiling and Vink (12) from relative solubilities in aqueous NaCl at 200° and 300°C. We suspect that this less negative result arises from saturating solid phases which differ in physical form and chemical composition from standard-state macrocrystalline anatase (see Phase Data).

Heat Capacity and Entropy

$C_p°$ below 300 K is based on data of Shomate (3, 52-296 K) and his Debye-Einstein extrapolation to absolute zero. The entropy is calculated by polynomial integration of $C_p°$ based on $S°(50\ K) = 0.45$ cal $K^{-1}\ mol^{-1}$.

$C_p°$ above 300 K is from constrained fitting of enthalpy data (739-1305 K) of Naylor (4). Naylor's points at 416 and 546 K are omitted due to positive bias in this temperature range. Enthalpy data (580-1001 K) of Lietz (5) deviate by -3.7 ± 1.2% at all temperatures. Similar discrepancies exist in Lietz' data for TiO_2(rutile). These discrepancies and the bias in Naylor's data near room temperature are discussed on the table for rutile (6). The choice between Naylor (4) and Lietz (5) is not clearcut, but we feel that Naylor's data lead to more reasonable values of $C_p°$. New data on a well-characterized sample are needed.

The two discrepant studies (4, 5) do agree that the enthalpy of anatase is slightly larger than that of rutile at all temperatures in the observed region. Our adopted $C_p°$ reproduces the approximate enthalpy difference between anatase and rutile as observed by each author (4, 5).

Phase Data

Both anatase and rutile have tetragonal crystal structures, but in anatase the elongated unit cell contains four molecules compared with two in the unit cell of rutile. Anatase transforms exothermally and irreversibly to rutile at temperatures above ≈1200 K (7-9). The rate of transformation is relatively slow and is governed by the nature and amount of impurities (7). Certain impurities markedly decrease the transformation temperature which can be as low as 700 K in the presence of an alkali flux (10). These observations led to the conclusion that anatase is a metastable phase which persists up to a temperature sufficient to activate the crystal rearrangement. This was confirmed by the calorimetric data of Navrotsky and Kleppa (1), who concluded that anatase is metastable with respect to rutile at all temperatures.

Lietz (5) reported a transition in anatase at ≈918 K based on his enthalpy data and on changes in prism angles measured by Schroder (11). We reject Lietz' T_{trs}, since his $\infty_{trs} H°$ is not distinguishable from his experimental scatter. Lietz' data for rutile and anatase exhibit remarkably similar deviations in this temperature region. Schroder's data have the same deficiency. Lattice parameter data (13) show scatter but no obvious change in this temperature range.

Characterization of anatase samples is particularly important for interpreting physical and chemical properties. Anatase precipitated from acidic sulfate solutions consists of agglomerates of very small crystals with large amounts of water and SO_3 (14). X-ray and electron diffraction show the major lines of anatase but fail to show the impurities, suggesting that the latter are present in noncrystalline form. These precipitates (14) lose water near 150°C and SO_3 near 650°C; crystal growth starts near 600°C. Precipitates from other media give anatase at lower temperatures (15), but calcination temperatures of at least 650°C are needed fror complete conversion of these precipitates into pure, macrocrystalline anatase. This suggests an alternative explanation for reports (5, 11) of T_{trs} ~645°C.

Fusion Data

T_{fus} is hypothetical in the sense that metastable anatase probably will convert to rutile (see Phase Data) before it can be superheated to the melting point. T_{fus} is calculated as the temperature at which $\Delta_r G° = 0$ for TiO_2(anatase) → TiO_2(ℓ). $\Delta_{fus} H°$ is the calculated difference in $\Delta_f H°$ at T_{fus}.

PREVIOUS: September 1966 CURRENT: December 1973

$S°(298.15\ K) = 50.292 \pm 0.17\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2130 \pm 20$ K (rutile → liquid)

$\Delta_f H°(0\ K) = -939.870 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -944.747 \pm 1.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [66.944 \pm 16.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ *is the value obtained by Mah et al. (1) a study by oxygen calorimetry. Eighteen combustions (1) of three well-*characterized samples of titanium metal led to a selected value of -225.8 ± 0.1 kcal mol^{-1}. This is comparable with other oxygen-combustion values of -225.5 ± 0.2 (2), -224.9 ± 0.4 (3) and -225.3 ± 0.3 (4) and a fluorine-combustion value of -225 ± 1 (5) derived from the reaction TiO_2(rutile) + 2 F_2(g) → TiF_4(cr) + O_2(g). No experimental data were given in the latter study (5).

The 1967 JANAF Table (6) assigned an uncertainty of ±1 kcal mol^{-1} to $\Delta_f H°$ due to possible uncertainty in corrections for oxygen deficiency in the rutile produced by combustion (1, 3). The atomic ratio O/Ti in the combustion product was determined by ignition to constant weight in air (1, 2) or in wet oxygen (3) at 1000°C. Ratios obtained were 1.985 to 1.994 (1), 2.00 (2) and about 1.95 (3). Mah's corrections to the stoichiometric composition correspond to about -0.8 to -1.7 kcal mol^{-1} in $\Delta_f H°$. Our opinion of the reliability of these corrections has changed due to new information on the crystal structure, $\Delta_f G°$ and $\Delta_f S°$ of oxygen-deficient compositions (7, 8). Mah's O/Ti ratios are at compositions where there appears to be hysteresis in measurements of the oxygen potential near 1300 K (7). The full range of the hysteresis corresponds to less than 20% of the oxygen potential. We assume that this percentage is an upper limit for error which might be introduced in the corrections of $\Delta_f G°$ and $\Delta_f H°$ from the observed O/Ti ratios to the stoichiometric composition. Thus, we assign an uncertainty of ±0.3 kcal mol^{-1} to $\Delta_f H° = -225.8$, but note that the less negative value of -224.9 ± 0.4 kcal mol^{-1} (3) is one of several alternatives for minimizing the deviation from integral values of $\Delta_r G°$ (7) relating rutile to Ti_3O_5 at 1304 K.

Heat Capacity and Entropy

$C_p°$ below 300 K is based on data of Sandin and Keesom (9, 0.3-20 K), Dugdale et al. (10, 12-270 K) and Shomate (11, 52-298 K). Smoothed values rather than data points were reported in the first two studies (9, 10) and only in the range 20-50 K by Dugdale (10). Dugdale's deviation plot indicates that the smooth curves (10, 11) agree within about ±0.3% above 77 K, but at lower temperatures the data of Shomate show a positive bias increasing to over 2% at 52 K. We adopt Dugdale's curve below 80 K and calculate S° by polynomial integrations of $C_p°$. The extrapolation below 0.3 K is insignificant. $C_p°$ data (69-295 K) of McDonald and Seltz (12) are omitted since they are roughly 3% higher than the adopted curve.

$C_p°$ above 300 K is from constrained fitting of enthalpy data (763-1746 K) of Naylor (13). The point at 394 K is omitted due *to positive bias (~6%) in the drop calorimeter at the lowest temperature; a similar bias is observed in Naylor's data for the four* other titanium oxides and in materials such as MgF_2 studied at nearly the same time. This bias and the low purity (97.9%) of Naylor's sample are unfortunate; they favor the selection of two more recent enthalpy studies (14, 15) which conflict with that of *Naylor. The adopted curve is favored, however, by four enthalpy points observed at 965 K by Navrotsky et al. (16) and by* comparisons with $C_p°$ for GeO_2, MnO_2, and V_2O_4, which have the same tetragonal-SnO_2 crystal structure as rutile.

Enthalpy data of Lietz (15, 578-1283 K) deviate from the adopted curve by ~-3% at all temperatures; similar deviations occur in his data for TiO_2(anatase). Data of Slyusar et al. (14, 645-1990 K) deviate by ~-4% below 1136 K and by -1.7 to +3.4% at higher temperatures. The discontinuity of almost 3% in the data near 1100 K seems to correspond to the temperature at which the authors switched container materials and temperature sensors (14). Data for Ti_2O_3, Ti_3O_5 and Ti_4O_7 (14) also have discontinuities in this region; the data below the discontinuity for Ti_2O_3 show a negative bias like rutile. Moreoever, the authors (14) report T_{fus} = 2014 K, which is ~100 too low for rutile. Other data are too scattered (17) and too uncertain (18, 19) to help resolve the difference with Naylor (13).

These discrepancies cause us to reject the data of Slyusar et al. (14) and to consider as coincidence the agreement with Lietz (15). These two data sets yield $C_p°$ values deviating from the adopted curve by -0.8 cal K^{-1} mol^{-1} at 700 K, 0.0 at 1100 K, and +3 at 2000 K. New data on a pure sample of rutile are needed to resolve the disagreement. We note that use of the rejected $C_p°$ curve is one of several alternatives for minimizing the deviation from equilibria (7) relating rutile to Ti_3O_5 at 1304 K.

Fusion Data - See the liquid table for details.

Sublimation Data

$\Delta_{sub} H°(298.15\ K) = 152.8 \pm 3$ kcal mol^{-1} is calculated from $\Delta_f H°(TiO_2, g)$. Sublimation makes TiO_2(cr) deficient in oxygen.

PREVIOUS: September 1966 CURRENT: December 1973

$S°(298.15\ K) = [72.345]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2130 \pm 20\ K$ (rutile → liquid)

$\Delta_f H°(298.15\ K) = [-894.055]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [66.944 \pm 16.7]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(TiO_2, \ell, 298.15\ K)$ is calculated from that of TiO_2(rutile) by adding $\Delta_{fus}H°$ to the difference in enthalpy, H°(2130 K)-H°(298.15 K), between rutile and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated as 8 cal K^{-1} g-atom^{-1} by comparison with MgF_2, $CaCl_2$, V_2O_4 and WO_3. Below the assumed glass transition at 1400 K, $C_p°$ is taken to be the same as that of TiO_2(rutile). S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°$.

Fusion Data

Schneider (1) reviewed eleven melting point studies and converted the values to IPTS-48. Eight of the results fall in the range 2113 ± 10 K for measurements in air. Brauer and Littke (2), using an atmosphere of oxygen-argon mixtures, found 2103 ± 15 K in air, 2113 ± 15 K with oxygen at 300 torr, 2133 ± 15 K at 500 torr and 2143 ± 15 K at higher oxygen pressures. The authors (2) interpreted the sharp increase in T_{fus} with increased oxygen pressure as being due to suppression of the oxygen deficiency in TiO_2. The residue of the sample melted in air gave an oxygen stoichiometry of 1.996 compared with 2.000 at higher oxygen pressures; the color showed a corresponding change from dark blue to bright yellow. The oxygen deficiency may have been even greater if there was significant reoxidation during cooling to room temperature. Schneider (1) questioned the attainment of black-body conditions in the temperature measurements; in fact, Brauer and Littke (2) tried to compensate for the change in sample color by use of similarly colored compounds in calibrations of the pyrometer. We wonder if this eliminated all relative bias in the melting temperatures.

T_{fus} = 2130 ± 20 K is adopted. This is intermediate between the data in air and those at highest oxygen pressures. $\Delta_{fus}H°$ is estimated such that $\Delta_{fus}S°$ = 7.5 cal K^{-1} mol^{-1}, or 2.5 cal K^{-1} g-atom^{-1}, based on observed data for isostructural V_2O_4. The resulting $\Delta_{fus}H°$ of 16 ± 4 kcal mol^{-1} may be compared with approximate values of $\Delta_{fus}H°$ derived from binary phase data. We obtain 12 kcal mol^{-1} from the binary with Al_2O_3 (3), 14 kcal mol^{-1} from BaO (4) and ZrO_2 (5), 16 kcal mol^{-1} from Ta_2O_5 (6) and 21 kcal mol^{-1} from WO_3 (7). These values are derived by calculating apparent $\Delta_{fus}H°$ values assuming activity coefficients of unity and then extrapolating the apparent values to (T_{fus}-T) = 0 in order to minimize activity effects. We omit other binary systems which deviate grossly from ideality. Uncertainties in the binary results are estimated to be about ±5 kcal mol^{-1}.

Point Group: C_{2v} $\sigma = 2$

Bond Distance: TiO = [1.62 ± 0.08] Å Bond Angle: O-Ti-O = 110° ± 15°

Product of the Moments of Inertia: $I_A I_B I_C = [3.115429 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H° = -73.0 \pm 3$ kcal mol^{-1} is selected from the ten data sets analyzed below. These include four different reactions studied by Knudsen effusion or mass spectrometry. Our adopted value is consistent with all but two of the data sets, namely reactions C (2) and D (5). We presume that the less negative $\Delta_f H°$ = -59.1 from reaction C is due to bias in the mass-spectrometric values (2) for the partial pressure of O(g). The more negative $\Delta_f H°$ = -86.0 from the sublimation reaction D corresponds to effusion pressures too large by a factor of ~25; allowance for the activity of TiO_2 in the oxygen-deficient condensed phase (5) increases the discrepancy. Gross mass transport from the cell by species other than TiO_2 may have occurred (3), since mass-spectrometric pressures (3, 6) are fairly consistent with our $\Delta_f H°$. We give little weight to reactions D and E due to problems in interpretation of the vapor composition (5, 8) and the activity of oxygen-deficient TiO_2(cr, ℓ).

Activity effects appear to be minor for TiO_2 in TiO_x(cr) in the range 1.833 < x < 1.889. Univariant, two-phase systems involving the crystals Ti_6O_{11}, Ti_7O_{13}, Ti_8O_{15} and Ti_9O_{17} occur in this region. Our calculations based on emf data (9) yield $a(TiO_2) \geq$ ~0.7 at 1900 K; these values change only slowly with x and T. Sublimation experiments in this region may involve hysteresis, but the degree should be less than that found in equilibrium data (10) near 1300 K.

Drowart et al. (11) provided the key improvement in $\Delta_f H°$ by reinterpretation of the congruent vaporization (4) of Ti_3O_5(cr). Gilles and co-workers (1, 12) confirmed the congruency of vaporization and gave supportive mass-spectrometric data. We use JANAF auxiliary data (7) with D°(TiO) = 158.5 ± 2 kcal mol^{-1} to recalculate the vaporization (4) as described in (1, 11). Resulting partial pressures of TiO_2, TiO and O(g) are analyzed in terms of reaction C. Third-law analysis yields our selected value of $\Delta_f H°$ and $D°(TiO_2)$ = 302.8 ± 3 kcal mol^{-1}. D° would decrease by ~1 kcal mol^{-1} if D°(TiO) were increased by 2 kcal mol^{-1} in the recalculation. The conclusion (1) that the ionization cross-section ratio (TiO/TiO_2) = 2.2 is unchanged in our recalculation; even larger ratios may be expected at low ionizing potentials (13).

[a]Reactions are A) $TiO_2(g) + Ti(g) = 2\ TiO(g)$ B) $TiO(g) + WO_3(g) = TiO_2(g) + WO_2(g)$ C) $TiO_2(g) = TiO(g) + O(g)$
D) TiO_2(rutile) = $TiO_2(g)$ E) $TiO_2(\ell) = TiO_2(g)$

Heat Capacity and Entropy

The electronic levels, bond angle and stretching frequencies are from infrared and emission spectra of TiO_2 isolated in rare-gas matrices (14). We assume the emission at 5295 Å to be a forbidden triplet-singlet transition due to its similarity with CeO_2 (15). Frequency ν_1 was observed both in infrared and emission spectra. The bond angle was derived (14) from ν_3 using splittings observed for the five Ti isotopes. Earlier electric-deflection experiments (16) at 2500 K had shown that the populated electronic states were polar (i.e., nonlinear). We estimate the bond length to be the same as that of ground-state TiO (7). Principal moments of inertia are: $I_A = 2.7500 \times 10^{-39}$, $I_B = 9.3573 \times 10^{-39}$ and $I_C = 12.1072 \times 10^{-39}$ g cm^2.

The bending frequency is estimated as 270 ± 80 cm^{-1} from the following information. A value of 272 cm^{-1} derived from the three-constant valence-force field (17) using ν_1, ν_3 and $(k\delta/\ell^2)/k_1$ = 0.040 transferred from isoelectronic CaF_2 (18). The resulting value of k_{12}/k_1 is similar to that of CaF_2. The inferior two-constant central-force field gives ν_2 = 325 cm^{-1}. Bending modes have been observed (19) for electronic states of TaO_2 (285 and 281 cm^{-1}) and WO_2 (300 cm^{-1}). These molecules have stretching frequencies similar to TiO_2, but the excited states may be linear rather than bent as are the ground states. We estimate that S°(298.15 K) is uncertain by about 0.7 and 0.3 cal K^{-1} mol^{-1} due to uncertainties in ν_2 and the geometry, respectively.

Enthalpy of Formation

Four independent mass spectrometric studies lead to values for $\Delta_f H°(VO_2, g, 298.15\ K)$ (1, 2, 3, 4). Shchukarev et al. (2) studied the composition of the vapor above V_2O_4 during evaporation from the surface of a platinum strip. A 2nd law sublimation heat, $\Delta_{sub}H° = 104 \pm 2$ kcal mol^{-1}, was reported for the range 1500-1800 K. Assuming the reported value corresponds to 1700 K and using auxiliary data (5), we calculate $\Delta_f H°(VO_2, g, 298.15\ K) = -62.3 \pm 2.0$ kcal mol^{-1}. The sublimation was described by 0.5 $V_2O_4(cr) = VO_2(g)$. More recent related work (3) yields a $\Delta_f H°(298.15\ K)$ value approximately 6 kcal mol^{-1} more positive. This latter work and other investigations are summarized in the following table.

Reference	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law

(1)	C	2	1948	-	-16.23	-	-	-45.97
(4)	C	1	2270	-	-12.86	-	-	-49.34
(4)	D	1	2270	-	-40.14	-	-	-32.94 (-39.79)**

**Value is based on recent determination by Farber et al. (8) for $\Delta_f H°(AlO, g, 298.15\ K)$.

Reactions: (A) 0.5 $V_2O_4(cr) = VO_2(g)$ (C) $V(g) + VO_2(g) = 2\ VO(g)$

(B) 0.5 $V_2O_4(\ell) = VO_2(g)$ (D) $2\ AlO(g) + V(g) = 2\ Al(g) + VO_2(g)$

We adopt $\Delta_f H°(298.15\ K) = -55.6$ kcal mol^{-1} for $VO_2(g)$. This value is an average of the 2nd and 3rd law results of Frantseva and Semenov (3). These results are independent of the VO(g) data and show small third law drifts. The results of our analysis for reaction (C) for the data of Berkowitz et al. (1) and Farber et al. (4) show good agreement in $\Delta_r H°(298.15\ K)$ but lead to values for $\Delta_f H°(298.15\ K)$ which are 6-10 kcal mol^{-1} less negative than our adopted value. Killingbeck (6) studied the evaporation of V_2O_3 from a molybdenum effusion chamber and reported $\Delta_r H°(298.15\ K) = 279.5 \pm 5$ kcal mol^{-1} for $V_2O_3(cr) = VO(g) + VO_2(g)$. Using auxiliary data (5) we calculate $\Delta_f H°(298.15\ K) = -42.3 \pm 5.0$ kcal mol^{-1} for $VO_2(g)$.

The adopted $\Delta_f H°(298.15\ K)$ value corresponds to a dissociation energy $D° = 295.5$ kcal mol^{-1} (12.8 eV) for the process $VO_2(g) = V(g) + 2\ O(g)$. This D° value is 1.96 times the dissociation energy of VO(g) (5).

Heat Capacity and Entropy

The vibrational frequencies and geometry of $VO_2(g)$ are estimated based on existing and estimated data for related metal dioxides such as $TiO_2(g)$, $TaO_2(g)$ and $WO_2(g)$ (5). The V-O bond distance is assumed to be the same as in VO(g) (5).

The ground state quantum weight of 2 is adopted so as to be consistent with $TaO_2(g)$ (5). This introduces an uncertainty of ±1.38 cal K^{-1} mol^{-1} in S°(298.15 K). The estimation of ν_2 at 300 cm^{-1} results in an uncertainty of 0.72 cal K^{-1} mol^{-1} in S°(298.15 K) for ±100 cm^{-1}. The estimates for $VO_2(g)$ are such that the 3rd law drifts as indicated in the above table are small. Nevertheless, until more data are available for $VO_2(g)$, the uncertainty in the entropy must be considered as ±1.4 cal K^{-1} mol^{-1} for a bent molecule. The free energy functions suggested by Brewer and Rosenblatt (7) are roughly 3-4 cal K^{-1} mol^{-1} lower than those adopted here. The main reason for the difference is that Brewer and Rosenblatt (7) treated $VO_2(g)$ as a linear molecule.

The electronic levels of the V^{+4} ion as reported by Moore (9) consist of a ground state with quantum weight four and an excited state at 620 cm^{-1} with a quantum weight six. The next excited state is listed at ~148000 cm^{-1}. Inclusion of an estimated state for $VO_2(g)$ at 620 cm^{-1} with a quantum weight of six would raise S°(298.15 K) by 1.06 cal K^{-1} mol^{-1}. This is within the estimated uncertainty of S°(298.15 K).

PREVIOUS: December 1973 (1 atm) CURRENT: December 1973 (1 bar)

$S°(298.15\ K) = 50.528 \pm 0.29\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -584.745 \pm 0.88\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -589.693 \pm 0.88\ kJ\ mol^{-1}$
$\Delta_{sub} H°(298.15\ K) = 666.260\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation, -140.94 ± 0.21 kcal mol^{-1}, was determined by combustion calorimetry by Mah (1). Griffis (2) has measured the enthalpy of combustion to WO_3(cr) which yields $\Delta_f H°(WO_2, cr, 298.15\ K) = -139.8 \pm 1.5$ kcal mol^{-1}. When recalculated with $\Delta_f H°(WO_3, cr, 298.15\ K) = -201.46$ kcal mol^{-1}. This result is less certain because of the incomplete characterization of the final products.

Recent equilibrium data yield essentially the same average of the enthalpy of formation by the 3rd law method. The results are presented as follows.

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 3rd law	2nd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(3)	A	1275-1497	10	2.672	0.036	1.9 ± 0.6	-140.62
(3)	B	973-1467	6	11.994	12.076	0.2 ± 0.76	-139.58
(4)	C	923-1223	7	-70.281	-67.943	-2.2 ± 0.2	-140.56
(5)	B	1075-1210	5	12.949	13.051	-0.1 ± 0.4	-141.49
(6)	B	873-1273	30	12.550	10.295	2.1 ± 0.1	-140.70

Reactions:
A) $1/2\ WO_2(cr) + CO(g) = 1/2\ W(cr) + CO_2(g)$
B) $1/2\ WO_2(cr) + H_2(g) = 1/2\ W(cr) + H_2O(g)$
C) $1/2\ W(cr) + 1/2\ O_2(g) = 1/2\ WO_2(cr)$

Heat Capacity and Entropy

King et al. (7) have measured the low temperature heat capacities (53-297 K) and high temperature enthalpy changes (396-1800 K) by drop calorimetry. The low temperature and high temperature heat capacities were joined smoothly at 298.15 K. The entropy was obtained from the heat capacities based on $S°(51\ K) = 0.52$ cal K^{-1} mol^{-1}. It is possible that at temperatures below 50 K the entropy due to the uncoupling of the d^2 electrons will appear contributing an additional 1.3 cal K^{-1} mol^{-1}.

Decomposition Data

Tungsten dioxide (cr) has no melting point since disproportionation occurs to yield W(cr) and $WO_3(\ell)$ before melting starts. T_{dcm} = 1997 K is calculated as the temperature at which $\Delta_f G° = 0$ for $3\ WO_2(cr) = 2\ WO_3(\ell) + W(cr)$.

Sublimation Data

The enthalpy of sublimation is calculated from the difference between the enthalpies of formation of $WO_2(g)$ and $WO_2(cr)$.

Bond Angle: O-W-O = [110]°

Product of the Moments of Inertia: $I_A I_B I_C = [9.435202 \times 10^{-115}]\ g^3\ cm^6$

Enthalpy of Formation

DeMaria et al. (1) have reported the partial pressures of WO(g), WO_2(g), WO_3(g), and O(g) in a mass spectrometric study of aluminum oxide vaporized from a tungsten cell from 2188 to 2475 K. The adopted value, $\Delta_f H°(WO_2, g, 298.15\ K) = 18.3 \pm 7$ kcal mol^{-1}, was calculated from $\Delta_r H°(298.15\ K) = -100.9$ kcal mol^{-1} for W(cr) + 2 O(g) → WO_2(g), which was obtained from 3rd law treatment of their partial pressure data, using all JANAF functions. The 3rd law drift is 15.0 ± 5.2 cal K^{-1} mol^{-1}. Partial pressures of WO_2(g), WO_3(g) and O(g) at 2242 K have also been reported by Chupka et al. (2) in a mass spectrometric study of beryllium oxide in a tungsten cell. Similar calculation gives $\Delta_r H°(298.15\ K) = -105.9$ kcal mol^{-1} which yields $\Delta_f H°(WO_2, g, 298.15\ K) = 13.2$ kcal mol^{-1}.

Heat Capacity and Entropy

The WO_2(g) was assumed to have a C_{2v} symmetry with a bond angle O-W-O = 110°. The bond distance W-O was estimated to be the same as that in WO(g). The symmetric and asymmetric stretching frequencies were obtained from the infrared spectrum of WO_2 in a neon matrix by Weltner and McLeod (3). The bending vibrational frequency (300 cm^{-1}) was estimated by comparison with other dioxides. The electronic levels and quantum weights were estimated from W^{+4} ion by analogy with Mo^{+4} ion. The principal moments of inertia are: $I_A = 4.8780 \times 10^{-39}$, $I_B = 11.6809 \times 10^{-39}$ and $I_C = 16.5589 \times 10^{-39}$ g cm^2.

PREVIOUS: September 1966 (1 atm) CURRENT: September 1966 (1 bar)

TUNGSTEN OXIDE ($WO_{2.72}$) CRYSTAL M_r = 227.3684

$S°(298.15\ K) = [68.425]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -781.153 \pm 2.1\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation, -186.7 ± 0.5 kcal mol^{-1}, is derived from recent equilibrium data which are in excellent agreement, the results are summarized below. In addition, Griffis (1) measured the enthalpy of combustion to WO_3(cr) which yields $\Delta_f H°(WO_{2.72}, cr, 298.15\ K) = -185.4 \pm 1$ kcal mol^{-1} when recalculated with $\Delta_f H°(WO_3, cr, 298.15\ K) = -201.46$ kcal mol^{-1}. This result is less certain because of the incomplete characterization of the final products. The emf data reported by Gerasimov et al. (2) give the value of -186.89 kcal mol^{-1} for the enthalpy of formation at 298.15 K. Ackermann and Rauh (3) have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy and X-ray diffraction. *In the temperature range from 1300 to 1600* K, they have derived indirectly from their measurements the enthalpy of formation -182.2 kcal mol^{-1} (corresponding to -187.2 kcal mol^{-1} at 298.15 K, using the JANAF functions).

Source	Reaction*	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(4)	A	830-1048	5	2.951	4.095	1.2 ± 0.2	-186.65
(5)	B	1173-1423	-	-45.739	-	-	-186.68
(6)	A	904-1066	4	2.676	4.279	1.6 ± 0.3	-186.83
(7)	A	873-1173	24	4.314	4.314	-0.01± 0.06	-186.87

A) $100/72\ WO_{2.72}(cr) + H_2(g) = 100/72\ WO_2(cr) + H_2O(g)$

B) $WO_2(cr) + 0.72\ O_2(g) = WO_{2.72}(cr)$

Heat Capacity and Entropy

The monoclinic unit cell of $WO_{2.72}$ corresponds to $W_{18}O_{49}$ as shown by the X-ray diffraction studies of Magneli et al. (8). The tabulated heat capacities of $WO_{2.72}$(cr) were estimated from those of WO_2(cr) and WO_3(cr) because all three have similar monoclinic structures as identified by Magneli et al.

The entropy, $S°(298.15\ K) = 16.35$ cal K^{-1} mol^{-1}, was calculated from $\Delta_r S°(298.15\ K) = 7.96 \pm 0.09$ cal K^{-1} mol^{-1} for reaction A, using all JANAF values. The value of $\Delta_r S°(298.15\ K)$ was derived from the 2nd law analysis of Griffis' data (7).

$S°(298.15\ K) = [73.371]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -820.064 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpy of formation, -196.0 ± 3 kcal mol^{-1}, is a weighted average of those derived from equilibrium data, in addition the following results have been reported.

Griffis (1) has measured the enthalpy of combustion to WO_3(cr) which yields -195.6 kcal mol^{-1} when recalculated with $\Delta_f H°(WO_3, cr, 298.15\ K)$ = -201.46 kcal mol^{-1}. This result is less certain because of the incomplete characterization of the final products. Ackermann and Rauh (2) have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and x-ray diffraction. In the temperature range from 1300 to 1600 K, they have derived indirectly two values of $\Delta_f H°(WO_{2.90}, cr)$ = -190.9 and -188.0 kcal mol^{-1} (corresponding to -196.1 and -193.3 kcal mol^{-1}, respectively, at 298.15 K, using all JANAF functions).

Reactions:
A) $WO_3(cr) + 0.1\ H_2(g) = WO_{2.90}(cr) + 0.1\ H_2O(g)$
B) $WO_{2.90}(cr) + 0.18\ H_2(g) = WO_{2.72}(cr) + 0.18\ H_2O(g)$
C) $WO_{2.90}(cr) + 0.9\ H_2(g) = WO_2(cr) + 0.9\ H_2O(g)$
D) $WO_{2.90}(cr) + 0.05\ O_2(g) = WO_3(cr)$
E) $WO_{2.72}(cr) + 0.09\ O_2$ [illegible] $= WO_{2.90}$[illegible]

Heat Capacity and Entropy

The monoclinic unit cell of $WO_{2.90}$ corresponds to $WO_{20}O_{58}$ as shown by the X-ray diffraction studies of Magneli et al. (7). The tabulated heat capacities and the entropy, S°(298.15 K) = 17.536 cal K^{-1} mol^{-1}, were estimated from those of WO_2(cr) and WO_3(cr) because all three have the similar monoclinic structure as identified by Magneli et al. (7).

TUNGSTEN OXIDE ($WO_{2.96}$) CRYSTAL M_r = 231.2082

$S°(298.15\ K) = [74.894]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -834.959 \pm 12.6\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted value, $\Delta_f H°(WO_{2.96}, cr, 298.15\ K) = -199.56\ kcal\ mol^{-1}$, was obtained by 3rd law treatment of $\Delta_f G° = 191{,}600 + 54.0\ T\ (cal\ K^{-1}\ mol^{-1})$ in the temperature range from 1300 - 1550 K, using all JANAF functions. The equation for $\Delta_f G°$ was reported by Ackermann and Rauh (1), based on studies by mass spectroscopy and X-ray diffraction. In this study, $\Delta_f G°$ was obtained by comparison of the Gibbs free energies of sublimation (to gaseous W_2O_6, W_3O_8, W_3O_9 and W_4O_{12}) over the two systems $W-WO_2(cr)$ and $WO_{2.96}(cr)$ and $WO_{2.96}(cr)$; thus $WO_{2.96}(cr)$ was related to $WO_2(cr)$ through the gaseous species.

Battles (2) has reported partial pressures of $W_3O_9(g)$ and $W_4O_{12}(g)$ in equilibrium with $WO_3 - WO_{2.90}(cr)$. In light of Ackermann and Rauh's observation, the condensed phase was presumed to have the composition of $WO_{2.96}(cr)$. The pressure data are in reasonable agreement with the studies of Ackermann and Rauh as summarized below. Values of $\Delta_f H°(WO_{2.96}, cr, 298.15\ K)$ derived from the data of Battles are based on the same author's data for $W_3O_9(g)$, and $W_4O_{12}(g)$ in order to relate $WO_{2.96}$ to WO_2 directly.

B) $WO_{2.99}$ [illegible] r) = 0.29333 $W_3O_9(g)$ + 0.04 $W_3O_8(g)$
C) $WO_{2.96}$ [illegible] = 0.22 $W_4O_{12}(g)$ + 0.04 $W_3O_8(g)$

Heat Capacity and Entropy

The tabulated heat capacities and the entropy at 298.15 K were es[illegible]amted from those of $WO_2(cr)$ and $WO_3(cr)$.

Ackermann and Rauh (1) have found that the composition $WO_{2.96}$ probab y represents the azeotropic composition of the WO_{3-x} solid solution and is the only single phase which evaporates congruently below 1550 K.

Tungsten Oxide ($WO_{2.96}$) $O_{2.96}W_1(cr)$

ZIRCONIUM OXIDE (ZrO_2) CRYSTAL M_r = 123.2188

$S°(298.15\ K) = [50.359 \pm 0.33]\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 1478 \pm 5\ K$

$T_{fus} = 2950\ K$

$\Delta_f H°(0\ K) = -1092.032 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1097.463 \pm 1.7\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 5.941 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [87.027]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(ZrO_2, cr, 298.15\ K) = -262.3 \pm 0.4$ kcal mol^{-1} is an average of the values 261.5 ± 0.2 kcal mol^{-1} and -263.1 ± 0.5 kcal mol^{-1} *measured (by combustion calorimetry)* by Humphrey (1) and Huber et al. (2), respectively. Also the enthalpy of formation was measured calorimetrically by Neumann et al. (3), Roth et al. (4) and by Sieverts et al. (5) and was found to be -258.2, -258.8 and -256.1 kcal mol^{-1}, respectively. However, more weight was given to the Humphrey and Huber values.

Heat Capacity and Entropy

The low temperature heat capacities, 54.3-295 K, were measured by Kelley (6). The heat capacities in the temperature range 298-1478 K were calculated by using the Coughlin and King (7) equation, $C_p° = 16.64 + 1.80 \times 10^{-3}T - 3.36 \times 10^5\ T^{-2}$, obtained from their measured enthalpy data (296.8-1841 K). The values from the two sources join smoothly at 298.15 K. Above the transition 1478 K, the heat capacity was taken as constant at 17.80 cal $K^{-1}\ mol^{-1}$. The entropy was calculated at 54.30 K using the Debye and Einstein function D(345/T) + E(513/T) + E(861/T) given by Kelley (6). The value, S°(54.3 K) = 0.5507 cal $K^{-1}\ mol^{-1}$, is thus calculated.

Transition Data

T_{trs} and $\Delta_{trs}H°$ were taken from Coughlin and King (7).

Fusion Data

T_{fus} and $\Delta_{fus}H°$ were taken from U. S. Nat. Bur. Stand. (8).

PREVIOUS: June 1961 CURRENT: December 1965

ZIRCONIUM OXIDE (ZrO_2) LIQUID M_r = 123.2188

$S°(298.15\ K) = [74.657]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2950\ K$

$\Delta_f H°(298.15\ K) = [-1023.155]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [87.027]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(ZrO_2, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(ZrO_2, cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, H°(2950 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2000 K. The heat capacity below 2000 K was obtained from the heat capacity of the crystal. Above 2000 K the heat capacity was assumed constant and estimated to be 21.0 cal $K^{-1}\ mol^{-1}$ or 7 cal $K^{-1}\ mol^{-1}$ per g-atom as suggested by Kubaschewski and Evans (1). The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap}(1 atm) = 4548 K is calculated as the temperature at which the fugacity is 1 atm for the reaction $ZrO_2(\ell) + ZrO_2(g)$. The difference between $\Delta_f H°(4548\ K)$ for $ZrO_2(g)$ and $ZrO_2(\ell)$ gives $\Delta_{vap} H°(4548\ K) = 149.2\ kcal\ mol^{-1}$.

ZIRCONIUM OXIDE (ZrO_2) IDEAL GAS M_r = 123.2188

$S°(298.15\ K) = 273.746\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -284.01 \pm 46.0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -286.19 \pm 46.0\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
884 (1)
[137](1)
818 (1)

Ground State Quantum Weight: 1 $\sigma = 2$
Point Group: C_{2v}
Bond Distance: O-Zr = 1.711 Å
Bond Angle: O-Zr-O = 109°
Product of the Moments of Inertia: $I_A I_B I_C = 5.682779 \times 10^{-115}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(ZrO_2, g, 298.15\ K) = -68.4 \pm 11\ kcal\ mol^{-1}$ was calculated from the $\Delta_r H°(298.15\ K) = 193.867 \pm 11.25\ kcal\ mol^{-1}$ for the reaction $ZrO_2(cr) \rightarrow ZrO_2(g)$. The value of $\Delta_r H°(298.15\ K)$ was obtained by the 3rd law method using the determined vapor pressures (at the range 2331-2480 K) by Chupka et al. (1). They observed the variation of the ZrO_2^+ ion intensity over ZrO_2 and reported equilibrium constants for the reaction $ZrO_2(cr) \rightarrow ZrO_2(g)$ in the range 2331-2480 K. The 3rd law drift is 80 ± 23 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

The vibrational frequencies ν_1 = 884, ν_2 = [137], ν_3 = 818 and angle O-Zr-O = 109° were obtained from Linevsky (2). The bond distance r_e(O-Zr) = 1.711 Å was obtained from Uhler and Akerline (3). The principal moments of inertia are: $I_A = 3.8834 \times 10^{-39}$, $I_B = 10.3101 \times 10^{-39}$, $I_C = 14.1935 \times 10^{-39}\ g\ cm^2$.

Enthalpy of Formation

Gunther et al. (1) measured ΔE for the reaction $O_3(g) \rightarrow 3/2\ O_2(g)$ in a calorimeter calibrated by means of the reaction $CO(g) + 1/2\ O_2(g) \rightarrow CO_2(g)$ and found the ratio of the ΔE values for these reactions to be 0.5077 ± 0.0024. The temperature of the experiments is not reported and is assumed to have been 18°C. From the above ratio, $\Delta_f H°(298.15\ K)$ is calculated to be 33.89 ± 0.36 cal mol^{-1}. Kailan and Jahn (2) measured $\Delta_r H°$ at an unspecified temperature for the reaction $O_3(g) \rightarrow 3/2\ O_2(g)$ in an electrically calibrated calorimeter. If the temperature of the experiments is assumed to have been 18°C and the current joule-calorie conversion factor is used, $\Delta_f H°(298.15\ K)$ is found to be 34.3 ± 0.6 kcal mol^{-1}. Variability in the O_3 content of the feed gas is allowed for in the uncertainty. The value adopted here is 34.1 ± 0.4 kcal mol^{-1}.

Heat Capacity and Entropy

Gordon (3) has calculated the thermodynamic functions from 298.15 to 6000 K by the method of Pennington and Kobe (4) which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from Pierce (5). The functions below 298.15 K have been calculated for a rigidly rotating harmonic oscillator.

LEAD SILICATE ($PbSiO_3$) CRYSTAL M_r = 283.2837

$S°(298.15\ K) = 109.927 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1037\ K$

$\Delta_f H°(0\ K) = -1138.091 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1144.993 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of the reaction PbO(red) + SiO_2(cr) → $PbSiO_3$(cr) was reported by Kelley (1). This value for the enthalpy of reaction of the oxides has been converted to the enthalpy of formation using JANAF auxiliary data (4). The above $\Delta_r H°(298.15\ K) = -3.75 \pm 0.12\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

In the low temperature region (53.25-298.15 K) the $C_p°$ values are those determined by King (2). Above 298.15 $C_p°$ values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.25 K using the Debye and Einstein functions D(140/T) + E(213/T) + 2E(596/T) + E(1440/T) given by King (2). $S°(53.25\ K) = 3.662\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} was taken from Geller et al. (3).

SULFUR TRIOXIDE (SO_3) IDEAL GAS M_r = 80.0582

$S°(298.15\ K) = 256.769\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -390.025 \pm 0.71\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -395.765 \pm 0.71\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}
1068 (1)
495 (1)
1391 (2)
529 (2)

Ground State Quantum Weight: 1 $\sigma = 6$

Point Group: D_{3h}

Bond Distance: S-O = 1.43 Å

Bond Angle: O-S-O = 120°

Product of the Moments of Inertia: $I_A I_B I_C = 1.0824273 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

The enthalpy of formation is calculated from the reaction $SO_2 + 1/2\ O_2 \rightarrow SO_3$ for which three sets of equilibrium constants are available. A summary of the 2nd and 3rd law treatment of the data is given below.

Source	T/K	Data Points	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
(1)	933- 945 K	5	-27.67±2.7	-23.608	3.7±2.9
(2)	801-1170 K	8	-23.45±0.1	-23.661	-0.8±0.1
(3)	850-1001 K	11	-22.74±0.6	-23.614	-1.5±0.6
*	801-1170 K	23*	-23.40±0.2	-23.638	-0.9±0.2

*Combination of above references with one point omitted due to failure of a statistical test.

The combined set was adopted though it appears that the three sets are not in excellent agreement, and the combination heavily favors reference 2. Although there is a definite trend in all the data, it cannot be considered definitive enough for use in the modification of the SO_3 functions.

Heat Capacity and Entropy

The bond length and angles are taken from the electron diffraction data of Palmer (4). The vibrational frequencies are taken from the infrared studies of Lovejoy et al. (5) which are in excellent accord with those of Bent and Ladner (6) using different techniques. These values differ from the assignment used by Stockmayer et al. (7) in their analysis of the thermodynamic properties of SO_3.

The principal moments of inertia are: $I_A = I_B = 8.1493 \times 10^{-39}\ g\ cm^2$ and $I_C = 16.2987 \times 10^{-39}\ g\ cm^2$.

PREVIOUS: September 1965 (1 atm) CURRENT: September 1965 (1 bar)

$S°(298.15\ K) = 77.253 \pm 0.21\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 470 \pm 20\ K$
$T_{fus} = 2115 \pm 10\ K$

$\Delta_f H°(0\ K) = -1512.287 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1520.884 \pm 8.4\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 1.138\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [105]\ kJ\ mol^{-1}$

Enthalpy of Formation

Humphrey (1) measured $\Delta_r H°(298.15\ K) = -88.11 \pm 0.1$ kcal mol^{-1} for the reaction $Ti_2O_3(cr) + 0.5\ O_2(g) = 2\ TiO_2$(rutile) using bomb calorimetry. When combined with $\Delta_f H°(298.15\ K) = -225.8$ kcal mol^{-1} for rutile, this yields -363.5 ± 2 kcal mol^{-1} as the adopted $\Delta_f H°(298.15\ K)$ for Ti_2O_3. The less negative value of -362.8 ± 0.8 kcal mol^{-1} was obtained by Ariya et al. (2) from their heats of combustion of various compositions in the Ti-O system. Ariya et al. (2) used an estimated correction for the formation of TiO_{2-x}, while Humphrey (1) obtained values of 0.1 to 1.3 kcal mol^{-1} by grinding the product and reburning it with while oil. Most of the assigned uncertainty arises from this problem [see TiO_2(rutile) for further details].

Heat Capacity and Entropy

$C_p°$ is based on data of Sjostrand and Keesom (3, 0.4-20 K) and Paukov and Berezovskii (4, 12-305 K). The two sets of data disagree in the region of overlap. Paukov (4) appears to have a positive bias at the lowest temperatures (12-18 K), so we adopt a curve which shifts gradually from Sjostrand at 10 K to Paukov at 30 K. Deviations of Paukov (4) from the adopted $C_p°$ are +36% (12 K) and +3% (20 K). Earlier data of Shomate (5, 53-296 K) deviate by +0.6% to +4.1% with extreme deviations of 3.0% at 53 K and 2.9 to 4.1% in a "hump" observed by Shomate near 240 K. No hump was found by Paukov. S° is derived from $C_p°$ based on an extrapolation which is negligible.

$C_p°$ between 298 K and 470 K is a smooth extrapolation of the low-temperature curve using the approximate shape found by Barros et al. (6, 150-700 K) via differential scanning calorimetry (Perkin-Elmer DSC-1B). The DSC data (6) have a positive bias of ~10%, over twice as large as we might expect for this apparatus so the results do not help establish $C_p°$ between 298 K and T_{trs}. Data measured by a conduction-type calorimeter (7, 323-523 K) have a large negative bias near 400 K. Drop-calorimetric data (8, 375-472 K) deviate from the adopted enthalpies by +5 to +2%.

$C_p°$ above the λ-transition is derived from enthalpy data (8, 487-1750 K) by fitting only the region above 549 K. Maximum deviations from the adopted cruve are ±0.4% in the fitted region and +0.9% at 526 K. Enthalpy data (493-1082 K) reported graphically by Erofeeva et al. (9) deviate by about -6 to -2%.

Slyusar et al. (15) recently reported new enthalpy data for Ti_2O_3, Ti_3O_5, Ti_4O_7 and TiO_2. The new data for Ti_3O_5 and TiO_2 are in reasonable agreement with existing JANAF Tables (16), but those for Ti_2O_3 cross the adopted values near 1100 K and deviate by -4.5 ± 1% (672-878 K) and +3.4 ± 1.1% (1158-2027 K). The transition vanishes for Ti_2O_3 samples doped with 4% V_2O_3 (6) and may be affected by other impurities or non-stoichiometry. We feel that Slyusar et al. (15) have not characterized their sample adequately. We tentatively reject their data pending new measurements on a well-characterized sample.

Transition Data

We arbitrarily choose $T_{trs} = 470 \pm 20$ K and derive $\Delta_{trs} H°$ as the difference between the adopted enthalpy curves at that temperature. Reported values of $\Delta_{trs} H°$ include 0.380 ± 0.025 (6), 0.036 (7) and 0.215 kcal mol^{-1} (8); each derives from different data and difference base lines.

Convenience dictates that we treat the electrical transition as first order although recent $C_p°$ data (6) suggest a gradual λ-type anomaly peaking near 470 K and extending from about 380 to 560 K. There is no change in the corundum-type symmetry, but the lattice parameters shift rapidly in this temperature range (10, 11). Honig (11) summarized evidence on the nature of the change from semiconductor to semimetal and noted that the transition can be explained without invoking antiferromagnetic ordering. Recent studies (6, 12-14) are consistent with this interpretation.

Fusion Data

See the liquid table for details.

PREVIOUS: June 1967 CURRENT: June 1973

TITANIUM OXIDE (Ti_2O_3) LIQUID M_r = 143.7582

$S°(298.15\ K) = [127.126]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2115 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [-1418.459]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [105]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Ti_2O_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2115 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated as 7.5 cal K^{-1} g-atom^{-1}. Below the assumed glass transition at 1400 K, $C_p°$ is taken from the crystal; the high-temperature curve is extrapolated down to 298.15 K. S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°(298.15\ K)$.

Fusion Data

T_{fus} is the value quoted by Wahlbeck and Gilles (1) based on work of K. D. Carlson. The adopted value is converted to IPTS-68. $\Delta_{fus}H°$ is estimated such that $\Delta_{fus}S°$ is 12 cal K^{-1} mol^{-1} as observed (2) for Al_2O_3(α, corundum). Other reported melting points were summarized earlier (3). Slyusar et al. (4) recently obtained T_{fus} = 2043 K in an enthalpy study, but we tentatively reject this work (see Ti_2O_3, crystal).

Titanium Oxide (Ti_2O_3) O_3Ti_2(cr,l)

VANADIUM OXIDE (V_2O_3) CRYSTAL M_r = 149.8812

$S°(298.15\ K) = 98.067 \pm 1.3\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 168.8 \pm 0.2\ K$
$T_{fus} = 2340 \pm 20\ K$

$\Delta_f H°(0\ K) = -1213.971 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1218.799 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 1.623\ kJ\ mol^{-1}$
$\Delta_{fus} H° = [117.152]\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted enthalpies of formation for the vanadium oxides, and in particular V_2O_3(cr), are based on the combustion studies by Mah and Kelley (1). The adopted value is $\Delta_f H°(V_2O_3, cr, 298.15\ K) = -291.3$ kcal mol^{-1} as reported by Mah and Kelley (1). For more details refer to the V_2O_5(cr) table (2). We assign an uncertainty limit of ±1.5 kcal mol^{-1}.

Charlu and Kleppa (3) reported a enthalpy of formation value of -291.0 ± 0.9 kcal mol^{-1} for V_2O_3 based on oxidation studies to V_2O_5(cr) in a high temperature microcalorimeter. An advantage of this technique is that complete oxidation to V_2O_5(cr) was achieved whereas in the study by Mah and Kelley (1) a mixture of the two oxides V_2O_4 and V_2O_5 was obtained. Other combustion studies have been reported by Siemonsen and Ulich (4) and Vol'f and Ariya (5). Additional enthalpy of formation values may be obtained from the sodium peroxide fusion studies by Mixter (6) and Ruff and Friedrich (7) and the following equilibrium studies involving vanadium and its oxides: H_2O/H_2 by Kobayashi (8), Muller (9), and Karasev, Polyakov and Samarin (10); and CO/CO_2 by Spencer and Justice (11). As an example, the study by Spencer and Justice (11) leads to $\Delta_f H°(298.15\ K) = -287.9$ kcal mol^{-1} for V_2O_3(cr). The analysis, based on data in the range 1024-1169 K, indicates a third law drift of -0.96 ± 0.43 cal K^{-1} mol^{-1}.

Heat Capacity and Entropy

Anderson (12) measured the heat capacity of V_2O_3(cr) in the range 57-287 K. The data indicated an anomaly in the region 165-182 K. These heat capacity data are joined smoothly at 298 K with the high temperature heat capacity values as derived from the enthalpy measurements of Cook (13). The adopted $C_p°$ values are based on these two studies (12, 13). Using the combination of Debye and Einstein functions as suggested by Anderson (12), we calculate S°(50 K) = 0.783 cal K^{-1} mol^{-1} and H°(50;0) = 0.0284 kcal mol^{-1}. There is considerable scatter in the data of Cook (13); the deviations from the adopted values range from -0.8 to 0.6% except for the data point at 369.1 K which is -1.4% low (~25 cal K^{-1} mol^{-1}).

Khlyustov et al. (14) measured the heat capacity of V_2O_3 in the region 120-190 K. For $T < T_{trs}$, this latter study lies above the Anderson data by ~7% while for $T > T_{trs}$, it is 10% higher. Three other studies examined the heat capacity in the range 343-573 K (15, 16, 17). These latter three studies indicated irregularities in the $C_p°$ values in the region of investigation. We do not adopt these works, pending further independent verification.

Phase Data

A review of the literature of the V-O system by Stringer (18) stated that V_2O_3 has a homogeneity range of roughly $VO_{1.44}$ to $VO_{1.65}$. On cooling V_2O_3(cr) through T_{trs}, the crystal undergoes a structural distortion from hexagonal corundum to monoclinic. Numerous references as to the homogeneity range and crystal structure are contained, for example, in the reviews by Stringer (18) and Adler (19) as well as in the x-ray study by Minomura and Nagasaki (20).

Transition Data

The heat capacity data of Anderson (12) indicated an anomaly at 168.8 K. The anomaly appeared similar to a λ-type transition and a smooth curve is easily drawn joining the heat capacity data on either side of the transition. Anderson (12) made five measurements to determine the energy necessary to heat V_2O_3(cr) through the transition. The mean enthalpy of the five measurements from 161.3 to 180.0 K was reported as 692.2 ± 2.4 cal K^{-1} mol^{-1}. Subtracting the calculated base heat in this same region, we calculate $\Delta_{trs}H° = 0.388$ kcal mol^{-1}. We adopt $T_{trs} = 168.8$ K and $\Delta_{trs}H° = 0.388$ kcal mol^{-1}, and consider it to be first order.

Khlyustov et al. (14) reported heat capacity data in the region 123-184 K and reported a transition which resembled a λ-type with a maximum at 165.66 K with $\Delta_{trs}H° = 0.356$ kcal mol^{-1}. Although both heat capacity studies (12, 14) appeared to indicate a second order transition, Minomura and Nagasaki (20) determined through x-ray measurements that V_2O_3(cr) undergoes a discontinuous volume contraction (~3%) at T_{trs}, indicative of a first order transition. Austin (21) and Feinlieb and Paul (22) studied the pressure dependence of T_{trs} and reported $(dT_{trs}/dP)_{trs}$ values. Using the Clausius-Clapeyron equation for a first order transition with Δ_{vap} from Minomura and Nagasaki (20), we calculate $\Delta_{trs}H° = 0.863$ and 1.020 kcal mol^{-1}, respectively. The calorimetric value for $\Delta_{trs}H°$ is more reliable than these latter two determinations. For further information on this transition, the review by Adler (19) is suggested. There are indications of possible transitional behavior above room temperature (15, 16, 17, 19). We adopt only regular behavior above 298.15 K.

Fusion Data

See the liquid table for details.

Sublimation Data

The experimental evidence indicated that, although V_2O_3(cr) sublimes congruently, the vapors do not contain V_2O_3(g) (23).

PREVIOUS: CURRENT: December 1973

$S°(298.15\ K) = [152.250]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2340 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [-1093.054]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [117.152]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(V_2O_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2340 K)-H°(298.15 K), between the crystal and the liquid.

Heat Capacity and Entropy

$C_p°$ for the liquid phase is estimated to be a constant 7.5 cal K^{-1} g-atom^{-1}. Below the assumed glass transition temperature at 1600 K, $C_p°$ is taken from the crystal. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

T_{fus} = 2340 ± 20 K is the value extracted from the V-O phase diagram proposed by Stringer (1). This value is adopted and corrected to IPTS-68. $\Delta_{fus}H°$ is estimated such that $\Delta_{fus}S°$ is 12 cal K^{-1} mol^{-1} as observed (2) for Al_2O_3(α, corundum).

Vaporization Data

There is no evidence as to the existence of V_2O_3(g) and thus we do not report any heat of vaporization. See VO(g) and VO_2(g) tables for more information (2).

TUNGSTEN OXIDE (WO_3) CRYSTAL M_r = 231.8482

$S°(298.15\ K) = 75.912 \pm 1.3\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 1050\ K$
$T_{fus} = 1745\ K$

$\Delta_f H°(0\ K) = -837.259 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -842.909 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 1.485\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 73.429\ kJ\ mol^{-1}$

Enthalpy of Formation

The selected enthalpy of formation, $\Delta_f H°(WO_3, cr, 298.15\ K) = -201.46 \pm 0.2$ kcal mol^{-1}, was determined by Mah (1) using bomb calorimetry. Huff et al. (2) have reviewed the literature enthalpy of formation data and also measured calorimetrically the enthalpy of formation, -201.84 ± 0.1 kcal mol^{-1}, which is in good agreement with the value selected. Other combustion values were reported as $\Delta_f H°(298.15\ K) = -199 \pm 1$ kcal mol^{-1} by Griffis (3); and $\Delta_f H°(298.15\ K) = -205.3$ kcal mol^{-1} by Vasil'eva et al. (4). Griffis (5) also derived the enthalpy of formation, -202.8 ± 1 kcal mol^{-1}, from equilibrium data.

Heat Capacity and Entropy

The low temperature (55-296.7 K) heat capacities and high temperature (399.6 - 1835.8 K) enthalpy data have been measured by King et al. (6), and these data have been used to derive the tabulated heat capacities. Low temperature and high temperature values were joined smoothly at 298.15 K. The entropy was calculated from the heat capacities based on $S°(51\ K) = 1.31$ cal K^{-1} mol^{-1}.

King et al. (6) were apparently unaware of the transition near 593 K which was reported by Perri et al. (7), and they did not take sufficient points in that region for the precise enthalpy curve. We have adopted only one curve through the region because of the insufficiency of the data and also because the heat effects appear to be small or gradual.

Transition and Fusion Data

The enthalpy of transition, the transition point, the enthalpy of melting and the melting point were derived from the high temperature enthalpy data of King et al. (6).

The melting point, 1746 ± 1 K, has also been quoted by Schneider (8).

In the high temperature x-ray diffractometric studies, Perri et al. (7) indicate that WO_3 undergoes a phase transition from monoclinic to orthorhombic at approximately 593 K and from orthorhombic to tetragonal at 993 K.

Sublimation Data

The values of $\Delta_{sub} H°(298.15\ K)$ are calculated as the enthalpy of sublimation of one mole of crystal to one mole of monomer, 1/2 mole of dimer, 1/3 mole of trimer and 1/4 mole of tetramer, respectively.

PREVIOUS: March 1963 CURRENT: September 1966

$S°(298.15\ K) = [103.508]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1745\ K$

$\Delta_f H°(298.15\ K) = [-788.915]\ kJ\ mol^{-1}$

$\Delta_{fus} H° \approx 73.429\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_r H°(\ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1745\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity between the melting point and 1836 K was determined from the enthalpy measurement by King et al. (1). The heat capacity was assumed constant above and below the measured range. At 1000 K, a glass transition was assumed below which the heat capacity was assumed to be that of the crystal. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion and Vaporization Data

The heat and temperature of melting were obtained from King et al. (1).

T_{vap}(to equilibrium vapor) = 2110 K is the temperature at which the total pressure reaches one atm based on the calculated partial pressures of $WO_3(g)$, $W_2O_6(g)$, $W_3O_8(g)$, $W_3O_9(g)$, and $W_4O_{12}(g)$. $\Delta_{vap}H°$(to equilbrium vapor) = 18.3 kcal mol^{-1} at the boiling point is calculated as the enthalpy of vaporization of one mole of the liquid to vapor containing 23.7 mole percent of $W_2O_6(g)$, 0.57 mole percent of $W_3O_8(g)$, 58.2 mole percent of $W_3O_9(g)$ and 17.53 mole percent of $W_4O_{12}(g)$.

Tungsten Oxide (WO_3) O_3W_1(cr,l)

$S°(298.15\ K) = [286.440]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -288.47 \pm 29.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -292.88 \pm 29.3\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
[564](1)	1040 (2)
[347](1)	[320](2)

Ground State Quantum Weight: 1 σ = [6]
Point Group: [D_{3h}]
Bond Distance: W-O = [1.81] Å
Bond Angle: O-W-O = [120]°
Product of the Moments of Inertia: $I_A I_B I_C = [4.4509666 \times 10^{-114}]\ g^3\ cm^6$

Enthalpy of Formation

The Gibbs energy of formation of gaseous tungsten trioxide, $\Delta_f G°(WO_3, g) = -75{,}700 + 15.54\ T\ cal\ K^{-1}\ mol^{-1}$, over the temperature range 1920 - 2020 K has been reported by Ackermann and Thorn (1), using the reaction 3 MgO(cr) + W(cr) + 3 Mg(g) + WO_3(g). 3rd law calculation gives $\Delta_f H°(WO_3, g, 298.15\ K) = -71.3\ kcal\ mol^{-1}$ using JANAF functions. The 2nd law value of $\Delta_f H°(298.15\ K)$ is $-74.8\ kcal\ mol^{-1}$.

DeMaria et al. (2) have reported the partial pressures of WO(g), WO_2(g), WO_3(g) and O(g) in a mass spectrometric study of aluminum oxide vaporized from a tungsten cell from 2188 to 2475 K. 3rd law treatment of their partial pressure data gives $\Delta_r H°(298.15\ K) = -245.2\ kcal\ mol^{-1}$ for W(cr) + 3 O(g) → WO(g) which yields $\Delta_f H°(WO_3, g, 298.15\ K) = -66.5\ kcal\ mol^{-1}$. The 3rd law drift is $21 \pm 7\ cal\ K^{-1}\ mol^{-1}$. Partial pressures of WO_2(g), WO_3(g), and O(g) at 2242 K have also been reported by Chupka et al. (3) in a mass spectrometric study of beryllium oxide in a tungsten cell. Similar calculation gives $\Delta_r H°(WO_3, g, 298.15\ K) = -73.0\ kcal\ mol^{-1}$.

The value, $-70 \pm 7\ kcal\ mol^{-1}$, is selected for the enthalpy of formation at 298.15 K.

Heat Capacity and Entropy

The WO_3(g) was assumed to be a planar D_{3h} molecule with a bond angle O-W-O = 120°. The bond distance W-O was estimated to be the same as that in WO(g). Weltner and McLeod (4) have observed the vibrational frequency of 1040 cm^{-1} in the infrared spectrum by matrix isolation, and also estimated the frequencies 347 and 564 cm^{-1} based on the stretching force constant of WO(g). The estimation of 320 cm^{-1} was obtained from DeMaria et al (2). These frequencies have been adopted in the tabulation. The principal moments of inertia are $I_A = I_B = 13.0559 \times 10^{-39}$ and $I_C = 26.1119 \times 10^{-39}\ g\ cm^2$.

LEAD SILICATE (Pb_2SiO_4) CRYSTAL M_r = 506.4831

$S°(298.15\ K) = 186.832 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1016\ K$

$\Delta_f H°(0\ K) = -1369.466 \pm 14.6\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1377.875 \pm 14.6\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of the reaction 2 PbO(cr) + SiO_2(cr) → Pb_2SiO_4(cr) was reported by Kubaschewski and Evans (1). This value for the enthalpy of reaction of the oxides has been converted to the enthalpy of formation using JANAF auxiliary data (4). The above $\Delta_r H°(298.15\ K) = -7.00 \pm 3.5\ kcal\ mol^{-1}$

Heat Capacity and Entropy

In the low temperature region (53.07-298.15 K) the $C_p°$ values are those determined by King (2). Above 298.15, $C_p°$ values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.07 K using the Debye and Einstein functions D(78.5/T) + 2E(164/T) + 3E(547/T) + E(1379/T) given by King (2). $S°(53.07\ K) = 8.248\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

T_{fus} was taken from Geller et al. (3).

PREVIOUS: CURRENT: June 1965

$S°(298.15\ K) = 211.961 \pm 6.7\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -710.871 \pm 6.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -718.686 \pm 6.2\ kJ\ mol^{-1}$

Enthalpy of Formation

Espada et al. (1) have measured the enthalpy of the reduction reaction $PbO_{1.3}(cr) + 1.3\ H_2(g) \rightarrow Pb(cr) + 1.3\ H_2O(\ell)$ as -32.07 kcal mol^{-1} as -32.07 kcal mol^{-1}. They assumed that the sample consisted of 90.1% mol percent $PbO_{1.333}$ and 9.9 mol PbO and corrected the observed enthalpy of reaction to -33.82 ± 0.25 kcal mol^{-1} for the reaction $PbO_{1.333}(cr) + 1.333\ H_2(g) \rightarrow Pb(cr) + 1.333\ H_2O(\ell)$. This leads to $\Delta_f H°(Pb_3O_4, cr) = -171.77 \pm 1.5$ kcal mol^{-1} which is adopted.

Andrews and Brown (2) used reversible cells to obtain $\Delta_r G°(298.15\ K) = -6940$ cal K^{-1} mol^{-1} for the reaction $Hg(\ell) + Pb_3O_4(cr) \rightarrow HgO(cr) + 3\ PbO(red, cr)$, with JANAF auxiliary data (3) this yields $\Delta_f G°(Pb_3O_4, cr, 298.15\ K) = -142.76 \pm 0.6$ kcal mol^{-1} which is equivalent to $\Delta_f H°(Pb_3O_4, cr, 298.15\ K) = -170.73 \pm 1.1$ kcal mol^{-1}. This value is in agreement with the adopted value within the combined uncertainties.

Reinders and Hamburger (4) and Otto (5) studied the decomposition pressure of the reaction $Pb_3O_4(cr) \rightarrow 3\ PbO(cr) + 0.5\ O_2(g)$ a 2nd and 3rd law analysis of their data is given below.

Source	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(4)	16	718-880	20.19±0.14	19.08±0.17	-1.4±0.2	-175.44
(5)	19	757-911	20.84±0.10	18.98±0.22	-2.2±0.1	-175.34

Although these two sets of data are in good agreement, they are outside the adopted enthalpy of formation uncertainty limits, and realistic adjustments of the entropy or heat capacity fail to eliminate this discrepancy.

In addition there have been cell measurements linking PbO_2 and Pb_3O_4, which serve to indicate the overall consistency of the lead oxygen system. The absolute uncertainty in the enthalpy of formation and the difficulty of preparing pure PbO_2 make it a poor choice on which to base the heat of formation of Pb_3O_4. Andrews and Brown (2) obtained $\Delta_r G°(298.15\ K) = -18.12$ kcal mol^{-1} for the reaction $2\ Hg(\ell) + 3\ PbO_2(cr) \rightarrow Pb_3O_4(cr) + 2\ HgO(cr)$. This yields $\Delta_f G°(Pb_3O_4, cr, 298.15\ K) = -144.62 \pm 2.1$ kcal mol^{-1} with JANAF auxiliary data (3), which corresponds to $\Delta_f H°(Pb_3O_4, cr, 298.15\ K) = -172.59 \pm 2.6$ kcal mol^{-1}. Millar (6) has recalculated the data of Glasstone for the reaction $3\ PbO_2(cr) + 2\ H_2(g) \rightarrow Pb_3O_4 + 2\ H_2O(\ell)$ as $\Delta_r G°(298.15\ K) = -104.36$ kcal mol^{-1} which with auxiliary data (3, 7) yields $\Delta_f G°(Pb_3O_4, cr, 298.15\ K) = -145.45 \pm 2.1$ kcal mol^{-1} which corresponds to $\Delta_f H°(Pb_3O_4, cr, 298.15\ K) = -173.42 \pm 2.6$ kcal mol^{-1}.

Heat Capacity and Entropy

The low temperature enthalpy capacity from 71.5 K to 292.6 K has been reported by Millar (6). These values were used to calculate $S°(298.15\ K)$ based on $S°(70.8\ K) = 12.67$ cal K^{-1} mol^{-1} (7). Enthalpies in the range 365 to 781 K have been reported by Bousquet et al. (8). These data encompass the range where the dissociation pressure is significant (76 mm) and we have not used the data above 600 K. The mean heat capacities were plotted at the mean temperatures for the five points used and a smooth curve was drawn graphically through them and the low temperature data set. The four highest points of Millar (6) were not used since at least two were reported as bad points and they did not fit onto the smooth curve.

Decomposition Data

The decomposition pressure reaches 1 atm at 869.7 according to Reinders and Hamburger (4) and at 867.2 K according to Otto (5). This table indicates a temperature of 690 K for the decomposition pressure to reach 1 atm. The significant difference is due to the fact that heat and entropy derived from the dissociation cannot be simultaneously satisfied by any realistic variation of the entropy and heat capacity of Pb_3O_4.

$S°(298.15\ K) = 110.541 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$T_{trs1}(\alpha + \alpha', proposed) = [540]\ K$

$T_{trs2}(\alpha' + \beta) = 1013 \pm 5\ K$

$\Delta_f H°(0\ K) = -969.934 \pm 0.10\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -980.144 \pm 0.10\ kJ\ mol^{-1}$

$\Delta_{trs1} H°(\alpha + \alpha') = [5.021]\ kJ\ mol^{-1}$

$\Delta_{trs2} H°(\alpha' + \beta) = 20.334 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

Adami and King (1) determined calorimetrically the enthalpies of solution of crystalline ZnO and $ZnSO_4$ in hydrochloric acid solution. From these measurements they derived the enthalpy for the reaction ZnC(cr) + $H_2SO_4 \cdot 7.068\ H_2O(\ell)$ + $ZnSO_4$(cr) + 8.068 $H_2O(\ell)$ as $\Delta_r H°(298.15\ K) = -9.250 \pm 0.080\ kcal\ mol^{-1}$. Combining this result with the enthalpies of formation of ZnO (2), $H_2SO_4 \cdot 7.068\ H_2O$ (3, 4), and H_2O (4), we derive $\Delta_f H°(ZnSO_4, cr, 298.15\ K) -234.26 \pm 0.25\ kcal\ mol^{-1}$ which is the value adopted for this tabulation.

The enthalpy of solution at infinite dilution, $\Delta_{sol} H°(ZnSO_4, cr, 298.15\ K) = -19.9 \pm 0.2\ kcal\ mol^{-1}$ was taken from the work of Larson et al. (5). When this result is combined with enthalpies of formation of the infinitely dilute ions from (4), we obtain $\Delta_f H°(ZnSO_4, aq, \infty, 298.15\ K) = -254.06 \pm 0.14\ kcal\ mol^{-1}$ and $\Delta_f H°(ZnSO_4, cr, 298.15\ K) = -234.16 \pm 0.34\ kcal\ mol^{-1}$.

Ishikawa and Murooka (6) determined $\Delta_r H°(298.15\ K) = -56.330\ kcal\ mol^{-1}$ from cell measurements for the reaction Zn(cr) + Hg_2SO_4(cr) = $ZnSO_4$(cr) + 2 Hg(ℓ) as reported by Kelley (7). When this result is combined with *JANAF auxiliary data for Zn(cr)* (8) and with data from CODATA (9) for Hg(ℓ) and Hg_2SO_4(cr), we obtain $\Delta_f H°(ZnSO_4, cr, 298.15\ K) = -234.01 \pm 1.0\ kcal\ mol^{-1}$.

Heat Capacity and Entropy

Low temperature heat capacities of $ZnSO_4$(cr, α) have been measured by Weller (10) from 51.7 - 296.5 K. A small heat capacity maximum was observed at 124.37 K. Our adopted value of $S°(298.15\ K) = 26.42 \pm 0.3\ cal\ K^{-1}\ mol^{-1}$ obtained from $C_p°$ is based on S°(51 K) = 2.27 cal K^{-1} mol^{-1} obtained by Weller (10) by extrapolation of the measured heat capacity with a combination of Debye and Einstein functions. We have smoothed the data of Weller (10) by fitting the data with orthogonal polynomials over selected overlapping temperature intervals.

High temperature enthalpy data have been measured by Hosmer and Krikorian (11, 510 - 1168 K) as well as by Voskresenskaya and Patsukova (12, 523-806 K), Krestovnikov and Feigina (13, 573-1073 K), and by Chizhikov and Khirik (14, 373-973 K). The enthalpy data of Hosmer and Krikorian (11) is higher than the data of Voskresenskaya and Patsukova (12) or Krestovnikov and Feigina (13). Wet-chemical and x-ray analysis of their sample (11) indicate that the sample was pure zinc sulfate. The lower results of (12) and (13) may be due to decomposition to the oxy-sulfate which can occur in vacuum dehydration (11). We adopt the enthalpy results from Hosmer and Krikorian (11). Problems remain in matching the low temperature heat capacity data to the high temperature enthalpy data (300 - 600 K region). There are at least three possibilities for the mismatch: 1) an unobserved transition occurs between 300-600 K, 2) the data of (10) and (11) are essentially correct but were measured on different materials, or 3) a bias exists in the data from one of the calorimeters. In the absence of other information, we arbitrarily adopt a transition at 540 K with $\Delta_{trs} H° = 1.20\ kcal\ mol^{-1}$. Below 540 K, we adopt heat capacities based on an extrapolation of the work of Weller (10). Above 540 K, we adopt heat capacities based on the enthalpy data of Hosmer and Krikorian (11).

Transition Data

$ZnSO_4$(cr, α) is the low-temperature form of zinc sulfate, also known as the mineral zinkosite and $ZnSO_4$(cr, II). The crystals are orthorhombic, space group D_{2h}^{16} - Pnma (15). The transition to the high-temperature (β-phase) cubic form (space group F43m, 16) occurs at 1013±5 K (15). The heat of transition is based on the drop calorimetry measurement of Hosmer and Krikorian (11) which is in good agreement with the DTA measurement of Ingraham and Marier (17, 4.74 kcal mol^{-1}). Decomposition occurs through an oxy-sulfate intermediate which has the probable composition ZnO · 2 $ZnSO_4$ (11).

Hosmer and Krikorian (11) have also measured enthalpies of the high-temperature $ZnSO_4$(cr, β) phase of zinc sulfate. We adopt their results (1038 - 1168 K), which imply a constant heat capacity, and extrapolate this value to 2000 K.

ZIRCONIUM SILICATE ($ZrSiO_4$) CRYSTAL M_r = 183.3031

$S°(298.15\ K) = 84.026 \pm 1.3\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -2012.774 \pm 2.9\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2023.951 \pm 2.9\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(ZrSiO_4, cr, 298.15\ K)$ was calculated from the $\Delta_r H°(298.15\ K)$ of its constituent oxides $ZrO_2(cr) + SiO(cr) = ZrSiO_4(cr)$ and the $\Delta_f H°(298.15\ K)$ values for $ZrO_2(cr)$ and $SiO_2(cr)$ in JANAF tables (4). The $\Delta_r H°(298.15\ K) = -4.736\ kcal\ mol^{-1}$ was based on the Gibbs energy of formation of its constituent oxides at the decomposition temperature 1811 K.

Heat Capacity and Entropy

At low temperatures, $C_p°$ were used from Kelley (1). From 298-940 K, $C_p°$ was calculated by using the Coughlin and King (2) equation $C_p° = 31.48 + 3.92 \times 10^{-3}T - 8.08 \times 10^5 T^{-2}$ which joined smoothly with the low temperature data. Above 940 K the data were estimated by extending the curve smoothly. The entropy was calculated at 52.7 K using the Debye and Einstein (3) functions $D(321/T) + 2E(407/T) + 2E(796/T) + E(1624/T)$ given by Kelley (2). $S°(52.7\ K) = 0.65404\ cal\ K^{-1}\ mol^{-1}$.

Decomposition Data

T_{dcm} is the temperature at which $\Delta_r G° = 0$ for the reaction $ZrSiO_4(cr) \rightarrow ZrO_2(cr) + SiO_2(cr)$. T_{dcm} = 1811 K was taken from Curtis and Sowman (3).

VANADIUM OXIDE (V_2O_4) CRYSTAL M_r = 165.8806

$S°(298.15\ K) = 103.525 \pm 2.1\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 340 \pm 5\ K$
$T_{fus} = 1818 \pm 15\ K$

$\Delta_f H°(0\ K) = -1418.617 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -1427.162 \pm 6.3\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 8.996 \pm 0.8\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 112.068 \pm 2.5\ kJ\ mol^{-1}$

Enthalpy of Formation

The adopted $\Delta_f H°$ values for the vanadium oxides, and in particular V_2O_4(cr) are based on the combustion studies by Mah and Kelley (1). The adopted value is -341.1 kcal mol^{-1} which was obtained by rounding the reported value of Mah and Kelley (1). For more details refer to the V_2O_5(cr) table (2). Charlu and Kleppa (3) reported a enthalpy of formation value at $\Delta_f H°(298.15\ K)$ = -342.4 ± 0.78 kcal mol^{-1} based on oxidation studies to V_2O_5(cr) in a high temperature microcalorimeter. The combustion by this technique yielded complete oxidation to V_2O_5(cr) as opposed to the method of Mah and Kelley (1), whereby $\Delta_f H°$ for V_2O_4(cr) was determined simultaneously with that for V_2O_5(cr) due to incomplete combustion of V(cr). A combustion study by Siemonsen and Ulich (4) led to the reported value of -342 ± 2 kcal mol^{-1} for $\Delta_f H°(V_2O_4, cr, 293\ K)$. Additional thermodynamic data which relate V_2O_3(cr) with V_2O_4(cr) or V_2O_5(cr) is contained in the sodium oxide fusion studies by Mixter (5), the H_2O-H_2 equilibrium study by Muller (6), the CO-CO_2 equilibrium study by Spencer and Justice (7), and the reduction of V_2O_5(cr) with SO_2 by Flood and Kleppa (8). See V_2O_3(cr) table for some additional information (2).

Heat Capacity and Entropy

Anderson (9) measured the heat capacity of V_2O_4 (reported purity of 99.5% or better) in the range 61.4-279.4 K. Using the combination of Debye and Einstein functions suggested by Anderson (9), we calculate S°(60 K) = 1.48 cal $K^{-1}mol^{-1}$ and H°(60;0) = 63.66 cal K^{-1} mol^{-1}. The data of Anderson (9) show considerable scatter from our adopted values, with a ±2.0% deviation being typical for this data. Cook (10) measured the enthalpy of V_2O_4 in the range 315-1856 K. The enthalpy data for $T < T_{trs}$ appears too high to be fully consistent with $C_p°$ data of Anderson (9). The adopted $C_p°$ values in the region 280-340 K join smoothly with a positive power polynomial fit of the data of Anderson (4) and lead to enthalpy values at 315.5, 322.8, and 323.0 K which are roughly 48, 34, and 39 kcal mol^{-1}, respectively, less than the data of Cook (10). This is a difference of 5-10%. The enthalpy data in the region T_{trs}-T_{fus} are fit to a Kelley type equation and then differentiated to yield our adopted $C_p°$ values. The data of Cook (10) also shows considerable scatter, with deviations ranging from -0.69% to +1.12%.

Three $C_p°$ studies concentrated on the region near T_{trs} but presented only graphical data (11, 12, 13). Kawakubo and Nakagawa (11) reported $C_p°$ values between 30°C and 90°C which are roughly 18% higher than our adopted values below the transition and 25% higher above the transition. Ryder et al. (12) and Chandrashekhar et al. (13) measured $C_p°$ values in the range 40-375 K and 150-730 K. These latter two works agree well graphically in their region of overlap. The $C_p°$ values above T_{trs} are very similar to our adopted values; at 500 K the adopted values are less than 0.1 cal K^{-1} mol^{-1} higher while at 700 K, roughly 0.75 cal K^{-1} mol^{-1} lower. Below T_{trs}, the differences are more substantial; the adopted values lying approximately 1.5 cal K^{-1} mol^{-1} higher.

Phase Data

Minomura and Nagasaki (14) referenced earlier x-ray data and provided additional data to show that V_2O_4 undergoes a structural distortion to lower symmetry on cooling through a transition temperature of 340 K; tetragonal rutile to a monoclinic structure with the unit cell doubling in size. Recent crystallographic investigations by Kawada et al. (15) verified the doubling of the size of the unit cell and also detected considerable distortion of the shape of the unit cell. The literature review on the V-O system by Stringer (16) indicated that there are a series of oxides between V_3O_5 and V_2O_4. These oxides may be considered as members of a homologous series with $V_2O_4(VO_2)$ being the series limit (16). Numerous references on phase data are contained in the reviews by Stringer (16), Adler (17) and Neuberger (18).

Transition Data

Minomura and Nagasaki (14) repored that the structural distortion occurs at 340 K. This value is consistent with the enthalpy data of Cook (10). Kawakubo and Nakagawa (11) measured the temperature dependence of five physical properties through the transition point and concluded that the transition occurs at 338 K. We adopt T_{trs} = 340 + 5 K.

Using our adopted enthalpy values for $T < T_{trs}$ and $T > T_{trs}$, we calculate and adopt $\Delta_{fus} H°$ = 2.15 ± 0.20 kcal mol^{-1}. Ryder et al. (12) reported a value of 2.040 ± 0.010 kcal mol^{-1} and Chandrashekhar et al. (13), a value of 2.24 kcal mol^{-1}. The values of $\Delta_{fus} H°$ = 1.60 and 1.50 kcal mol^{-1} reported by Klemm and Grimm (19) and Kawakubo and Nakagawa (11), respectively, are considered too low. In our tabulation, the transition is treated as being first order. Controversy exists concerning the order of the transition, as discussed by Adler (17). Additional references may be found in Stringer (16), Adler (17) and Neuberger (18).

Fusion Data

See the liquid table for details.

PREVIOUS: June 1973 CURRENT: December 1973

$S°(298.15\ K)$ = [173.473] J K^{-1} mol^{-1}

T_{fus} = 1818 ± 15 K

$\Delta_f H°(298.15\ K)$ = [-1332.151] kJ mol^{-1}

$\Delta_{fus}H°$ = 112.068 ± 2.5 kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(V_2O_4, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1818 K)-H°(298.15 K), between V_2O_4(cr) and $V_2O_4(\ell)$.

Heat Capacity and Entropy

Cook (1) measured the enthalpy of $V_2O_4(\ell)$ in the region 1829.7-1856.8 K and represented the data by the equation H°(T)-H°(298.15 K) = 51.00 T-5910 cal K^{-1} mol^{-1}. Thus $C_p°$ for the liquid is adopted as 51.00 cal K^{-1} mol^{-1}. Since the enthalpy measurements only cover a range of 39 K in the liquid region, the value of $C_p°$ should not be viewed as a precise value. A glass transition is assumed at 1200 K. Below 1200 K, the $C_p°$ values are those of the crystal with the exception that the values of $C_p°$ between 298 and 340 K are a smooth extrapolation of the crystal values above T_{trs}. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

The melting point of V_2O_4(cr) is adopted as 1818 K, based on the enthalpy data of Cook (1). The enthalpy of melting is calculated from the difference in H°(1818 K)-H°(298.15 K) for $V_2O_4(\ell)$ and V_2O_4(cr).

(8)	99.80		-487.7±0.9
(9)	99.16, 99.7	99.5 -99.9	-489.3±0.4
(10)			-480.0±0.8

*Refers to extent of reaction 2 Ta(cr) + 5/2 O_2(g) = Ta_2O_5(cr)
**The reported value of -488.8±0.5 was corrected by Huber et al. (8) in order to have the value based on the current atomic weight of Ta.

The value chosen for $\Delta_f H°(Ta_2O_5$, cr, 298.15 K) is -489.0 ± 0.5 based primarily on the work by Humphrey (7) and Kornilov et al. (9). Worrell (17), using a high temperature galvanic cell, obtained $\Delta_f G°$ values of Ta_2O_5 in the range 1050-1300 K which are approximately 0.6-1.1 kcal mol^{-1} more negative than the values tabulated here. Ignatowicz and Davies (12) using a galvanic cell approach reported $\Delta_f G°$ values for Ta_2O_5 in the range 1073-1373 K. Barbi (11, 13) determined $\Delta_f G°$ based on emf measurements in the range 1079-1776 K while Rezukhina and Kravchenko (16) worked in the range 1200-1350 K. A third law analysis of the reported smoothed results yields the following.

Source	$\Delta_f H°(298.15\ K)$, kcal mol^{-1}	Drift cal K^{-1} mol^{-1}
(11)	-484.8	0.85
(12)	-487.9	-0.65
(13)*	-484.7	+0.95
(16)	-487.9	+0.83

*Actual experimental data was analyzed.

These latter three works (12, 13, 16) did not specify purity of sample or the state of polymorphism.

Based on the recent critical review by Reisman and Holtzberg (1), this discussion has been concerned with the low temperature β-phase of Ta_2O_5. Even though two $\Delta_f H°(298.15\ K)$ studies (9, 10) apparently deal with the high temperature α-phase, there does not appear to be any difference in the $\Delta_f H°(298.15\ K)$ values for the α-phase or β-phase, within experimental error (1).

Heat Capacity and Entropy

Kelley (14) measured the heat capacity of Ta_2O_5(cr) from 53.4 K to 294.2 K and fitted the data (29 data points) with a combination of Debye and Einstein functions. These functions were used to calculate $S°(50\ K) = 2.47$ cal K^{-1} mol^{-1}. Orr (15) measured the enthalpy of Ta_2O_5(cr) from 395.6 K to 1802.6 K (15 data points). Nine data points at the high temperature end of the Kelley data were fitted by a four term polynomial, and integrated to yield enthalpy values in the vicinity of 298.15 K. These enthalpy values were combined with the Orr data, fitted to a six term polynomial, and extrapolated to 2800 K. The complete Kelley data was also fitted by a six term polynomial. The Nb_2O_5 heat capacity and enthalpy data presented in these tables are treated in the same manner so as to maintain consistency between the results for Nb_2O_5 and Ta_2O_5.

The Ta_2O_5(cr) sample used by Kelley (14) and Orr (15) was the same. Presumably both were using the low temperature β-phase of Ta_2O_5, as discussed by Reisman and Holtzberg (1) and Orr (15). The enthalpy data of Orr (15) did not conclusively indicate any phase transitions, i.e., the β → α transition, in the vicinity of 1633 K, as reported by Reisman and Holtzberg (1).

Fusion Data

See the liquid table for details.

PREVIOUS: CURRENT: December 1972

TANTALUM OXIDE (Ta_2O_5) LIQUID M_r = 441.89128

$S°(298.15\ K)$ = [183.050] J K^{-1} mol^{-1}

T_{fus} = 2058 ± 30 K

$\Delta_f H°(298.15\ K)$ = [-1957.171] kJ mol^{-1}

$\Delta_{fus} H°$ = [120.081 ± 16.7] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Ta_2O_5, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2058 K)-H°(298.15 K), between Ta_2O_5(cr) and $Ta_2O_5(\ell)$.

Heat Capacity and Entropy

The heat capacity for $Ta_2O_5(\ell)$ is estimated to be 58.00 cal K^{-1} mol^{-1} by analogy with $Nb_2O_5(\ell)$. A glass transition temperature is assumed at 1400 K. The heat capacity values used below 1400 K are those of Ta_2O_5(cr). The entropy at 298.15 K is calculated in a manner analogous to that used in calculating the enthalpy of formation.

Fusion Data

The melting point of β-Ta_2O_5 is chosen as 2058 ± 30 K based on work by Reisman et al. (1). The melting point data and the Ta_2O_5 polymorphism are discussed by Reisman and Holtzberg (2). The heat of fusion, $\Delta_{fus}H°$, is estimated from the entropy of fusion for Nb_2O_5 as reported in these tables. Using the Nb_2O_5 entropy of fusion value of 24.92 cal K^{-1} mol^{-1} and a melting temperature of 2058 K, the enthalpy of fusion for Ta_2O_5 is calculated to be 28.7 ± 4 kcal mol^{-1}.

TITANIUM OXIDE, ALPHA (α-Ti_3O_5) CRYSTAL M_r = 223.6370

$S°(298.15\ K) = 129.369 \pm 1.7\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha + \beta) = 450 \pm 20\ K$

$\Delta_f H°(0\ K) = -2446.057\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2459.146 \pm 4.2\ kJ\ mol^{-1}$

$\Delta_{trs} H° = [13.263 \pm 5.0]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K) = -587.75\ kcal\ mol^{-1}$ is calculated from that of TiO_2(rutile) using $\Delta_c H° = -89.65 \pm 0.05\ kcal\ mol^{-1}$ determined by Humphrey (1) from combustion calorimetry. Ariya et al. (2) reported $\Delta_f H° = -587.0 \pm 1.0\ kcal\ mol^{-1}$ derived from their own values of $\Delta_c H°$ for $Ti_3O_{5.03}$ and Ti(cr). Tests for incomplete combustion were made by grinding the product and igniting it to constant weight in air (1) or in moist oxygen (2). Humphrey (1) reported that his rutile was bright yellow in color and did not gain weight. This implies an atomic ratio (O/Ti) $\geq$ 2.00, compared with the value of ~1.95 reported by Ariya et al. (2). New high-temperature calorimetry by Charlu et al. (9) gave $\Delta_c H°(1100) = -93.57 \pm 1.3\ kcal\ mol^{-1}$ after linear correction to (O/Ti) = 2.00 from 1.97 produced by combustion. Our reduction to 298 K and $Ti_3O_5(\alpha)$ yields $\Delta_c H° = -90.36 \pm 2.5\ kcal\ mol^{-1}$, including an assumed uncertainty allowance of 1% for the weight gains.

The calorimetric data are compared below with new high-temperature data for $\Delta_r G°$ (3, 4). Emf data (4) for reaction B are consistent with the adopted $\Delta_f H°$, but integrated values of $\Delta_r G°$ for reaction A yield $\Delta_f H°$ more negative by 1.8 kcal mol^{-1}. Perhaps coincidentally, the $\Delta_c H°$ of Ariya et al. (2) yields $\Delta_f H°$ more negative by 1.9 kcal mol^{-1} when combined with the JANAF $\Delta_f H°$ (5) for TiO_2(rutile). Merritt et al. (3) obtained $\Delta_r G°$ for the combustion reaction A by integrating extensive data for equilibrium oxygen potentials of the many stable phases and solid solutions between TiO_2 and Ti_3O_5. They determined the oxide composition by mass during equilibration with ($H_2 + H_2O$) gas mixtures of known oxygen potential. Gross hysteresis was observed in three regions of composition. Oxygen potentials in these regions were deduced with a reasonable assumption, combined with Zador's emf data for oxygen-deficient rutile, and integrated to yield $\Delta_r G°(1304\ K) = -56.14 \pm 0.43\ kcal\ mol^{-1}$ for reaction A. We obtain $\Delta_r G° = -57.30\ kcal\ mol^{-1}$ at 1273 K and -51.15 at 1473 K by similar integrations of oxygen potentials derived from emf data relative to Fe/FeO and Cr/Cr_2O_3 reported by Suzuki and Sambongi (4).

Suzuki and Sambongi (4) also reported solid-state emf data which relate Ti_3O_5 to Ti_2O_3. We convert their (graphical) emf data (4) to oxygen potentials using the authors' self-consistent data for the reference couples. The results for reaction B yield $\Delta_r H°$ and $\Delta_r S°$ values consistent with our adopted tables. 3rd law values of $\Delta_r H°(298.15\ K)$ of -42.29, -42.15 and -42.13 kcal mol^{-1} agree with -42.52 (1), -42.8 ± 1.3 (2) and -42.0 (9) which can be calculated from combustion calorimetry.

The discrepancy in reaction A may be due to undetected bias (2% too small in magnitude) in $\Delta_r G°$, but alternative possibilities include bias in S° (see Ti_3O_5, β), $\Delta_c H°$ or enthalpy (see TiO_2, rutile).

[b]$\Delta_r G°$ from integration of $\Delta_r \bar{G}(O_2)$ assuming negligible homogeneity range for Ti_2O_3. Alternative $\Delta_r G°$, assuming a linear variation of $\Delta_f \bar{G}°(O_2)$ for $1.42 < x < 1.56$, changes δS by ~0.2 and $\Delta_r H°$ and $\Delta_f H°$ by ~-0.3.

Heat Capacity and Entropy

$C_p°$ below 300 K is based on data of Shomate (6, 53-297 K) and his Debye-Einstein extrapolation to absolute zero. The entropy is calculated by polynomial integration of $C_p°$ based on S°(50 K) = 0.87 cal K^{-1} mol^{-1}. Our assigned entropy uncertainty of ±0.4 cal K^{-1} mol^{-1} includes an additional contribution because the sample gave weak, fuzzy x-ray lines and was only 99.1% pure. Apparently there are new $C_p°$ data (12-300 K) which are unpublished and not yet available (10). $C_p°$ is extrapolated smoothly from 300 K to 450 K and to higher temperatures where $Ti_3O_5(\beta)$ is the stable form. Our extrapolation probably represents the lower limit for the true $C_p°$ below T_{trs}, while the curve of Furukawa and Reilly (7) is an upper limit. The equations reported by Naylor (8) yield even higher enthalpies and fail to join properly with the low temperature data at 298 K. This is due to complications in the enthalpy data (see below) and to positive bias in the drop calorimeter in this temperature range (5).

Naylor (8) measured enthalpy data (326-1340 K) which revealed a transition at ~450 K. When the samples were heated above this temperature, they did not return to the original state on cooling. Enthalpies were then systematically higher by up to 10%. The change in the enthalpy curve seemed to depend on both the temperature and time of heating above T_{trs}. Regrinding was the only method found for returning the sample to its original state. X-ray diffraction at room temperature revealed no difference between these two states, but failure to detect a difference may be due to the weak, fuzzy x-ray lines (6, 8). Possible explanations for the anomalous enthalpy data are noted in Transition Data.

Transition Data

PREVIOUS: March 1967 CURRENT: December 1973

$S°(298.15\ K) = [157.617]\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha \rightarrow \beta) = 450 \pm 20\ K$

$T_{fus} = 2050 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [-2446.189]\ kJ\ mol^{-1}$

$\Delta_{trs} H°[13.263 \pm 5.0]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [171.544]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of $Ti_3O_5(\alpha)$ by adding $\Delta_{trs}H°$ to the difference in H°(450 K)-H°(298.15 K) between the α- and β-phases. Experimental data for $\Delta_r G°$ of the β-phase are analyzed on the table for the α-phase.

Heat Capacity and Entropy

$C_p°$ of the β-phase is derived from fitting of enthalpy data of Naylor (1, 504-1340 K) and Slyusar et al. (2, 580-1994 K). Naylor's data below 482 K are omitted due to thermal hysteresis in the transition; even the points near 500 K show unusual scatter. The new data of Slyusar et al. (2) are suspect due to a discontinuity of almost 4% at ~1250 K where the authors switched container materials and temperature sensors. Their data (2) for Ti_2O_3 and TiO_2(rutile) show similar discontinuities and appear to have a bias of about -4% below 1100 K. Their data for Ti_3O_5 do not differ significantly from those of Naylor (1), so we combine the two sets.

S° is calculated in a manner analogous to that of $\Delta_f H°$. The uncertainty in S° may be as large as ±2.6 cal K^{-1} mol^{-1} due to uncertainty in $\Delta_{trs}H°$, if significant fractions of the β-phase failed to revert to the α-phase during drop calorimetry (1, 2). Naylor's data (1) suggest that this may be the case, but Slyusar et al. (2) make no mention of the problem (see Transition Data). Excluding this possible uncertainty, we estimate that S° of $Ti_3O_5(\beta)$ is uncertain by ±0.6 cal K^{-1} mol^{-1}.

Transition Data and Phase Data

Ti_3O_5 has been identified in three crystalline structures. Low-temperature α-Ti_3O_5 is monoclinic (3), high-temperature β-Ti_3O_5 is a pseudobrookite type with slight monoclinic distortion (3) and metastable γ-Ti_3O_5 (4) is analogous to V_3O_5 (3, 4). Based on its similarity to V_3O_5, γ is the lowest member of the homologous series of phases Ti_nO_{2n-1} with structures related to rutile (9, 10). The magnetic anomaly, observed near 250 K in γ-Ti_3O_5 (4), corresponds to those observed at lower temperatures in Ti_4O_7 and higher homologues. We give the subsequent phase observations because they may have bearing on the anomalous enthalpy data and the discrepancy in $\Delta_f G°$ at high temperatures.

Our designations for the stable phases α and β are reversed from those of Asbrink et al. (4). These phases were called M-type (our α), D-type and D'-type (our β) by Iwasaki et al. (11). D- and D'-types differed only in their low-temperature oxidation products; D-type gave rutile, while D'-type gave mixtures of anatase and rutile (11). D-type was obtained by H_2-reduction of anatase and D'-type by action of H_2 on rutile and Ti or CO on either anatase or rutile. D-type presumably is metastable; Iwasaki et al. (11) postulated free energy diagrams to explain conversion of D-type to other forms. The observations also can be explained be assuming that conversion of D-type is hindered kinetically, like TiO_2(anatase) $\rightarrow$ TiO_2(rutile), until gradually activated at elevated temperature. X-ray patterns of D-type, though not well defined, were similar to those of D'-type (11). Thus, D-type is not the Ti_nO_{2n-1} homologue (γ-Ti_3O_5), as postulated (11) on the basis of oxidation behavior. D- and D'-types may have the same crystal structure but differ in degree of ordering or content of impurities.

Enthalpy data of Naylor (1) gave T_{trs} ~450 K for $\alpha \rightarrow \beta$. X-ray diffraction (4-6), DTA (5), magnetic susceptibility (4, 6), and electrical conductivity (5) confirm the transition temperature. The transition is reversible (3, 5-7) but exhibits thermal hysteresis of about ±20° (5, 6). More important to interpretation of enthalpy measurements is the observation that the β-phase is stabilized (5, 3) at room temperature by small amounts of impurities such as Fe, W and Mg. Samples doped with 5% Fe did not transform; those with 2% Fe gave a much-reduced endotherm (DTA) at ~75° below the normal T_{trs} (5). Accidental contamination by W stabilized the β-form (5).

$\Delta_{trs}H° = 3.17$ kcal mol^{-1} is calculated at T_{trs} from the difference in enthalpy between our β-phase curve fit and our adopted α-phase. Alternative enthalpy curves (8) gave $\Delta_{trs}H° = 2.48$ kcal mol^{-1}. These calculations assume that the β-phase reverted completely to α-phase at room temperature during drop calorimetry (1, 2). Naylor's anomalous enthalpies (1) for the α-phase suggest that part of his sample may have been stabilized in the β-form due to impurities. Other metastable phases may have been present. If the drop-calorimetric samples did not revert completely to α-phase, the true value of $\Delta_{trs}H°$ should be larger than the value calculated on the assumption of complete reversion. $\Delta_r G°$ data (see Ti_3O_5, α) tend to favor an entropy greater than or equal to the adopted value, but DTA data (5) gave $\Delta_{trs}H° = 1.6 \pm 0.4$ kcal mol^{-1}, opposite to the expected direction. We emphasize this unsatisfactory situation by placing $\Delta_{trs}H°$ in brackets and assigning an uncertainty of ±1.2 kcal mol^{-1}. The seeming contradictions should be resolved easily by study of a well-characterized sample in an adiabatic calorimeter or an accurate differential-scanning calorimeter.

Fusion Data and Sublimation Data

See the liquid table for details.

TITANIUM OXIDE (Ti_3O_5) LIQUID M_r = 223.6370

$S°(298.15\ K) = [232.446]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [-2289.059]\ kJ\ mol^{-1}$

$T_{fus} = 2050 \pm 20\ K$ $\Delta_{fus}H° = [171.544]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Ti_3O_5, \ell, 298.15\ K)$ is calculated from that of $Ti_3O_5(\beta)$ by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(2050 K)-H°(298.15 K), between the β-phase and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated as 8 cal K^{-1} g-atom^{-1}. Below the assumed glass transition at 1400 K, $C_p°$ is taken to be the same as that of $Ti_3O_5(\beta)$. S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°$.

Fusion Data

$Ti_3O_5(\beta)$ melts incongruently at 2047 ± 10 K according to Wahlbeck and Gilles (1). Their phase diagram (1) suggests that melting starts at 2047 K and completes near 2077 K. The latter value is close to the melting point of 2083 K reported by Slyusar et al. (2), but is almost 90° above the value of ~1990 which may be interpolated from the liquidus curve of Brauer and Littke (3) for the Ti-O system. Conversion of the value of Wahlbeck and Gilles (1) to IPTS-68 yields 2050 K, which is adopted.

Sublimation and Vaporization Data

$Ti_3O_5(\beta)$ is the congruently vaporizing crystalline phase in the Ti-O system according to the studies of Gilles and coworkers (4-6). Studies of liquid samples (7) showed that the congruently vaporizing composition is between Ti_3O_5 and Ti_4O_7. The principal reaction (4) in congruent vaporization is $Ti_3O_5 \rightarrow TiO(g) + 2\ TiO_2(g)$.

PREVIOUS: CURRENT: December 1973

VANADIUM OXIDE (V_2O_5) CRYSTAL M_r = 181.8800

$S°(298.15\ K) = 130.549 \pm 2.1\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 943 \pm 10\ K$

$\Delta_f H°(0\ K) = -1541.109 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -1550.590 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 64.517 \pm 3.14\ kJ\ mol^{-1}$

Enthalpy of Formation

A review (1) of early experimental studies led to a value of -373 kcal mol^{-1} for $\Delta_f H°(V_2O_5, cr, 298.15\ K)$. More recent combustion studies on V(cr) have led to the following $\Delta_f H°(298.15\ K)$ values for $V_2O_5(cr)$.

Source	Year	$\Delta_f H°(V_2O_5, cr, 298.15\ K)$, kcal mol^{-1}
(2)	1969	-376 ± 2
(3)	1960	-370 ± 1
(4)	1961	-370.6 ± 0.5
(5)	1963	-371.9 ± 1.0

We adopt -370.6 ± 1 kcal mol^{-1} as the enthalpy of formation of $V_2O_5(cr)$ at 298.15 K. This value is the Mah and Kelley result (4) but it is also in good agreement with the results of Golutvin and Kozlovskaya (3) and Volkova and Gel'd (5). The same value was recently adopted by NBS (6).

The combustion of vanadium and its oxides, as reported by Mah and Kelley (4), led to two problems: (1) the oxide products liquefy before the pentoxide composition is obtained and (2) the oxide products are corrosive and cause a container problem. The combustion of vanadium led to varying mixtures of V_2O_4(rutile) and V_2O_5. This was verified by x-ray diffraction. The enthalpy of formation values for V_2O_4 and V_2O_5 were derived from the same set of experiments (4).

Heat Capacity and Entropy

Using a V_2O_5 sample with a reported purity of 99.5% or better, Anderson (7) measured the heat capacity in the range 56.8-289.5 K. Using the combination of Debye and Einstein functions suggested by Anderson (7), we calculate S°(60 K) = 2.81 cal K^{-1} mol^{-1} and H°(60 K)-H°(0 K) = 130.59 cal mol^{-1}. Cook (8) measured the enthalpy of V_2O_5 in the range 372-1513 K. The enthalpy data are fit to a Kelley type equation with the constraint that the data join smoothly with a portion of the integrated data of Anderson (7). The enthalpy data appear to lie too high in comparison with the integrated data of Anderson (7). A better fit is obtained by neglecting the 289.5 data point of Anderson. The Anderson data show considerable scatter and deviate from our adopted $C_p°$ values by ±4% below 65 K and ±1.8% between 65 and 280 K. The 289.5 K data point is 2.7% lower than the adopted value. The Cook data deviates from the adopted enthalpy values by roughly 8% (200 cal mol^{-1}) at 371.6 K with the difference decreasing to 2 cal K^{-1} mol^{-1} at 754.4 K. In the range 771.1-921.1 K the enthalpy difference ranges from -121 to +139 cal K^{-1} mol^{-1}.

Fusion Data

The melting point of V_2O_5 is adopted as T_{fus} = 943 ± 10 K as derived from the enthalpy studies of Cook (8). The heat of melting is calculated to be $\Delta_{fus}H°$ = 15.42 ± 0.75 kcal mol^{-1} based on our analyses of Cook's enthalpy data. Refer to the heat capacity discussion for $V_2O_5(cr)$ and $V_2O_5(\ell)$ for details. By way of comparison, Kohlmuller and Leitner (9) reported T_{fus} = 937.9 K and $\Delta_{fus}H°$ = 14.5 kcal mol^{-1} while Pantony and Vasu (10) reported T_{fus} = 951.12 K and $\Delta_{fus}H°$ = 13.8 kcal mol^{-1}. The latter two studies (9, 10) involved cryoscopic techniques. Murphy and West (11) reported T_{fus} = 943 K based on DTA measurements and Holtzberg et al. (12) determined T_{fus} = 947 ± 5 K in their study of the phases in the K_2O-V_2O_5 system.

The variance in the reported T_{fus} values is probably attributable to the presence of $V_2O_4(cr)$. Refer to the discussion in the section on Sublimation Data in the $V_2O_5(cr)$ table and Decomposition Data in the $V_2O_5(\ell)$ table.

Sublimation Data

Using the combination of Knudsen effusion and mass spectrometric techniques, Berkowitz et al. (13) concluded that $V_2O_5(cr)$ did not "vaporize" invariantly. The temperature range investigated was not reported. Their conclusion was based on two observations: (1) some reduced vanadium oxide species were present in the gas phase, and (2) oxygen was also found to be effusing from the Knudsen cell. Chizhikov et al. (14) studied the dissociation of V_2O_5 at temperatures below T_{fus} using mass spectrometry. They assumed reduced vanadium oxides, in addition to V_4O_{10}, were present in the vapor upon dissociation of $V_2O_5(cr)$ in vacuum. We conclude that there is no invariant sublimation process for $V_2O_5(cr)$ and thus we do not calculate a $\Delta_{sub}H°(298.15\ K)$ value. For related discussion refer to $V_2O_5(\ell)$ table.

PREVIOUS: CURRENT: June 1973

$S°(298.15\ K) = [191.956]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 943 \pm 10\ K$

$T_{dcm} = 1963\ K$

$\Delta_f H°(298.15\ K) = [-1491.209]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 64.517 \pm 3.14\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(V_2O_5, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(943\ K) - H°(298.15\ K)$, between $V_2O_5(cr)$ and $V_2O_5(\ell)$.

Heat Capacity and Entropy

Cook (1) measured the enthalpy of V_2O_5 in the range 372-1513 K. In the liquid region (T > 943 K), Cook (1) represented his data by a straight line with a slope of $C_p° = 45.60\ cal\ K^{-1}\ mol^{-1}$. We adopt this value of $V_2O_5(\ell)$. A glass transition is assumed at 600 K. The heat capacity values used below 600 K are those of $V_2O_5(cr)$. The entropy at 298.15 K is calculated in a manner analogous to that used in calculating the enthalpy of formation.

Decomposition Data

Polyakov (2) measured the weight loss of molten V_2O_5 in the range 700-1200°C for various oxygen flows. The oxygen pressure was greater than the dissociation pressure of V_2O_5. The vapor pressure was calculated by extrapolating to zero oxygen flow and assuming the vapor was monomeric $V_2O_5(g)$. Polyakov (2) assumed no loss of oxygen. Pak (3) proposed a method of calculating vapor pressures from experimental results obtained by the entrainment method with allowance for diffusion. Using Polystov's data and assuming that the vapor phase is the dimeric molecule $V_4O_{10}(g)$, Pak (3) calculated a heat of vaporization $\Delta_{vap}H°(298.15\ K)$ which is 1.4 kcal mol^{-1} more positive than Polyakov's reported value of 32.3 kcal mol^{-1} V_2O_5. Semenov et al. (4) determined the vapor pressure of $V_4O_{10}(g)$ over $V_2O_5(\ell)$ at 1215-1530 K by an improved transfer technique in an oxygen carrier stream. The reported heat of vaporization was calculated to be 3.5 kcal mol^{-1} more positive than Polyakov's value.

Pantony and Vasu (5) stated that molten V_2O_5 attains a constant weight under fixed oxygen pressure and temperature in a reasonably short length of time while in pure nitrogen it is converted into $V_2O_4(cr)$. Pantony and Vasu (5) studied gravimetrically the dissociation equilibrium of $V_2O_5(\ell)$ and confirmed its existence by cryoscopic methods. They concluded that the vapor pressure ascribed to $V_2O_5(g)$ or $V_4O_{10}(g)$ and measured by a transpiration-weight loss method is due to the loss of oxygen arising from the following dissociation $V_2O_5(soln) = V_2O_4(soln) + 1/2\ O_2(g)$.

An effusion-mass spectrometric investigation of the vapor in equilibrium with V_2O_5 in the range 1000-1200 K led Farber et al. (6) to the conclusion that the vapor contained not only $V_4O_{10}(g)$, significant amounts of $V_4O_8(g)$, but also other vanadium oxides. We conclude that there is decomposition upon heating $V_2O_5(\ell)$ in an inert atmosphere or in vacuo. The use of an oxygen atmosphere suppresses decomposition but in the transpiration-weight loss experiment it has not been verified that the weight loss is indeed $V_4O_{10}(g)$. We calculate a decomposition temperature, T_{dcm}, as that temperature at which the free energy approaches zero for the reaction $V_2O_5(\ell) = V_2O_4(\ell) + 1/2\ O_2(g)$.

Vanadium Oxide (V_2O_5) O_5V_2(cr,l)

$S°(298.15\ K) = 345.641 \pm 33.5\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -2189.97 \pm 3.35\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -2214.31 \pm 33.5\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}
613 (1)	465 (2)
613 (1)	643 (3)
302 (3)	919 (3)
370 (3)	1029 (3)
407 (3)	636 (3)

Ground State Quantum Weight: 1 $\sigma = 12$

Point Group: T_d

Bond Distances: P-O = 1.65 ± 0.02 Å

Bond Angles: P-O-P = 127.5 ± 1.0° O-P-O = 99° ± 1°

Product of the Moments of Inertia: $I_A I_B I_C = 4.838017 \times 10^{-112}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(P_4O_6, \ell, 298.15\ K)$ was measured by Koerner and Daniels (1). The measurement was made by burning samples of red phosphorus in nitric oxide in a flow calorimeter. Calculation of the enthalpy of formation of the gas was made using $\Delta_{vap}H°(298.15\ K) = 11.46\ kcal\ mol^{-1}$ as reported by Farr (2).

Heat Capacity and Entropy

The vibrational levels are from the Raman data of Gerding et al. (3) and infrared spectra data of Sidorov and Sobolev (4). Bond distances and angles are from electron diffraction data by Hampson and Stosick (5).

[172] (6)

Ground State Quantum Weight: [1] σ = [4]
Point Group: [D_{2h}]
Bond Distance: W-O = [1.81] Å
Bond Angles: O-W-O = [109.47]° W-O_{bridge}-W = [70.53]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [5.918184 x 10^{-112}] $g^3\ cm^6$

Enthalpy of Formation

The adopted value, $\Delta_f H°(W_2O_6, g, 298.15\ K) = -278.2\ kcal\ mol^{-1}$, was reduced from $\Delta_f H°(1450\ K) = -272.5\ kcal\ mol^{-1}$, reported by Ackermann and Rauh (1). They have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600 K by mass spectrometry, mass effusion, and X-ray diffraction, and also have determined $\Delta_f G°(W_2O_6, g) = 272{,}500 + 54.98T\ cal\ K^{-1}\ mol^{-1}$ from partial pressure measurements over the W-WO_2(cr) system.

Battles (2) has also studied the same system in the temperature range from 1418 to 1527 K. Third law calculation of the partial pressure data gives $\Delta_r H°(298.15\ K) = 144.0\ kcal\ mol^{-1}$ for 3 $WO_2(cr) = W_2O_6(g) + W(cr)$ which yields $\Delta_f H°(W_2O_6, g, 298.15\ K) = -278.8\ kcal\ mol^{-1}$ using all JANAF functions. This value is in good agreement with the value adopted.

Norman and Staley (3) have obtained $\Delta_r H°(1800\ K) = -127\ kcal\ mol^{-1}$ for 2 $WO_3(g) = W_2O_6(g)$ by mass spectrometric study of the vapor over WO_3 dissolved in $CaO-Al_2O_3-SiO_2$. The value of $\Delta_r H°$ was determined by the 2nd law method from ion intensities and leads to $\Delta_f H°(W_2O_6, g, 298.15\ K) = -275\ kcal\ mol^{-1}$, using all JANAF functions (dated Sept. 30, 1966). The absolute pressure values reported by Norman and Staley appear to be quite inconsistent with the JANAF functions since they lead to $\Delta_f H°(W_2O_6, g, 298.15\ K) = -246\ kcal\ mol^{-1}$ by the 3rd law method.

*3rd law value adopted in calculation **2nd law value adopted in calculation

Heat Capacity and Entropy

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 600 cm^{-1} (4), 300 cm^{-1} (8), and 172 cm^{-1} (6) in order to give the entropy at 1450 K, $S°(1450\ K) = 164.66\ cal\ K^{-1}\ mol^{-1}$, corresponding to $\Delta_f S°(1450\ K) = 54.98\ cal\ K^{-1}\ mol^{-1}$ which was reported by Ackermann and Rauh (1). The adopted value, $S°(W_2O_6, g, 298.15\ K) = 99.3\ cal\ K^{-1}\ mol^{-1}$, was reduced from the entropy at 1450 K, using JANAF functions. Second law calculation of the partial pressure data of Battles gives $\Delta_f S°(1470\ K) = 63.5\ cal\ K^{-1}\ mol^{-1}$ for 3 $WO_2(cr) = W_2O_6(g) + W(cr)$. This yields $S°(W_2O_6, g, 298.15\ K) = 97.9\ cal\ K^{-1}\ mol^{-1}$.

The molecular configuration for $W_2O_6(g)$ was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and two of these tetrahedra share a common oxygen edge to form a planar four-member ring. The bond distance W-O was estimated as 1.81 Å and the bond angle O-W-O = 109.47° and W-O_{bridge}-W = 70.53°. The principal moments of inertia are: I_A = 34.8158 x 10^{-39}, I_B = 124.7049 x 10^{-39}, and I_C = 136.3101 x 10^{-39} $g\ cm^2$.

$T_{trs2} = 150 \pm 3\ K$

$T_{fus} = 1950 \pm 20\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -3404.521 \pm 6.3\ kJ\ mol^{-1}$

$\Delta_{trs1} H° = 95 \pm 5\ kJ\ mol^{-1}$

$\Delta_{trs2} H° = 468 \pm 5\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [225.936]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$ is calculated from that of $Ti_3O_5(\beta)$ using $\Delta_r H°(298.15\ K) = -34.16\ kcal\ mol^{-1}$ for $4/3\ Ti_3O_5(\beta) + 1/6\ O_2(g) + Ti_4O_7(cr)$. $\Delta_r H°$ is derived by the 3rd law method from two concordant studies (1, 2) of high-temperature equilibria. Merritt et al. (1) obtained isothermal gravimetric equilibrium over the two-phase system Ti_3O_5-Ti_4O_7 using ($H_2 + H_2O$) gas mixtures of known oxygen potential. Integration yields $\Delta_r G°(1304\ K) = -20.29 \pm 0.16\ kcal\ mol^{-1}$. Suzuki and Sambongi (2) reported solid-state emf data relative to the couple Cr/Cr_2O_3 over a range of ~500°. We convert their (graphical) emf data (2) to oxygen potentials, using the authors' self-consistent data for Cr/Cr_2O_3, and integrate to get $\Delta_r G°$. Vasil'eva and Shaulova (3) reported an equation for the oxygen potential based on their emf data relative to $Fe/Fe_{0.95}O$ over a range of ~90°. Equilibration data of Porter (4) are not considered because of the likelihood of oxidation during quenching of the composition (1).

3rd law analyses of the equilibria for $4/3\ Ti_3O_5(\beta) + 1/6\ O_2(g) + Ti_4O_7(cr)$ are summarized below. Merritt et al. (1) agree closely with Suzuki and Sambongi (2) but the earlier emf study (3) yields a $\Delta_f H°$ which is 1.9 kcal mol^{-1} less negative. All three studies agree with the earlier conclusion of Wahlbeck and Gilles (5) that Ti_4O_7 is stable with respect to disproportionation into $Ti_3O_5(\beta)$ and TiO_2(rutile). We dismiss the $\Delta_f H°$ derived from Vasil'eva (3) since it implies the contrary when combined with our adopted S° and $C_p°$. We adopt $\Delta_f H° = -813.7 \pm 1.5\ kcal\ mol^{-1}$, where the uncertainty includes the possibility that $\Delta_{trs} H°$ and S° of $Ti_3O_5(\beta)$ are biased (6).

Heat Capacity and Entropy

$C_p°$ is based on constrained fitting of enthalpy data (679-1937 K) of Slyusar et al. (6). The constraints required that the enthalpy be zero at the reference temperature (298.15 K) and that $C_p° = 50\ cal\ K^{-1}\ mol^{-1}$ and $dC_p°/dT$ ~0.09 cal K^{-1} mol^{-1} at 300 K. The latter values are estimated by comparison with TiO_2, Ti_3O_5, Ti_2O_3 and TiO (6). Deviations of the data from the resulting fit have a pattern (6) similar to that found with the authors' data (7) for $Ti_3O_5(\beta)$. The enthalpies of Slyusar et al. (7) for TiO_2, Ti_2O_3, Ti_3O_5 and Ti_4O_7 are less than satisfactory due to inconsistencies in H near 1200 K and in the reported values of T_{fus} (6). Our constraints for Ti_4O_7 are an attempt to minimize the effects of the inconsistencies. They lead to a reasonable variation of $C_p°$ with temperature. We assume that there are no phase transitions above 298 K.

S°(298.15 K) = 47.5 ± 3 cal K^{-1} mol^{-1} is derived from the emf data of Suzuki and Sambongi (2). The uncertainty includes the possibility that $\Delta_{trs} H°$ and S° of $Ti_3O_5(\beta)$ are biased (6); excluding this possibility, we estimate an uncertainty of ±1.5 cal K^{-1} mol^{-1}. S°(298.15 K) = 49.5 cal K^{-1} mol^{-1} can be derived from the less reliable data of Vasil'eva and Shaulova (3). These authors (3) derived S°(298.15 K) = 42 cal K^{-1} mol^{-1} which is clearly too low. Unfortunately, the entropy derived form $C_p°$ data (12-300 K) of Berezovskii et al. (11) is unpublished and not yet available. These workers also measured $C_p°$ of the higher monologues Ti_5O_9, Ti_6O_{11} and Ti_9O_{17}.

Transition Data and Phase Data

Transition temperatures near 130 K and 150 K were found by use of DTA (8), elecrical conductivity (8), magnetic susceptibility (9) and x-ray diffraction (8, 10). The three crystalline phases are triclinic; the two transitions involve no change in symmetry but only rearrangements of atoms within the unit cell (10). There is obvious thermal hysteresis in the transition near 130 K. DTA endotherms (8) suggest that $\Delta_{trs} H°$ (150 K) is considerably larger than $\Delta_{trs} H°$(130 K). $\Delta_{trs} H°$ values presumably were obtained with the $C_p°$ data (11), but these are not yet available.

Ti_4O_7 is the lowest stable phase in the homologous series of structures Ti_nO_{2n-1} related to rutile. Phases exist with n=4,5,6,7,8,9 and certain higher integer values. These were reviewed in detail by Bursill and Hyde (12) in terms of the persistent structural phenomenon - crystallographic shear. Equilibrium data (1, 2) emphasize that $\Delta_r G°$ is negative, but were small in magnitude, for formation of Ti_nO_{2n-1} from its two nearest neighbors. Kinetic limitations can cause hysteresis in measured properties (1).

Fusion Data

See the liquid table for details.

Sublimation Data

$Ti_4O_7(cr)$ vaporizes incongruently such that the residue approaches the congruently vaporizing composition of $Ti_3O_5(\beta)$.

PREVIOUS: CURRENT: December 1973

TITANIUM OXIDE (Ti_4O_7) LIQUID M_r = 303.5158

$S°(298.15\ K)$ = [291.066] J K^{-1} mol^{-1}

T_{fus} = 1950 ± 20 K

$\Delta_f H°(298.15\ K)$ = [-3216.035] kJ mol^{-1}

$\Delta_{fus} H°$ = [225.936] kJ mol^{-1}

Enthalpy of Formation

$\Delta_f H°(Ti_4O_7, \ell, 298.15\ K)$ is calculated from that of Ti_4O_7(cr) by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(1950 K)-H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

$C_p°$ is estimated as 8 cal K^{-1} g-atoms^{-1}. Below the assumed glass transition at 1300 K, $C_p°$ is taken to be the same as that of the crystal. S°(298.15 K) is calculated in a manner analogous to that used for $\Delta_f H°$.

Fusion Data

Hampson and Gilles (1) reported that T_{fus} < 1943 K, which is in reasonable agreement with T_{fus} ~1955 K obtained from the liquidus curve of Brauer and Littke (2). The value of 1993 K reported by Slyusar et al. (3) is over 40° higher than our adopted value of 1950 ± 20 K. Ti_4O_7 probably melts incongruently, but the data (2) are not completely conclusive on this point.

Vaporization Data

Studies of liquid samples (4) showed that the congruently vaporizing composition is between Ti_3O_5 and Ti_4O_7. The principal products (1) of vaporization are TiO_2(g) and TiO(g).

Ground State Quantum Weight: [1] σ = [4]
Point Group: [D_{2d}]
Bond Distance: W-O = [1.81] Å
Bond Angle: O-W-O = [109.47]°
Product of the Moments of Inertia: $I_A I_B I_C$ = [7.651013 x 10^{-111}] g^3 cm^6

Enthalpy of Formation

Ackermann and Rauh (1) have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600 K by mass spectrometry, mass effusion and x-ray diffracton, and also have determined the $\Delta_f G°(W_3O_8, g)$ = -400,900 + 9054 T cal K^{-1} mol^{-1} from partial pressure measurements over $W\text{-}WO_2(cr)$. The adopted value, $\Delta_f H°(W_3O_8, g, 298.15\ K)$ = -408.7 kcal mol^{-1} was reduced from $\Delta_f H°(W_3O_8, g, 1450\ K)$ = -400.9 kcal mol^{-1}, using JANAF functions.

Source	Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}
(1)	4 $WO_2(cr) = W_3O_8(g) + W(cr)$	1300-1600	155.05	155.09	-0.04	-408.7

Heat Capacity and Entropy

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1}(6), 350 cm^{-1}(4), 242 cm^{-1}(8), 199 cm^{-1}(3) and 150 cm^{-1}(6) in order to give the entropy at 1450 K, S°(1450 K) = 208.18 cal K^{-1} mol^{-1}, corresponding to $\Delta_f S°(1450\ K)$ = -90.54 cal K^{-1} mol^{-1}, which was reported by Ackermann and Rauh (1).

The molecular configuration for $W_3O_8(g)$ was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, the three tetrahedra are connected by two common edges, and also the three tungsten atoms are in the same axis. The bond distance W-O was estimated as 1.81 Å and the bond angle < OWO = 109.47°. The principal moments of inertia are: I_A = 46.4211 x 10^{-39} and $I_B = I_C$ = 405.9772 x 10^{-39} g cm^2.

Product of the Moments of Inertia: $I_A I_B I_C$ = [3.865176 x 10^{-110}] g^3 cm^6

Enthalpy of Formation

The adopted value, $\Delta_f H°(W_3O_9, g, 298.15\ K)$ = -483.6 kcal mol^{-1}, was reduced from $\Delta_f H°(W_3O_9, g, 1450\ K)$ = -474.1 kcal mol^{-1} of Ackermann and Rauh (1), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 16000 K by mass spectrometry, mass effusion and x-ray diffraction, and determined $\Delta_f G°(W_3O_9, g)$ = -474,100 + 110.26T cal K^{-1} mol^{-1} from partial pressure measurements over W-WO_2(cr). They reviewed the previous determinations (1, 2, 3, 4) of the thermodynamic properties of sublimation of WO_3 and also pointed out that it was not possible to make quantitative observations on stoichiometric WO_3 in vacuo since it is a "bivariant" system and the ion current is not constant until the composition of the sample reaches $WO_{2.96}$. This is probably the cause of previous discrepancies in sublimation studies.

Battles (2) has also studied that the partial pressure of W_3O_9(g) over W-WO_2(cr) in the temperature range from 1389 to 1527 K. 3rd law calculation of the partial pressure data gives $\Delta_r H°(298.15\ K)$ = 148.2 kcal mol^{-1} for 4.5 WO_2(cr) = W_3O_9(g) + 1.5 W(cr) which yields $\Delta_f H°(W_3O_9, g, 298.15\ K)$ = -486.0 kcal mol^{-1}, using all JANAF functions.

Normand and Staley (3) have obtained $\Delta_r H°(1800\ K)$ = -240 kcal mol^{-1} for 3 WO_3(g) = W_3O_9(g) by mass spectrometric study of the vapor over WO_3 dissolved in $CaO-Al_2O_3-SiO_2$. The value of $\Delta_r H°$ was determined by the 2nd law method from ion intensities and leads to $\Delta_f H°(W_3O_9, g)$ = -463.4 kcal mol^{-1}. Using all JANAF functions (dated September 30, 1966). The absolute pressure values reported by Norman and Staley also appear to be quite inconsistent with the JANAF functions since they lead to -443 kcal mol^{-1} by the 3rd law method.

Source	Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

*3rd law value adopted in calculation ** 2nd law value adopted in calculation

Heat Capacity and Entropy

The heat capacity was approximated by making a tenative choice of the vibrational frequencies of 800 cm^{-1}(6), 396 cm^{-1}(3), 330 cm^{-1}(9), 200 cm^{-1}(6), and 150 cm^{-1}(6) in order to give the entropy at 1450 K. $S°(1450$ = 219.14 cal K^{-1} mol^{-1}, corresponding to $\Delta_f S°(1450\ K)$ = 110.26 cal K^{-1} mol^{-1}, reported by Ackermann and Rauh (1). The adopted value, $S°(W_3O_9, g, 298.15\ K)$ = 120.6 cal K^{-1} mol^{-1}, was reduced from the entropy at 1450 K, using JANAF functions. 2nd law calculation of the partial pressure data of Battles (2) gives $\Delta_f S°(1455\ K)$ = 71.7 cal K^{-1} mol^{-1} for 4.5 WO_2(cr) = W_3O_9(g) + 1.5 W(cr). This yields $S°(W_3O_9, g, 298.15\ K)$ = 122.4 cal K^{-1} mol^{-1}.

The molecular configuration for W_3O_9(g) is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and that each tetrahedra shares two oxygen atoms to form a planar six-member ring. The bond distance W-O is estimated as 1.81 Å and the bond angles O-W-O = 109.47° and W-O_{bridge}-W = 130.53°. The principal moments of inertia are: $I_A = I_B$ = 280.4787 x 10^{-39} and I_C = 491.3257 x 10^{-39} g cm^2.

PREVIOUS: September 1966 (1 atm) CURRENT: September 1966 (1 bar)

$S°(298.15\ K) = 228.781 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$T_{sub} = 631\ K$

$\Delta_f H°(0\ K) = -2979.041 \pm 8.9\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -3009.936 \pm 8.9\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(298.15\ K)$ of P_4O_{10}(cr) has been reported by many investigators. The most recent value, $\Delta_r H°(298.15\ K) = -719.4 \pm 2.0$ kcal mol^{-1} for the reaction P_4(α, white, cr) + 5 O_2(g) = P_4O_{10}(hex, cr) was determined by Egan and Luff (1). This $\Delta_r H°(298.15\ K)$ value was derived from energy of combustion, $\Delta_c E = -716.397$ kcal mol^{-1}, which is an average value of many measurements using three different sample forms, i.e., uncoated phosphorus, lucite-coated phosphorus and cellulose acetate-coated phosphorus. The adopted $\Delta_f H°(P_4O_{10}$, cr, 298.15 K) value was recalculated based on the P(red, V, cr) as reference state.

The enthalpy of combustion of white phosphorus was determined as -713.2 ± 1.0 kcal mol^{-1} by Holmes (2) yielding $\Delta_f H°(P_4O_{10}$, cr, 298.15 K) = -696.5 ± 1.3 kcal mol^{-1}, based on P(red, V, cr) as reference state. The enthalpy of formation of P_2O_5 from red phosphorus was reported to be -355 ± 2 kcal mol^{-1} by Koerner and Daniels (3). The product, P_2O_5, was considered to be a mixture of two forms, i.e., crystalline and amorphous. The other $\Delta_f H°(P_4O_{10}$, cr, 298.15 K) values reported by early investigators were reviewed by Egan and Luff (1).

Heat Capacity and Entropy

The heat capacities (12-324 K) and S°(298.15 K) adopted were taken from Andon et al. (4). The $C_p°$ values above 324 K were obtained by graphical extrapolation. The S°(298.15 K) value was calculated based on S°(10 K) = 0.36 cal K^{-1} mol^{-1}.

Low temperature (15-310 K) and high temperature (298.15-623.15 K) heat capacities were also measured by Thermal Laboratory (5) and Frandsen (6), respectively. The low temperature data were not adopted because they are less satisfactory than the data of Andon et al. (4). The high temperature data were not used because the sample employed for enthalpy measurements was not explicitly reported as pure hexagonal form.

Sublimation Data

The value of $\Delta_{sub}H°(298.15\ K)$ was derived from the vapor pressure data by both the 2nd and 3rd law analyses. See the P_4O_{10}(g) table for details. T_{sub} is the temperature at which the Gibbs energy change of the reaction P_4O_{10}(hex, cr) = P_4O_{10}(g) approaches zero. Sublimation temperature for P_4O_{10}(cr) was derived to be 632 K, 636 K (average of three determinations) and 623.7 K (average of two determinations) by Frandsen (6) from the vapor pressure data reported by Hoeflake and Scheffer (7), Smits (8) and Smits and Rutgers (9), respectively.

Ground State Quantum Weight: [1] $\sigma = 12$

Point Group: T_d

Bond Distances: $P-O_{apical} = 1.40 \pm 0.03$ Å $P-O = 1.60 \pm 0.01$ Å $P-P = 2.83 \pm 0.03$ Å

Bond Angles: $O_{apical}-P-O = 117 \pm 1°$ $O-P-O = 101 \pm 1°$ $P-O-P = 124°30' \pm 1°$

Product of the Moments of Inertia: $I_A I_B I_C = 2.939188 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

$\Delta_f H°(P_4O_{10}, g, 298.15\ K)$ was calculated from the enthalpies of formation and sublimation for P_4O_{10}(hex, cr). The enthalpy of sublimation, $\Delta_{sub}H°(298.15\ K)$, was derived from vapor pressure data by the second and third law methods. The results obtained are presented as follows.

Source	T/K	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
(1)	260.0-401.0	25.42±0.07	25.33	-0.39±0.13
(2)	216.2-300.4	25.59±0.06	25.35	-0.18±0.14
	283.6-389.3	25.45±0.07	25.35	-0.10±0.07

The value of $\Delta_{sub}H°(298.15\ K)$ adopted was 25.34 + 0.08 kcal mol^{-1}. There are many vapor pressure measurements reported but only the above two over P_4O_{10}(hex, cr).

It has been shown that P_4O_{10} has three solid phases and two liquid phases. The three solid phases are hexagonal, orthorhombic and tetragonal. As temperature increases, the thermal stability of P_4O_{10} follows the same order. The metastable liquid, according to data of Hoeflake and Scheffer (1) is from hexagonal form. The stable liquid is from tetragonal form. Hill et al. (3) reported that molecules of P_4O_{10} having the same structure as in the vapor are present in the hexagonal form of the solid. The vapor pressures of P_4O_{10} over different condensed phases have been measured by many investigators and reviewed by Farr (4). The complexity of the solid state of P_4O_{10} has also been discussed by Smits and Rutgers (5), Smits (6), Smits et al. (7) and Smits (8).

Heat Capacity and Entropy

The molecular structure and constants were obtained from Akishin et al. (9). The molecular structure of P_4O_{10}(g) has also been studied by the electron diffraction method by Maxwell et al. (10) and Hampson and Stosick (11). The model of the P_4O_{10} molecule was later confirmed by the x-ray method reported by Decker and MacGillavry (12) and spectroscopic studies reported by Gerding and DeDecker (13) and Sidorov and Sobolev (14). All vibrational frequencies were obtained from Egan (15) except nine frequencies, i.e. 170(3), 470(3), and 750(3) cm^{-1} which were estimated in order to make the second and third law values of $\Delta_{sub}H°(298.15\ K)$ agree. The principal moments of inertia are: $I_A = I_B = I_C = 143.2430 \times 10^{-39}\ g\ cm^2$. The heat capacities (549-1098°C or 822-1371 K) of P_4O_{10}(g) have been determined by Frandsen (16). His results are in fair agreement with the calculated ones.

Enthalpy of Formation

The adopted value, $\Delta_f H°(W_4O_{12}, g, 298.15\ K) = -670.2$ kcal mol^{-1}, was reduced from $\Delta_f H°(W_4O_{12}, g, 1450\ K) = -655.6$ kcal mol^{-1} of Ackermann and Rauh (1) who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600 K by mass spectrometry, mass effusion and x-ray diffraction, and determined $\Delta_f G°(W_4O_{12}, g) = -655{,}600 + 160.29\ T$ cal K^{-1} mol^{-1} from partial pressure measurements over the $W-WO_2(cr)$. They reviewed the previous determinations (1, 2, 3, 4) of the thermodynamic properties of sublimation of WO_3 and also pointed out that it was not possible to make quantitative observations of stoichiometric WO_3 in vacuo since it is a "bivariant" system and the ion current is not constant until the composition of the sample reaches $WO_{2.96}$. This is probably the cause of previous discrepancies in sublimation studies.

Battles (2) has also studied the partial pressure of $W_4O_{12}(g)$ over $W-WO_2(cr)$ in the temperature range from 1449 to 1527 K. 3rd law calculation of the partial pressure data gives $\Delta_r H°(298.15\ K) = 172.0$ kcal mol^{-1} for 6 $WO_2(cr) = W_4O_{12}(g) + 2\ W(cr)$ which yields $\Delta_f H°(W_4O_{12}, g, 298.15\ K) = -673.6$ kcal mol^{-1}, using all JANAF functions.

Source	Reaction	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°$, 298.15 K) kcal mol^{-1}
(1)	$6\ WO_2(cr) = W_4O_{12}(g) + 2\ W(cr)$	1300-1600	175.41	175.55	0.01	-670.2
(2)	$6\ WO_2(cr) = W_4O_{12}(g) + 2\ W(cr)$	1449-1257	176.16	172.01	-2.90 ± 0.39	-673.6

Heat Capacity and Entropy

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1}(8), 300 cm^{-1}(8), 240 cm^{-1}(8), and 200 cm^{-1}(18) in order to give the entropy at 1450 K, S°(1450 K) = 278.9 cal K^{-1} mol^{-1}, corresponding to $\Delta_f S°$(1450 K) = -160.29 cal K^{-1} mol^{-1}, reported by Ackermann and Rauh (1). The adopted value, $S°(W_4O_{12}, g, 298.15\ K) = 144.6$ cal K^{-1} mol^{-1}, was reduced from the entropy at 1450 K, using JANAF functions. 2nd law calculation of the partial pressure data of Battles gives $\Delta_f S°(1487\ K) = 82.3$ cal K^{-1} mol^{-1} for 6 $WO_2(cr) = W_4O_{12}(g) + 2\ W(cr)$. This yields $S°(W_4O_{12}, g, 298.15\ K) = 147.4$ cal K^{-1} mol^{-1}.

The molecular configuration for $W_4O_{12}(g)$ is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and that each tetrahedra shares two oxygen atoms to form a planar eight-member ring. The bond distance W-O is estimated as 1.81 Å and the bond angles O-W-O = 109.47° and $W-O_{bridge}-W$ = 160.53°. The principal moments of inertia are: $I_A = I_B = 5.935 \times 10^{-37}$ g cm^2, and $I_C = 1.094 \times 10^{-36}$ g cm^2.

PREVIOUS: June 1961 (1 atm) CURRENT: June 1961 (1 bar)

Phosphorus (P) P_1(ref)

PHOSPHORUS, BLACK (P) CRYSTAL A_r = 30.97376

$\Delta_f H°(0\ K)$ = [-11.15] kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [-12.85] kJ mol^{-1}

$S°(298.15\ K)$ = 22.59 ± 0.04 J K^{-1} mol^{-1}

Enthalpy of Formation

The enthalpy of formation is derived from $\Delta_r G°(820\ K) = 0$ for the process P(black) → P(red, IV). This calculation is based on the assumption that at 820 K the conversion of black to red phosphorus is known to occur (1).

Heat Capacity and Entropy

The thermal functions are derived from the heat capacity measurments of Stephenson et al (1) who reported measured values from 17.70 to 295.89 K.

PREVIOUS: CURRENT: June 1969

PHOSPHORUS, RED V, (P) CRYSTAL A_r = 30.97376

$S°(298.15\ K) = 22.85 \pm 0.08\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 870\ K$

$\Delta_f H°(0\ K) = -15.707\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -17.460\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 18.8 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is obtained from the enthalpies of sublimation represented by reaction I and II at 298.15 K.

(I) 4P(cr, white) + P_4(g) 14.08 kcal

(II) 4P(cr, red V) + P_4(g) 30.771 Kcal

Of the calorimetric determinations only those of Giran (12) result in a reliable value for the enthalpy of formation, 4.4 ± 0.4 kcal mol^{-1}. A comprehensive review is given by Rodewald (13).

Heat Capacity and Entropy

The only reliable low temperature measurements, 15 to 305 K, are reported by Potter (1). A value at 10 K was obtained by graphical extrapolation and a T^3 function was assumed from 0 to 10 K. High temperature heat capacities were obtained from a smooth curve joining the measurements of Kubashewski et al (2) in the range 573 to 773 K and that of Regnault (3) at 331 K with those of Potter (1). Measurements of Wigand (4) are too high. The uncertainty in the high temperature heat capacity is about 2%.

Fusion Data

The values of $\Delta_{fus}H$ and T_{fus} were calculated from the functions of the red (V) crystal and liquid. This may be compared with a reported triple point of 862.7 K by Smits and Bokhorst (5).

Sublimation Data

Vapor pressure measurements on the triclinic allotrope, T. V. A. designation V, are reported by Farr (6). These data lead to a sublimation point of 704 K and $\Delta_{sub}H(298.15\ K)$ of 30.77 ± 0.4 kcal mol^{-1} of P_4. Smits and Bokhorst (7) measured the vapor pressure of a sample whose preparation indicates that is was probably P(cr, red, V). These results lead to $\Delta_{sub}H(298.15\ K) = 30.6 \pm 1$ kcal mol^{-1} of P_4(g). An unpublished value of 30.84 kcal mol^{-1} of P_4 by Stephenson (8) is quoted by Kane.

Stevenson and Yost (9) show that the vapor density measurements of Stock et al. (10) are best explained by a vapor essentially composed of only P_4(g) below 800 K. This conclusion is supported by recent mass spectrometer measurements of Kane and Reynolds (11).

$S°(298.15\ K) = 41.077 \pm 0.08\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 195.4 \pm 0.1\ K$ (white β → white α)
$T_{fus} = 317.30 \pm 0.05\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0.521 \pm 0.001\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 0.659 \pm 0.002\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition. The enthalpies of white and red V phosphorus are tied together by the enthalpies of sublimation as determined by Giran (1) . A comprehensive review is given by Rodewald (2).

Heat Capacity and Entropy

Low temperature measurements, 15-315 K, were made by Maples (3). A Debye temperature, θ_D 124 K, was used to extrapolate to T/K = 0. Young and Hildenbrand (4) obtained heat capacities from enthalpy measurements that are 4% higher than those from the low temperature calorimeter which are preferred because of the proximity to the melting point.

Transition Data

Observed by Maples (3).

Fusion Data

The selected enthalpy of fusion is that observed by Maples (3). Young and Hildenbrand (4) obtain 125 cal mol^{-1} for the same quantity. Maples' (3) value is consistent with vapor pressures and other thermochemical data; see the liquid and $P_4(g)$ tables for details.

Sublimation Data

The vapor pressure measurements of Dainton and Kimberly (5) are the most precise and lead to $\Delta_{sub} H°(298.15\ K) = 14.08 \pm 0.2$ kcal mol^{-1} of $P_4(g)$. Measurements of Jolibois (6), Smits and Bokhorst (7), and Centzwer (8) lead to values that agree within the assigned uncertainty.

$S°(298.15\ K) = [43.01]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}(white + \ell) = 317.30 \pm 0.05\ K$

$T_{fus}(red, V + \ell) = 870\ K$

$\Delta_f H°(298.15\ K) = [0.615]\ kJ\ mol^{-1}$

$\Delta_{fus}H(white + \ell) = 0.659\ kJ\ mol^{-1}$

$\Delta_{fus}H(red, V + \ell) = 18.8 \pm 0.002\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation for P(ℓ) is calculated from that of P(white) by adding the enthalpy of fusion (white to liquid) and the difference in enthalpy, H°(317.30 K) - H°(298.15 K), between the white crystal and liquid.

Heat Capacity and Entropy

Young and Hildenbrand (1) obtained an equation from enthalpy measurements which decreased with temperature. However, a better fit to the thermochemical data results if a constant heat capacity is assumed.

The entropy is derived from low temperature measurements on white phosphorus. See the white phosphorus table for details.

Vaporization Data

MacRae and Van Voorhis' (2), determinations of the vapor pressure, 44 to 150°C, are the most precise and lead to a $\Delta_{vap}H(298.15\ K)$ of 13.504 ± 0.1 kcal mol^{-1} of P_4. *A vapor pressure equation derived by Farr (3), to fit the measurements reported* in the literature leads to a value of 13.6 ± 0.1 kcal mol^{-1} of P_4. The boiling point is calculated from the functions of P(liq) and P_4(g), and may be compared with the values of 552.7 and 553.7 resulting from Farr's (3) equation and observations of Smits and Bokhorst (4), respectively.

$^2D_{3/2}$	11360.80	4
$^2D_{5/2}$	11376.40	6
$^2P_{1/2}$	18722.65	2
$^2P_{3/2}$	18747.95	4

Enthalpy of Formation

The value adopted for the enthalpy of formation, $\Delta_f H°(298.15\ K)$ = 316.39 ± 1.0 kJ mol^{-1}, of the monatomic gas is that recommended by CODATA (1). It is derived from $\Delta_f H°(P_2, g, 298.15\ K)$, (1, 2) and the dissociation energy $D_0^0(P_2)$ = 40596 ± 20 cm^{-1} obtained by Herzberg (3).

Heat Capacity and Entropy

The electronic energy levels are given in the compilations by Moore (4, 5). There are 2.45 levels observed below the ionization potential. Only the ground state and the four lowest lying levels are used in the calculation. These are the contributions of the levels arising from three terms - $^4S°$, $^2D°$, and $^2P°$ - of the $3s^2 3p^3$ configuration. The remaining levels lie above 55000 cm^{-1} and do not contribute significantly even at 6000 K. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations beyond 6000 K may require consideration of higher excited states, estimation of missing levels, and utilization of proper cut-off procedures (6).

CODATA (1) used a slightly different values for the relative atomic mass and the fundamental constants. This causes a difference in the $S°(298.15\ K)$ value of 0.004 J K^{-1} mol^{-1}.

Enthalpy of Formation

$\Delta_f H°(P^+, g, 0\ K)$ is calculated from $\Delta_f H°(P, g, 0\ K)$ (1) using the spectroscopic value of IP(P) = 84580 ± 10 cm^{-1} (1011.80 ± 0.12 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(P^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(P, g, 0\ K)$ by using IP(P) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for P(g), $P^+(g)$, and $e^-(g)$. $\Delta_f H°(P \rightarrow P^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is approximately 52000 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

PREVIOUS: CURRENT: December 1982 (1 bar)

PHOSPHORUS, ION (P^-) IDEAL GAS M_r = 30.97431

EA(P, g) = 0.7465 ± 0.0003 eV

$S°(298.15\ K)$ = 169.124 ± 0.001 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 243.527 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [238.717] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^3P_2$	0.0	5
$^3P_1$	181.0	3
$^3P_0$	263.0	1
$^1D_2$	6675	5
$^1S_0$	16131	1

Enthalpy of Formation

$\Delta_f H°(P^-, g, 0\ K)$ is calculated from $\Delta_f H°(P, g, 0\ K)$ (1) using the adopted electron affinity of EA(P) = 0.7465 ± 0.0003 eV (72.026 ± 0.029 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on tunable laser photodetachment threshold studies (3, 4). Additional information on $P^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 5), Rosenstock et al. (6) and Massey (7).

$\Delta_f H°(P^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(P, g, 0\ K)$ by using EA(P) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $P^-(g)$, P(g), and $e^-(g)$. $\Delta_r H°(P^- \rightarrow P + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (6). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $P^-(g)$ is given by Hotop and Lineberger (2, 5), Rosenstock (6), and Massey (7). The fine sturcture seperation has been measured experimentally via a tunetable laser photodetachment threshold technique (3, 4) and is that recommended by Hotop and Lineberger (2).

Enthalpy of Formation

The dissociaton energy, D_0^0, of PS(g) is estimated to be 140 ± 25 kcal mol^{-1} by comparison with the corresponding quantity for PO(g) and from a linear Birge-Sponer extrapolation of the third excited ($C^2\Sigma$) electronic state potential function. It is assumed that the $C^2\Sigma$ state dissociates to S(g) in its ground (^3P) state and P(g) in its first excited (^2D) state. The fundamental vibrational frequency in the $C^2\Sigma$ state (ω_e') is 531.8 ± 2.5 cm^{-1} and the corresponding anharmonic term ($\omega_e x_e$) is 2.6 ± 0.5 cm^{-1}. These constants are calculated from a reanalysis of the spectral data of Dressler (1). The corresponding enthalpy of formation of PS(g) is 37.3 ± 25 kcal mol^{-1}. The excited state ($C^2\Sigma$) data are used to calculate D_0^0 instead of the ground state ($X^2\Pi$) data because the vibrational constants of the upper level are known more accurately and because the extrapolation is 50 kcal mol^{-1} smaller for this level.

Heat Capacity and Entropy

The spectra of PS(g) have been studied by Dressler (1) in the near UV and visible regions. He reported the above electronic levels which correspond to the doublet pi ground state and two of the excited levels ($B^2\Pi$, $C^2\Sigma$). The level of the first excited electronic state ($A^2\Sigma$) is estimated by analogy with NO(g).

Dressler (1) estimated the value of the rotational constant B_e. The value of α_e is calculated from the Morse potential function. The bond distance is calculated from B_e. The fundamental vibrational frequency ω_e and the anharmonic vibrational term $\omega_e x_e$ are calculated from a reanalysis of the spectral data reported by Dressler (1).

PHOSPHORUS (P_2) IDEAL GAS M_r = 61.94752

$S°(298.15\ K) = 218.13 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 145.47 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 143.65 \pm 2.1\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^1\Sigma$	0	1

$\omega_e = 780.43\ cm^{-1}$ $\omega_e x_e = 2.804\ cm^{-1}$ $\sigma = 2$

$B_e = 0.30327\ cm^{-1}$ $\alpha_e = 0.00142\ cm^{-1}$ $r_e = 1.8943$ Å

Enthalpy of Formation

Stevenson and Yost (1) have shown that the vapor density measurements of Stock et al. (2) best fit a vapor composed of $P_2(g)$ and $P_4(g)$. From these data, Farr (3) calculated the equilibrium constants which lead to $\Delta_r H°(298.15\ K) = 54.59 \pm 0.01$ kcal mol^{-1} for the process $P_4(g) \rightarrow P_2(g)$; from which the value for $\Delta_f H°(P_2, g, 298.15\ K)$ is calculated using $\Delta_f H°(P_4, g, 298.15\ K) = 30.77$ kcal mol^{-1}.

Heat Capacity and Entropy

Molecular and spectroscopic constants are those listed by Herzberg (4). More recent measurements of Dressler (5) are in agreement with the values selected by Herzberg (4).

The dissociation energy, $D_0^0 = 116 \pm 1$ kcal mol^{-1}, is given by Gaydon (6).

PREVIOUS: June 1961 (1 atm) CURRENT: June 1961 (1 bar)

$S°(298.15\ K) = 280.0 \pm 0.4\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 66.2 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 58.9 \pm 2.1\ kJ\ mol^{-1}$

Vibrational Levels and Degeneracies

ν, cm^{-1}
606 (1)
363 (2)
464.5(3)

Point Group: T_d $\sigma = 12$

Bond Length: P-P = 2.21 ± 0.2 Å

Bond Angle: P-P-P = 109.4712°

Product of the Principal Moments of Inertia: $I_A I_B I_C = 15.8528 \times 10^{-114}\ g^3\ cm^6$

Enthalpy of Formation

Taken as the enthalpy of formation of white phosphorus.

Heat Capacity and Entropy

The frequencies and degeneracies are those assigned by Gutowsky and Hoffman (1). Molecular parameters of the gas were determined from electron diffraction measurements by Maxwell et al. (2). Thomas and Gingrich (3) obtained a P-P distance of 2.25 Å from X-ray studies on the liquid. On the basis of the selected values for P(white), a 3rd law entropy of 66.89 cal $K^{-1}\ mol^{-1}$ (for p=1 atm) is derived for $P_4(g)$. The principal moments of inertia are: $I_A = I_B = I_C = 25.1209 \times 10^{-39}\ g\ cm^2$.

PHOSPHORUS SULFIDE (P_4S_3) CRYSTAL M_r = 220.07504

$S°(298.15\ K) = [200.832]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 440\ K$

$\Delta_f H°(298.15\ K) = [-224.647]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [9.204]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(298.15\ K)$ is estimated from vapor density reported by Yost and Russell (1). T_{fus} is from Yost and Russell (1). Other data estimated.

PHOSPHORUS SULFIDE (P_4S_3) LIQUID M_r = 220.07504

$S°(298.15\ K) = [207.097]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 440\ K$

$\Delta_f H°(298.15\ K) = [-220.784]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [9.204]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(P_4S_3, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(440 K)-H°(298.15 K), between the crystal and liquid.

Fusion Data

T_{fus} is from Yost and Russell (1).

Vaporization Data

T_{vap}(1 atm) = 680 K is given by Yost and Russell (1).

Reference

Lead (Pb) Pb_1(ref)

$S°(298.15\ K) = 64.785 \pm 0.54\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 600.58 \pm 0.00\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 4.77 \pm 0.01\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Heat Capacity measurements have been reported by Horowitz, et al. (1-4 K, 14-21 K, 64-77 K, 1), Meads, et al. (15-300 K, 2), Douglas and Devir (298.15 K), 3), and many others whose work is listed by Kelley (4).

Heat capacities from 15 to 300 K and 1 to 4 K (in superconducting state) were taken from Meads et al. (2) and Horowitz et al. (1), respectively. The missing data below the melting point were obtained by graphical extrapolation and joined smoothly to the data of Douglas and Dever (3) on approaching the melting point.

Fusion Data

The melting point of pure Pb(cr) was found by McLaren and Mardock (5) to be 327.426 ± 0.002°C. $\Delta_{fus}H°$ was given by Douglas and Dever (3).

Sublimation Data

The enthalpy of sublimation, $\Delta_{sub}H°(298.15\ K)$, is the enthalpy of formation of the ideal gas, $\Delta_f H°(298.15\ K)$. See the ideal gas table for details.

PREVIOUS: CURRENT: March 1962

LEAD (Pb) LIQUID A_r = 207.2

$S°(298.15\ K) = [71.710]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [4.283]\ kJ\ mol^{-1}$

$T_{fus} = 600.58 \pm 0.00\ K$ $\Delta_{fus}H° = 4.77 \pm 0.01\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of the liquid, $\Delta_f H°(298.15\ K)$, is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(600.58\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Heat capacity values from T_{fus} to 1200 K were taken from Douglas and Dever (1), Heat capacity values below T_{fus} and above 1200 K were extrapolated, a glass transition being assumed at 400 K.

The entropy is calculated in a manner anologous to that used for the enthalpy of formation.

Vaporization Data

T_{vap} is calculated as the temperature at which $\Delta_r G° = 0$ for the process Pb(ℓ) = Pb(g). $\Delta_{vap}H°$ is calculated as the corresponding enthalpy of formation difference at T_{vap}. At temperatures below T_{vap}, the amount of $Pb_2(g)$ in the vapor is negligible.

Enthalpy of Formation

The adopted enthalpy of formation value for Pb(g), $\Delta_f H°(298.15\ K)$ = 195.20 ± 0.80 kJ mol^{-1}, is that recommended by CODATA (1). This value was calculated, according to CODATA, from the vapor pressure measurements cited by Hultgren et al (2) and the more recent measurements by Andon et al. (3), Chang, et al. (4), Kim and Cosgarea (5), and Shiu and Miner (6).

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (7, 8), is incomplete because many theoretically predicted levels have not been observed. Our calcualtions indicate that any reasonable method of filling in these missing levels (for n<21) and cutting off the summation in the partition function (9) has little effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than those listed above; the next excited state is approximately 34950 cm^{-1} above the ground state. Although we list only a few levels above, all levels listed by Moore (7, 8) are considered in the calculation. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calcualtions above 6000 K may require consideration of the excited states (n>21) and use of different fill and cutoff procedures (9).

The thermal functions at 298.15 K differ from the CODATA recommendations (1) for two reasons. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas CODATA recommendations are based on 1 atm. Second, small changes, 0.005 J K^{-1} mol^{-1}, arise due to the use of slightly different values for the fundamental constants.

Enthalpy of Formation

$\Delta_f H°(Pb^+, g, 0 K)$ is calculated from $\Delta_f H°$(Pb, g, 0 K) (1) using the spectroscopic value of IP(Pb) = 59819.4 ± 0.3 cm^{-1} (715.599 ± 0.004 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ mol^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Pb^+, g, 298.15 K)$ is calculated from $\Delta_f H°$(Pb, g, 0 K) by using IP(Pb) with JANAF (1) enthalpies, H°(0 K) − H°(298.15 K), for Pb(g), $Pb^+(g)$, and $e^-(g)$. $\Delta_f H°(Pb \rightarrow Pb^+ + e^-, 298.15 K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15 K)$ should be changed by −6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first excited state; the next excited state is 57911 cm^{-1}, above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

PREVIOUS: CURRENT: March 1983 (1 bar)

J. Phys. Chem. Ref. Data, Vol. 14, Suppl. 1, 1985

LEAD, ION (Pb^-) IDEAL GAS M_r = 207.20055

EA(Pb, g) = 0.364 ± 0.008 eV

$S°(298.15\ K)$ = 186.900 ± 0.002 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 160.76 ± 3 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [153.882] kJ mol^{-1}

Electonic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^4S_{3/2}$	0.0	4

Enthalpy of Formation

$\Delta_f H°(Pb^-, g, 0\ K)$ is calculated from $\Delta_f H°(Pb, g, 0\ K)$ (1) using the adopted electron affinity of EA(Pb) = 0.364 ± 0.008 eV (35.120 ± 0.772 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Pb^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Pb^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Pb, g, 0\ K)$ by using EA(Pb) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Pb^-(g)$, Pb(g), and $e^-(g)$. $\Delta_r H°(Pb^- \rightarrow Pb + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Pb^-(g)$ is given by Hotop and Lineberger (2, 4) and Rosenstock et al. (5). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

$S°(298.15\ K) = 91.34 \pm 1.7\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1386.5 \pm 1.5\ K$

$\Delta_f H°(0\ K) = -98.55 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = -98.32 \pm 2.1\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 18.83 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

2nd and 3rd law analyses are made of the equilibrium data of Jellinek et al. (1), Sudo (2), and Stubbles and Birchenall (3), the Gibbs free energies (via emf measurements) of Kapustinskii and Makolkin (4) and of Kiukkola and Wagner (5) and the emf data reported by Thompson and Flengas (6). The results of our analyses using auxiliary data (7) are summarized in the following table.

Source	Reaction*	T/K	Data Points	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15\ K)$ kcal mol^{-1}

(6)	E	773-1071	12	-40.7±0.5	-39.63	1.2 ±0.6	-23.2

*A) $Pb(\ell) + H_2S(g) = PbS(cr) + H_2(g)$

B) $Pb(cr) + H_2S(g) = PbS(cr) + H_2(g)$

C) $Pb(cr) + S(\ell) = PbS(cr)$

D) $Pb(\ell) + S(\ell) = PbS(cr)$

E) $Pb(\ell) + 1/2\ S_2(g) = PbS(cr)$

The experiences of Jellinek et al. (1) are unsatisfactory (8) and are superseded by two later studies (2, 3) of the same equilibrium. The Gibbs energies of Kapustinskii and Makolkin (4) may be dismissed as biased on the basis of inconsistencies in both $\Delta_f H°$ and entropy (drift). The other studies (2, 3, 5, 6) are consistent with the adopted $\Delta_f H°(298.15\ K)$ of -23.5 ± 0.5 kcal mol^{-1}.

We also calculate $\Delta_f H° = -23.5$ kcal mol^{-1} from $\Delta_r H°(293\ K) = -13.38 \pm 0.2$ kcal mol^{-1} for the reaction $Pb(NO_3)_2(aq, 3000\ H_2O) + H_2S(aq) + PbS(cr) + 2\ HNO_3(aq, 2000\ H_2O)$ studied calorimetrically by Zeumer and Roth (9). The uncertainty of this calorimetric $\Delta_r H°$ may approach ±1 kcal mol^{-1} due to the auxiliary data (10) and approximations used in our calculation. Recent DTA data (11) for $Pb(cr) + S(\ell) \rightarrow PbS(cr)$ gave $\Delta_r H°(480\ K) = -23.4 \pm 0.3$ kcal mol^{-1} which we reduce to $\Delta_f H°(298.15\ K) = -22.5 \pm 1$ kcal mol^{-1}. The uncertainty assigned (11) to $\Delta_r H°$ appears to be too optimistic. Korshunov (12) obtained $\Delta_f H° = -22.38$ kcal mol^{-1} by combustion of S-Mg-Pb mixtures in a bomb, but the chemical reactions probably were not characterized adequately.

Heat Capacity and Entropy

$C_p°$ is from the work of Parkinson and Quarrington (13, $C_p°$ given as smoothed values, 20-260 K) and of Anderson (14, 54-289 K) which were graphically smoothed and extrapolated to 300 K. The data of Parkinson and Quarrington and Anderson are in good agreement; Anderson's values show more scatter. The largest deviation of the Parkinson and Quarrington values from the adopted values is +0.4% at 210 K. Anderson's points are mostly within less than ±1% of the selected values.

Above 300 K, $C_p°$ values are derived from the drop-calorimetric enthalpies of Thompson and Flengas (15, 353-1281 K) with the constraint to join smoothly with the low temperature data. The observed enthalpies differ from the adopted values by +4% at 400 K; above 500 K the deviation is generally within ±0.4%.

Also considered were the low temperature heat capacities measured by Eastman and Rodebush (16, 64-283 K) and Kelley's equations (17) which are based on the work of Bornemann and Hengstenberg (18, 273-873 K). The Eastman and Rodebush data appears to be high above 200 K. At 900 K the enthalpy calculated from Kelley's equation is 4% higher than the adopted value.

S°(20 K) of 0.83 cal K^{-1} mol^{-1} given by Kelley and King (19) is adopted here.

Fusion Data - See the liquid table for details.

Sublimation Data - See the ideal gas table for details.

LEAD SULFIDE (PbS) LIQUID M_r = 239.26

$S°(298.15\ K) = [100.795]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [-84.064]\ kJ\ mol^{-1}$

$T_{fus} = 1386.5 \pm 1.5\ K$ $\Delta_{fus}H° = 18.83 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(PbS, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, $H°(1386.5\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of PbS(ℓ) is estimated to be 16.0 cal K^{-1} mol^{-1}. This appears reasonable as the $C_p°$ value for PbO(ℓ) is 15.535 cal K^{-1} mol^{-1} (12). A glass transition is assumed at 900 K. Below this temperature, the heat capacity values used are those of PbS(cr). S°(298.15 K) is calculated in a manner similar to that used for $\Delta_f H°(298.15\ K)$.

Fusion Data

Employing cryoscopic measurements, Pelton and Flengas (1) and Bell and Flengas (2) determined the melting point of PbS to be 1113.4°C and 1111.9°C, respectively. Pelton and Flengas (1) estimated an accuracy of ±1°C. Miller and Komarek (3), in studying the retrograde solubility in the Pb-S system, reported T_{fus} = 1113.3 ± 0.5°C. The latter authors have summarized many early determinations of T_{fus} which were in the range 1103-1135°C. We adopt 1386.5 ± 1.5 K for T_{fus} of PbS.

Kelley (4) adopted $\Delta_{fus}H°$ = 4.150 kcal mol^{-1} based on melting point data obtained by Friedrich (5) for the PbS-Cu_2S system and by Truthe (6) for the PbS-$PbCl_2$ system. Maier (7) recalculated $\Delta_{fus}H°$ from Friedrich's data and obtained 4.155 kcal mol^{-1}. Kelley (4) also calculated $\Delta_{fus}H°$ = 5.03 kcal mol^{-1} from data on the PbS-Ag_2S system obtained by Friedrich. Other inconclusive works are discussed by Kelley (4). In the preceding calculations, $\Delta_{fus}H°$ was derived from a graph of log x versus 1/T where x is the mole fraction of PbS in the melt and T is the liquidus temperature.

We calculate a $\Delta_{fus}H°$ value for each melting point-composition data pair and plot this value against ΔT, the melting point depression of PbS. The resulting plot is extrapolated to ΔT = 0 to obtain $\Delta_{fus}H°$. Friedrich's data then yields $\Delta_{fus}H°$ = 4.33 ± 0.15 kcal mol^{-1}. Truthe's data has considerable scatter but indicates a value of 4-6 kcal mol^{-1} for $\Delta_{fus}H°$. An analysis of the data reported by Kohlmeyer and Monzer (8) for the PbS-PbO system yields $\Delta_{fus}H°$ = 5 ± 1 kcal mol^{-1}. Unfortunately, these three studies necessitate long extrapolations as the ΔT values are in the range 60-550 K. However, these three binary systems form simple, single eutectic phase diagrams and all are consistent with a $\Delta_{fus}H°$ value of 4.5 kcal mol^{-1}.

Recent work by Pelton and Flengas (1) on PbS-alkali halide systems involved ΔT values of 2-17 K so that a much shorter extrapolation is possible. An analysis of their data is tabulated below.

System	Data Points	$\Delta_{fus}H°$, kcal mol^{-1}
PbS-NaCl	3	8.5
PbS-KCl	10	4.5
PbS-RbCl	2	4.3
PbS-CsCl	2	4.6

Even in the PbS-KCl system, the scatter is such that it is impossible to precisely define $\Delta_{fus}H°$. We adopt a value of $\Delta_{fus}H°$ = 4.5 ± 1.5 kcal mol^{-1}. This value is consistent with all systems discussed above except for PbS-NaCl.

It should be noted that our analyses treated all systems as though no association, dissociation, or compound formation occurs in the melt. It is possible that the occurrence of any or all of these factors would cause the data to be consistent with a $\Delta_{fus}H°$ which might be larger than the adopted value and even outside our uncertainty limits. For example, Pelton and Flengas (1) discussed their results in the PbS-alkali halide systems in terms of an estimated $\Delta_{fus}H°$ = 8.7 kcal mol^{-1}. Their conclusions need modifications with use of our adopted $\Delta_{fus}H°$ = 4.5 kcal mol^{-1}. In addition Blachnik and Kluge (9) have compared SnS and PbS; a difficulty arises in that PbS does not have the same crystal structure as GeS and SnS (9). Thus, $\Delta_{fus}S°$ is not necessarily expected to the same for all three species.

Decomposition Data

Kohlmeyer (10, 11) reported that, although PbS(ℓ) had an apparent boiling point of 1617 K, the vaporization did not yield solely PbS(g). Decomposition occurred to yield sulfide molecules in the melt which were rich in Pb. The temperature at which the fugacity of PbS(g) is 1 atm for PbS(ℓ) = PbS(g) is calculated to be 1593 K. A similar calculation for the reaction PbS(ℓ) = Pb(ℓ) + 1/2 S S_2(g) yields 1999 K.

Enthalpy of Formation

Vago and Barrow (1) observed the convergence in the E-X system at 2715 Å. The dissociation energy for PbS(g) is calculated to be 81.85 ± 0.40 kcal mol^{-1}. Barrow et al. (2) analyzed the PbS absorption spectrum in terms of type C coupling and assigned the electronically excited E state to be 0^+. If the non-crossing rule is applicable (2), then the most likely dissociation products are $Pb(^3P_1)$ and $S(^3P_1)$. Using auxiliary data (3), $\Delta_f H°(PbS, g, 298.15\ K) = 32.00 \pm 0.40$ kcal mol^{-1}.

Colin and Drowart (4) have studied the sublimation and dissociation of PbS by means of a Knudsen effusion cell coupled with a mass spectrometer. A 2nd and 3rd law analysis by Colin and Drowart (4) of four sets of experiments (865-1100 K) yielded an average value of 55.7 ± 1.4 kcal mol^{-1} for the enthalpy of sublimation. It is anticipated that this result is roughly 0.5 kcal mol^{-1} too large since the Gibbs energy functions for the sublimation used by Colin and Drowart (4) are approximately 0.5 cal K^{-1} mol^{-1} greater than those presently adopted at 1000 K (3).

Colin and Drowart (4) presented data for 13 experiments in which either Pb, S_2 or both Pb and S_2 partial pressures were measured in addition to the PbS partial pressure. The missing pressure is calculated using the formula $[P(Pb)/P(S_2)][M_r(S_2)/M_r(Pb)]^{1/2} = 2$ as in Colin and Drowart (4).

* A) $PbS(g) = Pb(g) + 1/2\ S_2(g)$ B) $PbS(cr) = PbS(g)$

* One point rejected due to statistical test. ** Actual data not presented, smoothed data used.

The value adopted for $\Delta_f H°(PbS, g, 298.15\ K)$ is 31.5 ±1.5 kcal mol^{-1}. Most of the uncertainty is attributable to the possible decomposition and/or reaction during sublimation. Colin and Drowart (4) and Isakova et al. (10) considered the effect of decomposition whereas many of the other investigators analyzed their data in terms of PbS(g) formation only. In addition, Hansen and Munir (11) attest to the congruency of sublimation using x-ray observations on samples which had lost at least 30% of their initial weight as a result of heating. The adopted $\Delta_f H°(298.15\ K)$ is somewhat of a compromise between the spectroscopic work (1), the mass spectrometric work (4) and the bulk of the sublimation studies. Correspondingly, $D_0^0(PbS, g) = 82.4 \pm 1.5$ kcal mol^{-1}.

$D_0^0(PbS, g) = 86.5$ kcal mol^{-1} is calculated by applying the Hildenbrand formula (12) to the linear Birge-Sponer extrapolation of the ground state vibrational levels. Using auxiliary data (3), $\Delta_f H°(298.15\ K) = 27.4$ kcal mol^{-1} is obtained.

Heat Capacity and Entropy

The tabulated electronic and molecular constants are taken from Rosen (13) as reviewed and compiled by Barrow. The constants came from the work of Bell and Harvey (14), Rochester and Howell (15), Vago and Barrow (1) and Barrow et al. (2). The state designations are those which are consistent with type C coupling. In this case, the state designations Σ, Π, etc., no longer have meaning. The estimated values in the tabulation are derived from comparisons of known values in the PbS(g) and PbO(g) systems (3). The functions are calculated from the partition function $Q = Q_{t_i} r Q_r^i Q_v^i g_i e^{-C_2 \varepsilon_i/T}$; the values for Q_r^i and Q_v^i were calculated with first order anharmonic corrections.

$S°(298.15\ K) = [281.334]\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 336.4 \pm 19.2\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 332.6 \pm 19.2\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$[^3\Sigma_g^-]$	0	[3]

$\omega_e = 256.5\ cm^{-1}$ $\omega_e x_e = 2.96\ cm^{-1}$ $\sigma = 2$
$B_e = [0.01727]\ cm^{-1}$ $\alpha_e = [0.00020]\ cm^{-1}$ $r_e = [3.08]$ Å

Enthalpy of Formation

The enthalpy of formation is calculated from the dissociation energy of $Pb_2(g)$ as reported by Gaydon (1).

Heat Capacity and Entropy

The values of ω_e and $\omega_e x_e$ are obtained from Herzberg (2). Those for B_e and α_e are estimated according to the method suggested by Herzberg. The bond distance (r_e) is calculated from the moment of inertia, $I = 1630 \times 10^{-40}$ g cm^2, estimated by Kelley and King (3). The ground state configuration is assumed to be $^3\Sigma$ by comparison to that for $Si_2(g)$ reported by Douglas (4).

PREVIOUS: CURRENT: December 1983 (1 bar)

$S°(298.15\ K) = 76.78 \pm 0.30\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 312.65 \pm 0.1\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 2.19 \pm 0.09\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The thermal functions for Rb(cr) are derived following CODATA recommendations (1). That is, these functions are based on the previous evaluation of Hultgren et al. (2), Martin (3, 4), and Shpil'rain et al. (5). The prime sources of data are: Lien and Phillips (0.19-4.1 K, 6), Filby and Martin (0.4-1.5 K, 3-320 K, 7), McCallum and Silsbee (1.3-12 K, 8), Dauphinee, Martin, and Preston-Thomas (25-300 K, 9), and Martin (0.4-3 K, 4).

Fusion Data

The adopted fusion temperature, T_{fus} = 312.65±0.1 K, is that recommended by Ohse et al. (10) based on their analysis of seven experimental studies: Rengade (312.15±0.05 K, 11), Dauphine et al. (311.90±0.5 K, 9), Weatherford et al. (312.54 K, 12), Filby and Martin (312.65±0.01 K, 7), Basin et al. (312.31±0.05 K, 13), Ott et al. (312.45 K, 14), and Martin (312.47 K, 4).

The adopted enthalpy of fusion, $\Delta_{fus} H°$, 2.19±0.09 kJ mol^{-1}, is derived from the studies of Rengade (11), Filby and Martin (7), and Martin (4); all three results being within 1 cal mol^{-1}.

Sublimation Data

Refer to the ideal gas tables for details.

RUBIDIUM (Rb) LIQUID A_r = 85.4678

$S°(298.15\ K) = [83.764]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 312.65 \pm 0.1\ K$

$\Delta_f H°(298.15\ K) = [2.184]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 2.19 \pm 0.09\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the crystal by adding the enthalpy of fusion and the difference in enthalpy, H°(298.15 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The adopted heat capacity values for Rb(ℓ) are those recommended by Fink and Leibowitz (1). These authors reviewed the liquid phase heat capacity and enthalpy studies for all alkali metals and recommended a Cp° equation for Rb(ℓ) based on their evaluation of four enthalpy (2, 3, 4, 5) and three heat capacity (6, 7, 8) experimental studies. These studies provided information in the liquid region up to 1334 K.

The equation recommened by Fink and Liebowitz (1) is $Cp° = 35.494 - 0.012864\ T + 0.85409 \times 10^{-5}\ T^2$ ($J\ K^{-1}\ mol^{-1}$).

Vaporization Data

Refer to the ideal gas table for details.

Enthalpy of Formation

The enthalpy of formation of rubidium gas is chosen to be the value recommended by CODATA (1). This value was obtained from 2nd and 3rd law analysis of the vapor pressure studies reported by Hultgren et al. (2). As stated by CODATA (1), the correction for the presence of the dimer in the vapor phase was made using a virial treatment, since the dissociation energy of $Rb_2(g)$ was not well established.

The six studies used by Hultgren et al. (1) are: Volyak et al. (594-970 K, 3), Achener (745-1260 K, 4), Tepper et al. (716-1353 K, 5), Buck and Pauly (307-363 K, 6), Killian (312-377 K, 7), and Scott (365-400 K, 8).

Heat Capacity and Entropy

The thermal functions for the five alkali metal monatomic gases are calculated by the same procedure. Oberved and estimated atomic energy levels are included in the partition function calculation, using an ionization potential lowering (IP-kT) technique as the cutoff procedure in the energy level summation (11).

The lowest lying levels for these metals [14904 cm^{-1} (Li), 16956 cm^{-1} (Na), 12985 cm^{-1} (K), 12578 cm^{-1} (Rb), and 11178 cm^{-1} (Cs)] do not contribute to the thermal functions below ~1000 K; there is only a translational contribution below this temperature. Above this approximate temperature, the thermal functions become increasingly sensitive to the partition function cutoff procedure used, due to the combined effect of the observation of atomic energy levels of high principal quantum number and a low ionization potential. Energy levels have been observed up to n = 42 (Li), 59(Na), 79(K), 77(Rb), and 73(Cs). However, not all predicted levels have been observed for each of these principal quantum numbers. The ionization potentials vary from 43487.29 cm^{-1} for Li to 31406.1 cm^{-1} for Cs. In calculating the thermal functions with the inclusion of missing levels up to the high principal quantum numbers just mentioned, the Gibbs energy functions show significant differences (depending on the cutoff procedure) above 3000 K (11).

The atomic energy levels have been taken from the compilation of Moore (9, 10). Our calculated values for the thermal functions are similar to those recommended by CODATA (1). They do differ for two reasons, however. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, the entropies at 298.15 K for all alkali metal gases differs by ~0.004 J K^{-1} mol^{-1}, presumably due to the use of slightly different values for auxiliary data.

$IP(Rb^+, g) = 220048 \pm 30\ cm^{-1}$
$S°(298.15\ K) = 164.330 \pm 0.02\ JK^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 485.224\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = [490.129]\ kJ\ mol^{-1}$

Electronic Level and Quantum Weight

State	ε_i cm^{-1}	g_i
$^1S_0$	0	1

Enthalpy of Formation

$\Delta_f H°(Rb^+, g, 0\ K)$ is calculated from $\Delta_f H°(Rb, g, 0\ K)$ (1) using the spectroscopic value of IP(Rb) = 33690.81 ± 0.01 cm^{-1} (403.032 ± .0001 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Rb^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Rb, g, 0\ K)$ by using IP(Rb) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Rb(g), $Rb^+(g)$, and $e^-(g)$. $\Delta_r H°(Rb \rightarrow Rb^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state; the first excited state is approximately 126454 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

Enthalpy of Formation

The enthalpy of formation, at 0 K, for $Rb^-(g)$ is calculated from the adopted electron affinity, EA(Rb, g) = 0.48592 ± 0.00002 eV (46.884±0.002 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (6), was measured by a tunable laser photodetachment threshold technique (2). Additional discussion on $Rb^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (1, 6), Rosenstock et al. (3), and Massey (4).

$\Delta_f H°(Rb^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Rb, g, 0\ K)$ by using EA(Rb, g) with JANAF (5) enthalpies, $H°(0\ K)-H°(298.15\ K)$, for $Rb^-(g)$, Rb(g), and $e^-(g)$. $\Delta_r H°(Rb^- + Rb + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (3). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention which excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state configuration for $Rb^-(g)$ is given by Hotop and Lineberger (1, 6) and Rosenstock et al. (3). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.

D_0^0 = 46.91 ± 1.9 kJ mol^{-1} (natural abundance)
$S°(298.15\ K)$ = 271.07 ± 0.08 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 117.34 ± 2.5 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = 113.29 ± 2.5 kJ mol^{-1}

Spectroscopic Data for $^{85}Rb_2$ (Ground State: $^1\Sigma_g^+$) in cm^{-1}

ω_e = 57.747 $\omega_e x_e$ = 0.1582
B_e = 0.02278 α_e = 4.7 x 10^{-5}
D_e = 1.5 x 10^{-8} r_e = 4.173 Å

Heat of Formation

Using the adopted value of the dissociation energy for $Rb_2(g)$, D_0^0 = 46.91 kJ mol^{-1} (natural abundance Rb_2) as deduced from the ^{85}Rb dissociation energy from reference (4) ($D°$ = 47.277 ± 1.93 kJ mol^{-1}) and the recommended $\Delta_f H°(Rb, g, 0\ K)$ = 82.17 kJ mol^{-1} from NBS (5), we calculate $\Delta_f H°(Rb_2, g, 0\ K)$ = 117.34 kJ mol^{-1}. Using the NBS enthalpy value for Rb(cr) ($H°(298.15\ K)-H°(0\ K)$ = 7.489 kJ mol^{-1}) and the current JANAF value for $H°(298.15\ K)-H°(0\ K)$ of $Rb_2(g)$, we obtain $\Delta_f H°(Rb_2, g, 298.15\ K)$ = 113.29 kJ mol^{-1}. Note that in a mass spectrometric study by Piacente et al. (6), the dissociation energy of $Rb_2(g)$ was determined as 41.84 ± 2.1 kJ mol^{-1}. This value appears to be too low when compared to the alkali metal group trends apparent in plots of D_0^0 versus r_e or D_0^0 versus group member.

Heat Capacity and Entropy

The heat capacity and entropy were calculated using a direct summation technique similar to the $Li_2(g)$ species (7) using the data for the $^{85}Rb_2$ species given above (1,2). Since insufficient spectroscopic data exist for the lower lying excited electronic states, we performed the calculation on the ground state only as discussed in the $K_2(g)$ table (7). Separate calculations were performed on the isotopic species $^{85}Rb_2$, $^{87}Rb_2$, and $^{85}Rb^{87}Rb$ and the results combined according to the natural atomic isotopic abundances (3): ^{85}Rb, 72.165%; ^{87}Rb, 27.835%. Spectroscopic input data for the calculation of the isotopic species were calculated from the $^{85}Rb_2(g)$ data using reduced mass scaling. The rotational levels were weighted according to the nuclear spins of the atoms (^{85}Rb, I=5/2; ^{87}Rb, I=3/2) as follows: $^{85}Rb_2$, *even J weight = 0.583, odd J weight = 0.471*; $^{87}Rb_2$, even J weight = 0.625, odd J weight = 0.375; $^{85}Rb^{87}Rb$, equal weights of 0.5.

Based on the results for the $Cs_2(g)$ calculation (7), neglect of the excited states probably results in negligible uncertainties in the thermodynamic functions (except for Cp) at temperatures below ca. 2000 K. We estimate that the entropy and Gibbs energy function at 3000 K are too low by ca. 0.4 J K^{-1} mol^{-1} due to the neglect of the excited states. The adopted value of $S°(298.15\ K)$ is 0.07 J K^{-1} mol^{-1} larger than that adopted by Gurvich, et al. (8).

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore (1, 9). Many of the theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (2) has little effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels; the first excited level is over 54620 cm^{-1} above the ground state. Therefore, we list the ground state only. Extension to higher temperatures may require consideration of excited states and utilization of different fill and cutoff procedures (2).

Thermodynamic functions at 298.15 K are recommended by CODATA (3) for all rare gases except radon. This table agrees with other tabulations except for two minor changes. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the other tabulations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the rare gases arise due to the use of slightly different values for R and the relative atomic mass; this table uses R = 8.31441 J K^{-1} mol^{-1}. With some minor changes, our tables agree within the estimated uncertainty with those by Hilsenrath et al. (5), Gurvich et al. (8), and Wagman et al. (10). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which in this tabulation are based on the 1981 scale (6) and the 1973 values (7), respectively.

Phase Data

Hultgren et al. (4) had recommended a melting point of 202 K and a boiling point of 211 K (1 atm). These values are provided for the convenience of the reader and have not been evaluated by the present authors. As a result of the low values, the reference state for radon is chosen to be the ideal gas at all temperatures. This may differ from the choice of other authors.

Enthalpy of Formation

The ionization limit of neutral radon (86692.5±0.2 cm^{-1}) reported by Moore (1) is adopted as $\Delta_f H°(0\ K)$ for $Rn^+(g)$. The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ\ mol^{-1}$, which is derived from the 1973 CODATA fundamental constants (2). The uncertainty in the ionization limit is estimated to be ±0.2 cm^{-1} which corresponds to an uncertainty of ±0.002 $kJ\ mol^{-1}$ in the enthalpy of formation. Gurvich et al. (8) adopted the same ionization potential, but the use of slightly different value by Wagman et al. (10) results in a enthalpy of formation difference of 0.010 $kJ\ mol^{-1}$.

$\Delta_f H°(Rn^+, g, 298.15\ K)$ is obtained from $\Delta_f H°(Rn, g, 0\ K)$ by using IP(Rn) with JANAF (3) enthalpies $H°(0\ K)-H°(298.15\ K)$ for $Rn^+(g)$, Rn(r), and $e^-(r)$. $\Delta_r H°(Rn \rightarrow Rn^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (9). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights of Moore (4) is incomplete because no levels have been observed. Our calculations indicate that any reasonable method of filling in missing levels and cutting off the summation in the partition function (5) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the $^2P_{1/2}$ level; the next lowest level is estimated to be over 80000 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the ground state and the $^2P_{1/2}$ state, with the energy of the latter state taken from a more recent study by Moore (1). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (5).

The thermodynamic functions reported here agree with those of Green et al. (6), Hilsenrath et al. (7), and Gurvich et al. (8) except for two minor changes. First, the entropy differs by 0.1094 $J\ K^{-1}\ mol^{-1}$ because this table uses a standard state pressure of 1 bar, whereas the cited references used a pressure of 1 atm. Second, smaller differences arise from the use of different values for the fundamental constants, the relative ionic mass, and the position of the $^2P_{1/2}$ electronic level.

SULFUR (S) REFERENCE STATE A_r = 32.06

0 to 368.3	K	crystal, alpha
368.3 to 388.36	K	crystal, beta
388.36 to 882.117	K	liquid
above 882.117	K	ideal diatomic gas (see below)

The normal boiling point of sulfur at 1 atm, 717.824 K, is a secondary standard on the International Practical Temperature Scale of 1968. The vapor composition at this temperature is a mixture of several sulfur species, the predominant species being $S_8(g)$, $S_7(g)$, and $S_6(g)$. In our reference state for sulfur, we have arbitrarily chosen 0.5 $S_2(g)$ to be the gas phase species.

$S°(298.15\ K) = 33.028 \pm 0.050\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 368.3 \pm 0.3\ K\ (\alpha-\beta)$
$T_{fus} = 388.36 \pm 0.1\ K\ (\beta-\ell)$

$\Delta_f H°(0\ K) = 0.247\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 0.360\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 0.4004 \pm 0.0029\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 1.721 \pm 0.008\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of monoclinic sulfur at 298.15 K is calculated from that of orthorhombic sulfur by adding $\Delta_{trs}H°$ and the difference in enthalpy, H°(368.3) - H°(298.15 K), between orthorhobic and monoclinic sulfur.

Heat Capacity and Entropy

Experimentally determined heat capacity values for monclinic (β) sulfur have been reported by Eastman and McGavock (1, 64.83-376.16 K), West (2, 368-388 K), and Montgomery (3, 12.41-386.83 K). The thermochemical functions tabulated by Hultgren et al. (4) are based on the work of Eastman and McGavock (1) and West (2).

We adopt the heat capacity values tabulated (in 10 K increments) by Montgomery (3). The heat capacity values above T_{fus} = 388.36 K are obtained by linear extrapolation of the tabulated heat capacity values (3) above 360 K. Using S°(10 K) = 0.063 cal $K^{-1}\ mol^{-1}$ and integrating the heat capacity values, we calculate S°(298.15 K) = 7.893 cal $K^{-1}\ mol^{-1}$. The S°(10) value contains a contribution of 0.007 cal $K^{-1}\ mol^{-1}$ which is needed to make S°(S, cr, β, T) = S°(S, cr, α, T) + $\Delta_{trs}H°/T_{trs}$. Since both forms of sulfur are perfectly ordered crystals at 0 K (3), the S°(0 K) value should be zero, by definition. The contribution of 0.007 cal $K^{-1}\ mol^{-1}$ is arbitrarily added at 10 K although it could appear in any temperature region at or below 368.3 K. Part of this entropy may be in the region of the lambda anomaly at 198.3 K. This contribution is comparable to the uncertainty expected from this adiabatic calorimeter.

Phase Data

The α-β transition at 368.3 K is discussed on the orthorhombic sulfur table (5). The heat capacity data of Montgomery (3) did not support the transition at 374 K reported by West (2).

Montgomery (3) reported a lambda anomaly in the heat capacity of monoclinic sulfur with a peak at 198.3 K. The entropy change in the lambda anomaly was 0.052 ± 0.005 cal $K^{-1}\ mol^{-1}$, this was interpreted as due to the disordering of the structure of monoclinic sulfur on heating (7).

Fusion Data

The melting of sulfur has been studied by many workers. An excellent review by Meyer (6) summarizes these studies. In addition, Hultgren et al. (4) tabulated numerous enthalpy of melting determinations. We adopt the results obtained by Montgomery (3) via adiabatic calorimetry: T_{fus} = 388.36 ± 0.02 K and $\Delta_{fus}H°$ = 0.4128 ± 0.0006 kcal mol^{-1}. The only other precise study reported in the literature is that of West (2) who obtained $\Delta_{fus}H°$ = 0.41051 ± 0.0005 kcal mol^{-1} by adiabatic calorimetry.

$\Delta_{trs} H° = 0.4004 \pm 0.0029\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Experimentally determined heat capacity vlaues for orthorhombic (α) sulfur have been reported by Nernst (1, 23-202 K), Eastman and McGavock (2, 12.68-365.60 K), West (3, 2981-368 K), Mal'tsev and Demidenko (4, 53-305 K), Finke (5, 12-432 K), Montgomery (6, 12.34-360.99 K), and Paukov (7). The thermochemical functions tabulated by Hultgren et al. (8) are based primarily on the work of Eastman and McGavock (2) and unpublished work of Finke (5), the latter presumably being the preliminary results of Montgomery (6). The tentative values reported by CODATA (9) for S°(298.15 K) and H°(298.15 K) - H°(0 K) are based on Eastman and McGavock (2), Montgomery (6), and Paukov (7).

We adopt the heat capacity values tabulated (in 10 K increments) by Montgomery (6). Using S°(10) = 0.036 cal K^{-1} mol^{-1} and integrating the heat capacity values, we calculate S°(298.15 K) = 7.661 cal K^{-1} mol^{-1}, in agreement with CODATA (9). The heat capacity values above T_{trs} = 368.3 K are obtained by linear extrapolation of the tabulated values (6) above 340 K.

The various heat capacity studies are in reasonably good agreement. The values recommended by Eastman and McGavock (2), West (3), and Mal'tsev and Demidenko (4) agree with Montgomery (6) to within 0.5% except for the ranges 15-50 K (2) and 53-80 K (3). The smoothed value at 190 K reported by Mal'tsev and Demidenko (4) is undoubtedly a typographical error. The selected values of Hultgren et al. (8) agree within 0.5% with the data of Montgomery (6) except below 35 K.

Fusion Data

The orthorhomic-monoclinic (α-β) phase change has been studied by many workers. An excellent review by Meyer (10) summarizes these studies. We adopt the results obtained by Montgomery (6) via adiabatic calorimetry: T_{trs} = 368.3 ± 0.3 K and $\Delta_{trs}H°$ = 0.0957 ± 0.0007 kcal mol^{-1}. The only other precise study reported in the literature is that of West (3) who obtained $\Delta_{trs}H°$ = 0.0960 ± 0.0005 kcal mol^{-1} by adiabatic calorimetry. Other drop calorimetric (11, 12) and vapor pressure (13, 14) studies are much less precise with an uncertainty of ±5 cal mol^{-1} or greater.

Sublimation Data

Since the reference state of sulfur involves 0.5 $S_2(g)$ rather than S(g), we define the enthalpy of sublimation (at 298.15 K) of orthorhombic sulfur as the process S(cr, α) = 0.5 $S_2(g)$. Thus the enthalpy of sublimation of orthorhombic sulfur is one-half the enthalpy of formation of $S_2(g)$. Since the dominant gaseous sulfur species at room temperature is actually $S_8(g)$, the enthalpy of sublimation to the equilibrium gas is significantly smaller.

SULFUR (S) LIQUID A_r = 32.06

$S°(298.15\ K) = [36.825]\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 432.02 \pm 0.2\ K$

$T_{fus} = 388.36\ K$

$\Delta_f H°(298.15\ K) = [1.854]\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 0.0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 1.7272 \pm 0.0025\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of liquid sulfur at 298.15 K is calculated from that of monoclinic sulfur by adding $\Delta_{fus}H°$ and the difference, in enthalpy, H°(388.36 K) - H°(298.15 K), between monoclinic and liquid sulfur.

Heat Capacity and Entropy

The adopted heat capacity values are based on the studies by Montgomery (1, 405.79-433.31 K) and West (2, 373-678 K). Liquid sulfur undergoes a second order transition with a maximum reported at 432.02 ± 0.20 K (1) and 432.25 ± 0.30 K (2); this has been attributed to the polymerization of S_8 molecules (3). We adopt the tabulated heat capacity values of Montgomery (1) up to 434 K and those of West (2) above 434 K. The heat capacity is assumed to be constant at 7.568 cal K^{-1} mol^{-1} above 810 K. Below T_{fus} = 388.36 K, the heat capacity values are obtained by linear extrapolation using the slope of the values in the region T_{fus} to 420 K. The entropy is calculated in a manner similar to that used for the enthalpy of formation.

Vaporization Data

The normal boiling point of sulfur, T_{vap} = 717.824 K (1 atm) is a secondary reference on the International Practical Temperature Scale of 1968. At this temperature, equilibrium sulfur vapor contains monomeric and several polymeric sulfur species: $S_2(g)$ and S(g) predominate above 1000 K while $S_6(g)$, $S_7(g)$, and $S_8(g)$ dominate at T_{vap}.

Since our reference state for sulfur is arbitrarily defined to involve 0.5 $S_2(g)$ as the vapor species we calculate $\Delta_{vap}H°(T_{vap})$ = [10.839] k cal mol^{-1} for the process S(ℓ) = 0.5 $S_2(g)$. The brackets are used to indicate the arbitrary nature of this value.

Enthalpy of Formation

The enthalpy of formation is based on the dissociation energy for $S_2(g)$ as recommended by CODATA (1). The adopted value for $\Delta_f H°(S, g, 298.15\ K)$ is calculated using $D_0°(S_2)$ = 35216.4 ± 2.5 cm^{-1} (421.282 ± 0.03 kJ mol^{-1}) from the study of Ricks and Barrow (2).

The selected dissociation energy, obtained from precise spectroscopic measurements (2), is supported by additional studies on thermochemical cycles (3), photoionization (4, 5) and torsion-effusion measurements (6). Earlier measurements have been reviewed by Herzberg (7), Gaydon (8), Brewer (9), and Drowart and Goldfinger (3).

Heat Capacity and Entropy

The electronic levels for S(g) are given in the compilation by Moore (10, 11). Our calculations indicate that, except for the five levels lying below 23000 cm^{-1}, the inclusion of levels up to n = 10 has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of these levels; the fifth excited state lies at 52623.88 cm^{-1} above the ground state. Since the inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the lowest lying states (ϵ_i < 23000 cm^{-1}). The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative atomic mass and the fundeamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cutoff procedures (12). In fact, the inclusion of these higher excited states and consideration of various cutoff procedures leads to calculational differences in the Gibbs energy function of ~0.4 J K^{-1} mol^{-1} or greater at temperatures in excess of 11500 K.

The thermal functions at 298.15 K agree with CODATA recommendations (1) except for two minor differences. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a standard state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, an entropy difference of 0.004 J K^{-1} mol^{-1} arises due to the use of slightly different values for the fundamental constants.

SULFUR, ION (S^+) IDEAL GAS Mr = 32.05945

$IP(S^+, g) = 188200 \pm 100\ cm^{-1}$

$S°(298.15\ K) = 163.627 \pm 0.03\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1274.311 \pm 0.4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [1282.293]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	$\varepsilon_i\ cm^{-1}$	g_i
$^4S_{3/2}$	0	4
$^2D_{3/2}$	14853.0	4
$^2D_{5/2}$	14884.8	6
$^2P_{1/2}$	24524.9	2
$^2P_{3/2}$	24571.6	4

Enthalpy of Formation

$\Delta_f H°(S^+, g, 0\ K)$ is calculated from $\Delta_f H°(S, g, 0\ K)$ (1) using the spectroscopic value of $IP(S) = 83558.0 \pm 1\ cm^{-1}$ ($238.904 \pm 0.01\ kJ\ mol^{-1}$) from Moore (2). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, $1\ cm^{-1} = 0.01196266\ kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(S^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(S, g, 0\ K)$ by using IP(S) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for S(g), $S^+(g)$, and $e^-(g)$. $\Delta_f H°(S + S^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by $-6.197\ kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is approximately $79000\ cm^{-1}$ above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

SULFUR, ION (S^-) IDEAL GAS M_r = 32.06055

EA(S, g) = 2.077120 ± 0.000001 eV

$S°(298.15\ K)$ = 164.918 ± 0.001 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 74.325 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [70.180] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^2P_{3/2}$	0.0	4
$^2P_{1/2}$	483.54	2

Enthalpy of Formation

$\Delta_f H°(S^-, g, 0\ K)$ is calculated from $\Delta_f H°(S, g, 0\ K)$ (1) using the adopted electron affinity of EA(S) = 2.077120 ± 0.000001 eV (200.4100 ± 0.0001 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a tunable laser photodetachment threshold study (3). Additional information on $S^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(S^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(S, g, 0\ K)$ by using EA(S) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $S^-(g)$, S(g), and $e^-(g)$. $\Delta_r H°(S^- + S + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state and the fine-structure separation (483.54 ± 0.01 cm^{-1}) for $S^-(g)$ has been experimentally determined (3); a discussion of the relevant work is given by Hotop and Lineberger (2) and Massey (6). Lacking any experimental evidence as to the stability of any excited states, we assume no stable excited states exist.

Enthalpy of Formation

Herzberg (2) suggests a dissociation energy for SiS(g) of 6.6 eV. This result was derived from a spectroscopic analysis of the D-X and E-X band systems by Barrow and Jevons (4), Vago and Barrow (5), and Barrow (6). Robinson and Barrow (8) extended the work of Vago and Barrow (5) and arrived at a value of 147.4 ± 3.0 kcal mol^{-1} (6.39 eV). In this latter work, a graphical Birge-Sponer extrapolation was made using 28 vibrational levels of the E state. The highest level is quite near the convergence limit and thus only a short extrapolation is necessary. The extrapolation graphically indicates the absolute minimum and maximum to be 6.28 eV and 6.57 eV, respectively. This amounts to a range of maximum uncertainty of approximately 7 kcal mol^{-1}. The products of the dissociation must be $Si(^3p)$ and $S(^3p)$ but it is not certain as to which of the sublevels of the ^3p states are involved. This leads to an uncertainty of ± 1.2 kcal mol^{-1} (8). The result is in agreement with a rotational analysis of the $D^1\Pi$-$X^1\Sigma^+$ system by Lagerqvist, Nilheden, and Barrow (7) which led to a value of 6.47 eV (149.2 kcal mol^{-1}).

The value of the dissociation energy chosen is 147.4 ± 3.0 kcal mol^{-1}, based on the work by Robinson and Barrow (8). Gaydon (1) and Vedeneyev et al. (3) suggest a similar value, based on the work by Robinson and Barrow (8) and others. This value is also consistent with the tabulated dissociation energies of Gaydon (1) as far as trends which might be expected in the oxides, sulfides, and selenides of C, Si, Ge, Sn, and Pb. The resulting enthalpy of formation is $\Delta_f H°(0\ K) = 25.01 \pm 3.00$ kcal mol^{-1}.

Rosenqvist and Tungesvik (13) studied two reaction systems by a transportation method. By combining these two systems, the standard free energy of the reaction 2 Si(s) + S_2(g) = 2 SiS(g) was calculated. Using JANAF values (14) for Si(s) and S_2(g), $\Delta_f G°$ (1 atm) values for SiS(g) at 0 K and 300 K are 27.652 kcal mol^{-1} and 15.933 kcal mol^{-1}, respectively. These values are within the error range of the values in this tabulation.

Heat Capacity and Entropy

The spectroscopic constants, corrected for the natural abundances of Si and S, are from Hoeft (9), and Lagerqvist, Nilheden, and Barrow (7).

Herzberg (2) tabulates the $X^1\Sigma^+$, $D^1\Pi$, and E states and comments on unresolved bands at 16000-29000 cm^{-1}. The $a^3\Pi$ state is predicted by an interpolation of similar $a^3\Pi$-$X^1\Sigma^+$ splittings in the sulfides and oxides of C, Ge, Sn, (10, 11). The remaining states are deduced by a rotational analysis of the E-X system of SiS (7, 12). It is not known conclusively whether the F state is $^1\Pi$ or $^1\Delta$. The energy of the e and I states are upper bound estimates.

PREVIOUS: December 1971 (1 atm) CURRENT: December 1971 (1 bar)

STRONTIUM SULFIDE (SrS) CRYSTAL M_r = 119.68

$S°(298.15\ K) = 68.41 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = -467.4 \pm 17\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = -468.6 \pm 17\ kJ\ mol^{-1}$

Enthalpy of Formation

Sabatier (1) measured the enthalpy of solution of SrS in hydrochloric acid solution as $\Delta_r H(283.6\ K) = -26.9 \pm 1.0$ kcal mol^{-1} for SrS(cr) + 2 HCl(aq, 100 H_2O) + $SrCl_2$(aq, 100 H_2O) + H_2S(aq). We derive $\Delta_f H°$(SrS, cr, 298.15 K) = -113.1 ± 2.0 kcal mol^{-1} based on the following auxiliary data: $\Delta_f H°$(HCl•aq, 100 H_2O, 298.15 K) = -39.657 kcal mol^{-1} (3), $\Delta_f H°$(H_2S, aq, 298.15 K) = -9.5 kcal mol^{-1} (2), and $\Delta_f H°$($SrCl_2$•aq, 200 H_2O, 298.15 K) = -209.78 kcal mol^{-1} (3). The uncertainty reflects the correction to 298.15 K and the ambiguity of the exact solution composition. Mourlot (4) also measured the enthalpy of solution of SrS in hydrochloric acid solution as $\Delta_r H°$ = -27.1 ± 1.0 kcal mol^{-1} fromwhich we calculate $\Delta_f H°$(SrS, cr, 298.15 K) = -112.8 ± 2.0 kcal mol^{-1}, using the same auxiliary data.

Cater and Johnson (5) determined that SrS sublimes congruently and derived partial pressures of the various gaseous species Sr(g), S(g), and SrS(g) in an effusion and mass-spectrometric study. We analyze their data and the equilibrium study of Schenck and Hammerschmidt (6) below. Other mass-spectrometric studies of Berkowitz and Marquart (7) and Colin et al. (8) are also listed. The calculated 3rd law $\Delta_r H°$(298.15 K) may have an uncertainty of 0.5 kcal mol^{-1} since the JANAF Gibbs energy functions are partially based on the estimated $C_p°$ data (above 300 K).

The enthalpy of solution studies (1, 4) show wide disagreement from the mass spectrometric studies (5, 7, 8). Our experience tends to indicate that mass spectrometric experiments provide very good data on gas phase species for homogeneous reactions, but are not as reliable for condensed phases in heterogeneous reactions. A weighted average of the equilibrium and enthalpy of solution studies, $\Delta_f H°$(SrS, cr, 298.15 K) = -112.0 ± 4 kcal mol^{-1} is adopted in the tabulation.

A) SrS(cr) = Sr(g) + S(g)
B) SrS(cr) = SrS(g)
C) SrS(cr) + 2 SO_2(g) = $SrSO_4$(cr) + S_2(g)
D) SrS(cr) + 3 S(g) = Sr(g) + 2 S_2(g)

Heat Capacity and Entropy

King and Weller (10) measured the low temperature heat capacities from 53-296 K. Their smooth values are adopted in the tabulation. The entropy, S°(298.15 K) = 16.3 ± 0.2 cal K^{-1} mol^{-1}, is based on S°(51 K) = 1.59 cal K^{-1} mol^{-1} as extrapolated by King and Weller using Debye and Einstein functions (θ_D = 208, θ_E = 311). The $C_p°$ values above 300 K are estimated by graphical extrapolation combined with method B of Kubaschewski et al. (11).

Fusion Data

Literature melting data for SrS(cr) are not available. The value quoted by Mills (12) for the melting point, 2275 K, seems too low when compared to the alkaline earth oxide melting points (13).

Enthalpy of Formation

The adopted value for the enthalpy of formation, $\Delta_f H°(SrS, g, 298.15\ K) = 25.86 \pm 2$ kcal mol^{-1}, is based on the Knudsen mass spectrometric studies analyzed below. The three independent studies are in very good agreement and we have chosen the average of the measurements. Our value is in very good agreement with $\Delta_f H°(298.15\ K) = 25.0$ kcal mol^{-1} adopted by NBS (4) and is slightly greater than $\Delta_f H°(298.15\ K) = 24.1 \pm 4$ kcal mol^{-1} obtained by Mills (5) (using different Gibbs energy functions) in a recent critical compilation. Using auxiliary JANAF data (6) and a recommended value for $D_0^0(S_2, g) = 100.69 \pm 0.01$ kcal mol^{-1} (6), we calculate $D_0^0(SrS, g) = 78.8 \pm 2.0$ kcal mol^{-1}.

Heat Capacity and Entropy

Electronic levels (T_∞) and vibrational-rotational constants for the observed states are from the optical study of Barrow (7, 8). Other low-lying electronic states and their vibrational-rotational constants are estimated in isoconfigurational groups by analogy with SrO (6) and from trends observed in the known states of the other alkaline-earth oxides and sulfides (6). Uncertainty in the energy and constants for the estimated states may contribute as much as 2-3 cal K^{-1} mol^{-1} to S° at 3000 K. The molecular constants have been corrected to the natural isotopic abundances. The thermodynamic functions are calculated using first-order anharmonic corrections to Q_r^i and Q_v^i in the partition function $Q = Q_t \Sigma_i Q_r^i Q_v^i g_i \exp(-c_2\epsilon_i/T)$.

Enthalpy of Formation

The adopted enthalpy of formation is that selected by CODATA (1). The value was calculated from measurments of the equilibrium $H_2S(g) = H_2(g) \pm 0.05\ S_2(g)$ reported by Randall and Bichowsky (2), Preuner (3), and Preuner and Schupp (4), and from measurements of the partial pressure of $S_2(g)$ over sulfur reported by Drowart, Goldfinger, Detry, Rickert, and Keller (5).

The dissociation energy, $D_0^0 = 35216.4 \pm 2.5\ cm^{-1}$ (100.689 ± 0.021 kcal mol^{-1}) is from the spectroscopic study by Ricks and Barrow (12).

Heat Capacity and Entropy

The thermal functions above 600 K are calculated using the program of McBride and Gordon (6). The contribution of vibrational anharmonicity, rotation-vibration interaction, and centrifugal stretching are calculated via the procedures given by Pennington and Kobe (7). The electronic and molecular constant data in the above table are that summarized by Rosen (8) and Suchard (9) with the exception that the position of the $a^1\Delta_g$ state at $4700 \pm 800\ cm^{-1}$ is from the more recent absorption study by Carleer and Colin (10).

The thermal functions below 600 K are calculated by direct summation over vibrational-rotational energy levels of the ground state (including the proper treatment of the splitting of this level, i.e. $\alpha = -0.0066\ cm^{-1}$ and $\lambda = 11.84\ cm^{-1}$, and three excited states. We performed the direct summation with a program written by W. H. Evans of the U. S. Bureau of Standards. The direct summation results are not extended to temperatures above 600 K since the enrgy levels derived from the reported vibrational-rotational constants do not converge to the dissociation energy. For these higher temperatures, the program of McBride and Gordon is used, as in the case of gaseous O_2 (11).

The value of S°(298.15 K) agrees exactly with the CODATA recommended value (1). The uncertainty in S°(298.15 K) is due to uncertainties in fundamental constants, the atomic weight, and the ground state molecular constants. The contributions of the excited states above $22000\ cm^{-1}$ do not affect the thermal functions below 2000 K but do become significant at higher temperatures. However, these states are not included for two reasons. First, the electronic and molecular constants are not all well-defined. Second, many of these levels have a sufficiently shallow potential energy well, which would lead to unreasonably large heat capacity values at high temperatures.

PREVIOUS: September 1977 (1 atm) CURRENT: September 1977 (1 bar)

$S°(298.15\ K) = [80.333 \pm 4.2]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1363\ K$

$\Delta_f H°(0\ K)$ = Unknown

$\Delta_f H°(298.15\ K) = -213.384 \pm 20.9\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [8.4 \pm 4.2]\ kJ\ mol^{-1}$

Enthalpy of Formation

Rocquet and Ancey-Haret (1) determined the enthalpy of reaction for the following:

$SiS_2(cr) + 6\ HF(20\%) + H_2SiF_6(<20\%HF) + 2\ H_2S(g)$, $\Delta_r H°(298.15\ K) = -72.8 \pm 2.2\ kcal\ mol^{-1}$.

A related system was examined by Kilday and Prosen (2):

SiO_2 (α-quartz) + 6 HF(20.0%) + H_2SiF_6(<20.0% HF) + 2 $H_2O(\ell)$, $\Delta_r H°(298.15\ K) = -32.65 \pm 0.02\ kcal\ mol^{-1}$.

Combining these two systems mathematically yields approximately the following:

SiO_2 (α-quartz) + 2 $H_2S(g)$ + $SiS_2(cr)$ + 2 $H_2O(\ell)$, $\Delta_r H°(298.15\ K) = 40.2 \pm 3.0\ kcal\ mol^{-1}$.

Using JANAF (4) and NBS (8) auxiliary data, $\Delta_f H°(SiS_2, cr, 298.15\ K)$ is equal to $-51.1 \pm 3.0\ kcal\ mol^{-1}$. In addition to the normal experimental error in each study, another source of error arises from the saturated solution of H_2S in the former work but not the latter.

Emmons and Theisen (3) measured the equilibrium vapor pressures for the system 1/2 $SiS_2(cr)$ + 1/2 Si(cr) + SiS(g) and presented graphically log P(SiS) vs 1/T data. Using these data, a 3rd law analysis yields $\Delta_r H°(298.15\ K) = 55.27\ kcal\ mol^{-1}$ with a drift of $5.1 \pm 1.2\ cal\ K^{-1}\ mol^{-1}$. A 2nd law analysis yields $\Delta_r H°(298.15\ K) = 50.09\ kcal\ mol^{-1}$. These results lead, respectively, to $\Delta_f H°(SiS_2, cr, 298.15\ K) = -59.84\ kcal\ mol^{-1}$ and $\Delta_f H°(SiS_2, cr, 298.15\ K) = -49.53\ kcal\ mol^{-1}$, with JANAF (4) auxiliary data.

Fruehan and Turkdogan (5) studied the same reaction by means of a silica Knudsen cell-mass specrometer combination. A 2nd law analysis of their graphical data for two different orifice sizes yields values of $\Delta_r H°(298.15\ K) = 53.74\ kcal\ mol^{-1}$ and 46.9 $kcal\ mol^{-1}$. Again, using JANAF auxiliary data (4), $\Delta_f H°(SiS_2, cr, 298.15\ K) = -56.83\ kcal\ mol^{-1}$ and $-42.33\ kcal\ mol^{-1}$ respectively, or an average value of $-49.58\ kcal\ mol^{-1}$.

The value chosen for the enthalpy of formation is $\Delta_f H°(SiS_2, cr, 298.15\ K) = -51.0 \pm 5.0\ kcal\ mol$. This value is a rounded value of the work of Rocquet and Ancey-Maret (1). Berezknoi (7) references five reported values for the enthalpy of formation (through 1954) and recommended the work of Rocquet and Ancey-Maret (1) as the most accurate. Kubaschewski et al. (8) in their compilation of enthlpies of formation (through 1965) also rely on the data from Rocquet and Ancey-Maret (1).

Heat Capacity and Entropy

The heat capacity is assumed to be given by the relation $C_p°/cal\ K^{-1}\ mol^{-1} = 17.72 \pm 2.96 \times 10^{-3}T$ for $298 \leq T \leq 1363\ K$. This relation was suggested by Rasch (9) following procedures described by Kubaschewski et al. (8). This equation was linearly extrapolated to yield $C_p°$ values up to 2000 K. Kubaschewski et al. (8) suggested $S°(298.15\ K) = 19.2\ cal\ K^{-1}\ mol^{-1}$.

Fusion Data

The melting point of $SiS_2(cr)$ was determined to be $T_{fus} = 1363\ K$ by Tiede and Thimann (10). $\Delta_{fus}H°$ was estimated, based on the entropy of melting for SiO_2 (quartz and cristobolite).

SILICON SULFIDE (SiS_2) LIQUID M_r = 92.2055

$S°(298.15\ K) = [84.687]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1363\ K$

$\Delta_f H°(298.15\ K) = [-206.924]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = [8.4 \pm 4.2]\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(\ell, 298.15\ K)$ is calculated from $\Delta_f H°(cr, 298.15\ K)$ by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1363\ K)-H°(298.15\ K)$, between the crystal and the liquid.

Heat Capacity and Entropy

Using methods suggested by Kubaschewski et al. (1), the heat capacity of the liquid is assumed to be a constant 21.75 cal K^{-1} mol^{-1} from 1363 K to 1403 K. $S°(\ell, 298.15\ K)$ is calculated in a manner similar to that used for the enthalpy of formation. A glass transition is assumed at 900 K.

Fusion Data

See the crystal table for details.

SULFUR (S_3) IDEAL GAS M_r = 96.18

$S°(298.15\ K) = [269.5 \pm 4]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [141.5 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation for each vapor phase sulfur species S_3 to S_7 is calculated by a third law calculation using the thermal functions described below and assuming that the vapor pressure data given by Hultgren et al. (1) and Rau et al. (2) are correct. These values for the enthalpy of formation are dependent on the somewhat arbitrary thermal functions adopted for the polyatomic sulfur gases.

Heat Capacity and Entropy

The thermal functions for the polyatomic species, S_3 to S_7, are estimated following the suggestion of Rau et al. (2). Using thermal functions calculated for S(g), S_2(g), and S_8(g), the heat capacity values for the remaining species were calculated by Rau et al. assuming that the vibrational heat capacity per degree of freedom is the same for all sulfur polyatomic species. The resulting heat capacity equations are given by Rau et al. (2).

The use of the procedure of Rau et al. (2) leads to a set of thermal functions and associated enthalpies of formation which reproduce the observed sulfur vapor pressure data. That is, the sum of the calculated partial pressures of all eight sulfur vapor species, S_1(g) to S_8(g), does closely reproduce the observed vapor pressure. [A difference between the calculated boiling point (at 1 atm) and the secondary reference temperature boiling point is due to the difference between the ideal gas calculation and the real observed value.]

The thermal fuctions for S_8(g) were calculated (3) by adjusting the low valued vibrational frequencies such that S(298.15 K) and $\Delta_f H°$(298.15 K) values could be found which reproduced the partial pressure of the octamer. The entropy of S_2(g) is well-known (3), being based on reliable data and sound statistical mechanical calculations.

The thermal functions which would result from the use of the available structural and vibrational inbformation for the remaining polyatomic species, are biased in the same way as for S_8(g). Some of the necessary information is derived from condensed phase spectra (rather than gas phase spectra). as with the octamer, the low-valued vibrational frequencies (and possibly the structure) may need to be adjusted. In any event, the use of the existing spectroscopic data (unaltered) leads to calculated entropies which are unreasonable when used in a 3rd law analysis to mesh in the vapor pressure with these thermal functions.

PREVIOUS: December 1977 (1 atm) CURRENT: September 1977 (1 bar)

SULFUR (S_4) IDEAL GAS M_r = 128.24

$S°(298.15\ K) = [310.6 \pm 4]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [145.8 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation for each vapor phase sulfur species S_3 to S_7 is calculated by a third law calculation using the thermal functions described below and assuming that the vapor pressure data given by Hultgren et al. (1) and Rau et al. (2) are correct. These values for the enthalpy of formation are dependent on the somewhat arbitrary thermal functions adopted for the polyatomic sulfur gases.

Heat Capacity and Entropy

The thermal functions for the polyatomic species, S_3 to S_7, are estimated following the suggestion of Rau et al. (2). Using thermal functions calculated for S(g), S_2(g), and S_8(g), the heat capacity values for the remaining species were calculated by Rau et al. assuming that the vibrational heat capacity per degree of freedom is the same for all sulfur polyatomic species. The resulting heat capacity equations are given by Rau et al. (2).

The use of the procedure of Rau et al. (2) leads to a set of thermal functions and associated enthalpies of formation which reproduce the observed sulfur vapor pressure data. That is, the sum of the calculated partial pressures of all eight sulfur vapor species, S_1(g) to S_8(g), does closely reproduce the observed vapor pressure. [A difference between the calculated boiling point (at 1 atm) and the secondary reference temperature boiling point is due to the difference between the ideal gas calculation and the real observed value.]

The thermal fuctions for S_8(g) were calculated (3) by adjusting the low valued vibrational frequencies such that S(298.15 K) and $\Delta_f H°$(298.15 K) values could be found which reproduced the partial pressure of the octamer. The entropy of S_2(g) is well-known (3), being based on reliable data and sound statistical mechanical calculations.

The thermal functions which would result from the use of the available structural and vibrational inbformation for the remaining polyatomic species, are biased in the same way as for S_8(g). Some of the necessary information is derived from condensed phase spectra (rather than gas phase spectra). As with the octamer, the low-valued vibrational frequencies (and possibly the structure) may need to be adjusted. In any event, the use of the existing spectroscopic data (unaltered) leads to calculated entropies which are unreasonable when used in a 3rd law analysis to mesh in the vapor pressure with these thermal functions.

PREVIOUS: September 1977 (1 atm) CURRENT: September 1977 (1 bar)

SULFUR (S_5) IDEAL GAS M_r = 160.30

$S°(298.15\ K) = [308.6 \pm 4]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [109.4 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation for each vapor phase sulfur species S_3 to S_7 is calculated by a third law calculation using the thermal functions described below and assuming that the vapor pressure data given by Hultgren et al. (1) and Rau et al. (2) are correct. These values for the enthalpy of formation are dependent on the somewhat arbitrary thermal functions adopted for the polyatomic sulfur gases.

Heat Capacity and Entropy

The thermal functions for the polyatomic species, S_3 to S_7, are estimated following the suggestion of Rau et al. (2). Using thermal functions calculated for S(g), S_2(g), and S_8(g), the heat capacity values for the remaining species were calculated by Rau et al. assuming that the vibrational heat capacity per degree of freedom is the same for all sulfur polyatomic species. The resulting heat capacity equations are given by Rau et al. (2).

The use of the procedure of Rau et al. (2) leads to a set of thermal functions and associated enthalpies of formation which reproduce the observed sulfur vapor pressure data. That is, the sum of the calculated partial pressures of all eight sulfur vapor species, S_1(g) to S_8(g), does closely reproduce the observed vapor pressure. [A difference between the calculated boiling point (at 1 atm) and the secondary reference temperature boiling point is due to the difference between the ideal gas calculation and the real observed value.]

The thermal fuctions for S_8(g) were calculated (3) by adjusting the low valued vibrational frequencies such that S(298.15 K) and $\Delta_f H°$(298.15 K) values could be found which reproduced the partial pressure of the octamer. The entropy of S_2(g) is well-known (3), being based on reliable data and sound statistical mechanical calculations.

The thermal functions which would result from the use of the available structural and vibrational inbformation for the remaining polyatomic species, are biased in the same way as for S_8(g). Some of the necessary information is derived from condensed phase spectra (rather than gas phase spectra). As with the octamer, the low-valued vibrational frequencies (and possibly the structure) may need to be adjusted. In any event, the use of the existing spectroscopic data (unaltered) leads to calculated entropies which are unreasonable when used in a 3rd law analysis to mesh in the vapor pressure with these thermal functions.

PREVIOUS: September 1977 (1 atm) CURRENT: September 1977 (1 bar)

SULFUR (S_6) IDEAL GAS M_r = 160.30

$S°(298.15\ K) = [354.1 \pm 4]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [101.9 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation for each vapor phase sulfur species S_3 to S_7 is calculated by a third law calculation using the thermal functions described below and assuming that the vapor pressure data given by Hultgren et al. (1) and Rau et al. (2) are correct. These values for the enthalpy of formation are dependent on the somewhat arbitrary thermal functions adopted for the polyatomic sulfur gases.

Heat Capacity and Entropy

The thermal functions for the polyatomic species, S_3 to S_7, are estimated following the suggestion of Rau et al. (2). Using thermal functions calculated for S(g), S_2(g), and S_8(g), the heat capacity values for the remaining species were calculated by Rau et al. assuming that the vibrational heat capacity per degree of freedom is the same for all sulfur polyatomic species. The resulting heat capacity equations are given by Rau et al. (2).

The use of the procedure of Rau et al. (2) leads to a set of thermal functions and associated enthalpies of formation which reproduce the observed sulfur vapor pressure data. That is, the sum of the calculated partial pressures of all eight sulfur vapor species, S_1(g) to S_8(g), does closely reproduce the observed vapor pressure. [A difference between the calculated boiling point (at 1 atm) and the secondary reference temperature boiling point is due to the difference between the ideal gas calculation and the real observed value.]

The thermal fuctions for S_8(g) were calculated (3) by adjusting the low valued vibrational frequencies such that S(298.15 K) and $\Delta_f H°$(298.15 K) values could be found which reproduced the partial pressure of the octamer. The entropy of S_2(g) is well-known (3), being based on reliable data and sound statistical mechanical calculations.

The thermal functions which would result from the use of the available structural and vibrational inbformation for the remaining polyatomic species, are biased in the same way as for S_8(g). Some of the necessary information is derived from condensed phase spectra (rather than gas phase spectra). As with the octamer, the low-valued vibrational frequencies (and possibly the structure) may need to be adjusted. In any event, the use of the existing spectroscopic data (unaltered) leads to calculated entropies which are unreasonable when used in a 3rd law analysis to mesh in the vapor pressure with these thermal functions.

PREVIOUS: September 1977 (1 atm) *CURRENT:* September 1977 (1 bar)

SULFUR (S_7) IDEAL GAS M_r = 224.42

$S°(298.15\ K) = [407.7 \pm 4]\ J\ K^{-1}\ mol^{-1}$ $\Delta_f H°(298.15\ K) = [113.7 \pm 8]\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation for each vapor phase sulfur species S_3 to S_7 is calculated by a third law calculation using the thermal functions described below and assuming that the vapor pressure data given by Hultgren et al. (1) and Rau et al. (2) are correct. These values for the enthalpy of formation are dependent on the somewhat arbitrary thermal functions adopted for the polyatomic sulfur gases.

Heat Capacity and Entropy

The thermal functions for the polyatomic species, S_3 to S_7, are estimated following the suggestion of Rau et al. (2). Using thermal functions calculated for S(g), S_2(g), and S_8(g), the heat capacity values for the remaining species were calculated by Rau et al. assuming that the vibrational heat capacity per degree of freedom is the same for all sulfur polyatomic species. The resulting heat capacity equations are given by Rau et al. (2).

The use of the procedure of Rau et al. (2) leads to a set of thermal functions and associated enthalpies of formation which reproduce the observed sulfur vapor pressure data. That is, the sum of the calculated partial pressures of all eight sulfur vapor species, S_1(g) to S_8(g), does closely reproduce the observed vapor pressure. [A difference between the calculated boiling point (at 1 atm) and the secondary reference temperature boiling point is due to the difference between the ideal gas calculation and the real observed value.]

The thermal fuctions for S_8(g) were calculated (3) by adjusting the low valued vibrational frequencies such that S(298.15 K) and $\Delta_f H°$(298.15 K) values could be found which reproduced the partial pressure of the octamer. The entropy of S_2(g) is well-known (3), being based on reliable data and sound statistical mechanical calculations.

The thermal functions which would result from the use of the available structural and vibrational inbformation for the remaining polyatomic species, are biased in the same way as for S_8(g). Some of the necessary information is derived from condensed phase spectra (rather than gas phase spectra). As with the octamer, the low-valued vibrational frequencies (and possibly the structure) may need to be adjusted. In any event, the use of the existing spectroscopic data (unaltered) leads to calculated entropies which are unreasonable when used in a 3rd law analysis to mesh in the vapor pressure with these thermal functions.

SULFUR (S_8) IDEAL GAS M_r = 256.48

$S°(298.15\ K) = 430.31 \pm 0.05\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 104.39 \pm 0.63\ kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K) = 100.42 \pm 0.63\ kJ\ mol^{-1}$

Vibrational Frequencies and Degeneracies

ν, cm^{-1}	ν, cm^{-1}	ν, cm^{-1}
475(1)	475(2)	243(1)
218(1)	152(2)	437(2)
471(2)	56(2)	248(2)
191(2)	411(1)	

Ground State Quantum Weight: [1] $\sigma = 8$
Point Group: D_{4d}
Bond Distance: S-S = 2.059 ± 0.002 Å
Bond Angle: S-S-S = 107.9 ± 0.6°
Product of the Moments of Inertia: $I_A I_B I_C = 3.90326 \times 10^{-111}\ g^3\ cm^6$

Enthalpy of Formation

The vapor pressure of S(cr) has been measured by many investigators. Using the seven more recent vapor pressure data, the respective enthalpy of sublimation was calculated by both the 2nd and 3rd law methods. The values obtained are tabulated as follows:

Source	T/K	$\Delta_{sub}H°(298.15)$, kcal mol^{-1} 3rd Law	2nd Law
West-Menzies (1)	376.6 - 448.8	24.29	21.29
Neumann (2)	332.6 - 362.1	24.35	26.47
Fouretier (3)	304.1 - 351.6	24.36	24.10
Taillade (4)	303.6 - 352.5	24.29	24.87
Bradley (5)	288.3 - 305.7	24.29	23.80
Magee (6)	331.9 - 368.0	24.11	24.44
	332.7 - 367.4	24.12	23.88
Briske (7)	273.2 - 313.2	24.28	24.00

Due to the presence of $S_6(g)$ in $S_8(g)$, the measured total pressures were corrected to give the parttial pressures of $S_8(g)$ for the first five sets of vapor pressure data, according to Scott (8). However, the magnitude of the correction is only 0.1 - 0.2 kcal mol^{-1}. The adopted value is the weighted average of both the 2nd and 3rd law values.

Heat Capacity and Entropy

The vibrational frequencies were taken from Scott, McCullough and Kruse (9). Four of the eighteen frequencies, i.e. 86(2) and 218(2) cm^{-1}, were changed to 56(2) and 248 (2) cm^{-1}, respectively, as suggested by Scott (10). The molecular structure and bond distance and angle were reported by Donohur, Caron and Goldish (11). The principle moments of inertia are: $I_A = I_B = 1.28594 \times 10^{-37}$ and $I_C = 2.36042 \times 10^{-37}\ g\ cm^2$.

$S°(298.15\ K) = 18.820 \pm 0.04\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1685 \pm 3\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 50.2 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

Low temperature heat capacities are based on the precise data of Flubacher et al. (8-300 K, 1). The entropy is obtained from the heat capacity using $S°(8\ K) = 0.0003\ cal\ K^{-1}\ mol^{-1}$. The selected values are consistent with recent data of Keesom and Seidel (1.2-4.2 K, 2) and Kalishevich et al. (60-300 K, 3). Earlier data have been reviewed by Hultgren et al. (10).

High temperature studies are summarized below along with the pertinent low temperatures studies. The selected heat capacities above 300 K are obtained from a Shomate plot of the adopted low temperature heat capacities and the enthalpies reported or derived from the work of Dennison (5), Kantor et al. (6), Olette (7), Serebrennikov and Gel'd (8) and Magnus (9). Discrepancies are apparent in the enthalpy data, particularly in the range of 370-1100 K where only the recent study of Dennison (5) made use of a high purity sample. Enthalpies from Dennison (5) join most smoothly with the low temperature heat capacity but deviate increasingly at higher temperatures, being 1-2% lower than the other measurements above 1000 K. The selected functions agree with Dennison (5) below 600 K, with Magnus (1) from 600 to 1200 K, and with Kantor et al. (6) above 1200 K. The resulting heat capacities are slightly different from those selected by Hultgren, et al. (10); the latter are 0.07 cal K^{-1} mol^{-1} higher at 800 K and 0.21 cal K^{-1} mol^{-1} lower at the melting point.

Source	Method	Quantity Reported	T/K	Sample
(1)	Calorimetry	Cp°	7.7 - 300	Single crystal, 3mm pieces, Resistance (300 K) = 100 ohm cm, Carrier Concentration $\leq 10^{15}\ cm^{-3}$
(2)	Calorimetry	Specific Heat	1.2 - 4.2	
(3)	Calorimetry	Cp°	60 - 300	99.999%
(4)	Temperature Modulation	Cp°	300 - 900	Resistance (300 K) = 0.027 ohm cm, Carrier Concentration = $10^{19}\ cm^{-3}$
(5)	Drop Calorimetry	Specific Heat	273 - 1373	Resistance (300 K) = 107 ohm cm
(6)	Drop Calorimetry	Enthalpy Equation	1148 - 1685	"Highly purified"
(7)	Drop Calorimetry	Specific Enthalpy	1467 - 1685	99.99%
(8)	Drop Calorimetry	Specific Enthalpy	302 - 1556	99.3%
(9)	Drop Calorimetry	Specific Enthalpy	372 - 1175	99.2%

Fusion Data

PREVIOUS: December 1962 CURRENT: December 1966

$S°(298.15\ K) = [44.460]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1685 \pm 3\ K$

$\Delta_f H°(298.15\ K) = [48.470]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 50.2 \pm 0.4\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation, $\Delta_f H°(Si, \ell, 298.15\ K)$ is calculated from that of the crystal by adding $\Delta_{fus} H°$ and the difference in enthalpy, $H°(1685\ K) - H°(298.15\ K)$, between the crystal and liquid.

Heat Capacity and Entropy

Enthalpy data for high purity samples in quartz or vitreous silica capsules have been reported for the range 1698-1915 K by Kantor et al. (1) and for the range 1686-1825 K by Olette (2). *Due to the limited temperature range and the experimental* uncertainty, the data do not appear to justify more than a constant heat capacity. A value of 6.5 cal $K^{-1}\ mol^{-1}$ is selected, intermediate between the values of 6.75 and 6.15 obtained from separate experiments.

The entropy is calculated in a manner analogous to that used for the enthalpy of formation.

Fusion Data

Modern determinations of the melting point range from 1683 ± 1 to 1690 ± 4 K, the former from the specific volume study of Lucas and Urbain (3) and the later from the enthalpy study of Kantor et al. (1). The selected value, T_{fus} = 1685 K, is taken from Hultgren et al. (4), who have reviewed the melting data.

The enthalpy of melting is calculated from the selected enthalpy of the crystal and the liquid enthalpy measurements of Kantor et al. (1) and Olette (2), who reported comparable values of $\Delta_{fus} H° = 11.95 \pm 0.18$ and 12.095 ± 0.1 kcal mol^{-1}, respectively.

Vaporization Data

T_{vap} is calculated as the temperature for which $\Delta_r G° = 0$ for $Si(\ell) = Si(g)$. $\Delta_{vap} H°$ is calculated as the difference between $\Delta_f H°(g)$ and $\Delta_f H°(\ell)$ at T_{vap}. The normal boiling for the equilibrium vapor is calculated as the temperature at which Si, Si_2, and Si_3 attain a total pressure of 1 atm; the vapor containing 92.1%, 7.0% and 0.9% (mole) of monomer, dimer, and trimer, repectively. *tetramer and high polymers, which are ignored in this calculation, are probably negligible at this temperature (~ 3490 K).*

Enthalpy of Formation

The enthalpy of formation of silicon gas is chosen to be the value recommended by CODATA (1). This value was calculated from the sublimation and decomposition measurements of Davis et al. (1848-2003 K, 2), Grievison and Alcock(1940-2054 K, 3), Drowart et al. (4), Gulbranson et al. (1373-1623 K, 5), Batdorf and Smits (1493-1601 K, 6), and Zenbov et al. (7).

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (8, 9), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels (for n<11) and cutting off the summation in the partition function (10) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than those listed above; the next excited state is approximately 33326 cm^{-1} above the ground state. Although we list only a few levels, all levels given by Moore (8, 9) and estimated levels (for n<11) are considered in the calculation. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states (for n>10) and use of different fill and cutoff procedures (10).

The thermal functions at 298.15 K closely agree with the recent CODATA recommendations (1) except for two minor changes. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table used a reference pressure of 1 bar, wheras CODATA recommendations are based on 1 atm. Second, the entropy differs by ~0.001 J K^{-1} mol^{-1} due to the use of slightly different values for the fundamental constants.

SILICON, ION (Si^+) IDEAL GAS M_r = 28.08495

$IP(Si^+, g)$ = 131838.4 ± 0.1 cm^{-1}
$S°(298.15\ K)$ = 163.426 ± 0.02 $JK^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K)$ = 1232.2 ± 4 $kJ\ mol^{-1}$
$\Delta_f H°(298.15\ K)$ = [1242.505] $kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	$n_i\ cm^{-1}$	g_i
^2P	0	2
$^2P_{1/2}$	287.32	4
$^2P_{3/2}$	42824.35	4
$^4P_{1/2}$	42932.68	6
$^4P_{3/2}$	43107.97	4
$^4P_{5/2}$		

Enthalpy of Formation

$\Delta_f H°(Si^+, g, 0\ K)$ is calculated from $\Delta_f H°(Si, g, 0\ K)$ (1) using the spectroscopic value of IP(Si) = 65747.5 ± 0.6 cm^{-1} (786.515 ± 0.001 $kJ\ mol^{-1}$) from Moore (2, 6). The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ\ cm^{-1}$, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Si^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Si, g, 0\ K)$ by using IP(Si) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Si(g), $Si^+(g)$, and $e^-(g)$. $\Delta_f H°(Si + Si^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first four excited states; the next excited state is 55309.61 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in $S°(298.15\ K)$ is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

PREVIOUS: December 1971 (1 atm) CURRENT: March 1983 (1 bar)

EA(Si, g) = 1.385 ± 0.005 eV

$S°(298.15\ K)$ = 161.977 ± 0.001 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 312.04 ± 3 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [308.819] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ϵ_i, cm^{-1}	g_i
$^4S_{3/2}$	0.0	4
^2D	6952	10
^2P	10937	6

Enthalpy of Formation

$\Delta_f H°(Si^-, g, 0\ K)$ is calculated from $\Delta_f H°(Si, g, 0\ K)$ (1) using the adopted electron affinity of EA(Si) = 1.385 ± 0.005 eV (133.631 ± 0.482 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Si^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Si^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Si, g, 0\ K)$ by using EA(Si) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Si^-(g)$, Si(g), and $e^-(g)$. $\Delta_r H°(Si^- \rightarrow Si + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

Electronic energy levels are from the laser photodetachment electron spectrometry study of Kasdan et al. (3). These workers found that the $Si^-(^2D)$ and $Si^-(^2P)$ states have binding energies of 0.523 ± 0.005 eV and 0.029 ± 0.005 eV, respectively, relative to ground state $Si(^3P_0)$. The electronic energies of 6952 cm^{-1} and 10937 cm^{-1} are the difference in binding energy between ground and excited states. We neglect the spin-orbit splitting of the ^2D and ^2P states; its effect is negligible.

Enthalpy of Formation

The selected value is based on the spectroscopic and equilibrium data summarized below. Verma and Warsop (1) concluded from analysis of the absorption spectra that $D_0^0 = 70 \pm 4$ kcal mol^{-1}. Predissociation of the H state suggested the upper limit $D_0^0 \leq 74.0$, while linear Birge-Sponer extrapolations of the H and K states gave 78.4 and 68.9 kcal mol^{-1} for the ground state. By assuming that the true extrapolation would not reduce the linear extrapolation for the H state by more than half, i.e. from 26 to 13 kcal mol^{-1}, the authors arrived at the lower limit of $D_0^0 \geq 65.5$ for the ground state.

Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite (2), SiC-silicon (3) and boron-carbon-silicon (4). Third law analysis of the partial pressures of Si_2 and Si over the three systems yields D_0^0 values of 73.3, 74.3 and 70.4 kcal mol^{-1}, which are in good agreement with the spectroscopic values. The selected value, $\Delta_f H°(298.15\ K) = 141 \pm 3$ kcal mol^{-1}, corresponds to $D_0^0 = 73.0$ kcal mol^{-1}.

Heat Capacity and Entropy

Vibrational and rotational constants are those obtained by Verma and Warsop (1) through combination of their data for the H-X system with those of Douglas (5). Observation of the same H-X system in matrix isolation by Weltner and McLeod (6) confirms that the lower state is the ground state. Comparison with the isoelectronic molecules C_2, BN, BeO and MgO (7, 8, 9, 10) suggest that there are several possible low-lying excited states in Si_2. Tentative estimates for these levels are given above, based on this comparison and on the observed states (1, 5). These estimates are relatively uncertain and probably yield an upper limit for the entropy at temperatures where Si_2 is significant. A probable lower limit may be obtained by increasing the two $^3\Pi$ states by 8000 cm^{-1} and omitting the other estimated levels. This would reduce the entropy by 1.7 cal K^{-1} mol^{-1} at 2000 K, corresponding to a change of 3.4 kcal mol^{-1} in $\Delta_r H°$ values based on equilibrium data.

Rotational Constant: B_0 = [0.059282] cm^{-1}

Enthalpy of Formation

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the systems SiC-graphite (1) and SiC-silicon (2). Third law analysis of the partial pressures of Si_3 and Si yields the values 154.0 and 149.9 kcal mol^{-1}. Both drifts suggest that the entropy may be lower than the tabulated values. It is unlikely that the entropy is in error by more than 5 cal K^{-1} mol^{-1} so that most of the drift is inherent in the data. The adopted value of $\Delta_f H°(298.15\ K)$ = 152 ± 10 kcal mol^{-1} includes allowance for an error of up to 5 cal K^{-1} mol^{-1}.

*For reaction $Si_3(g) = 3\ Si(g)$

Heat Capacity and Entropy

Weltner and McLeod (3) observed an absorption band near 4660 Å in matrix isolation studies. Their tenative assignment of *this band as the* $^3\Sigma_u^- \leftarrow {}^3\Sigma_g^-$ *transition of* Si_3 is adopted here. A $^1\Pi_u$ state is assumed at 18000 cm^{-1}, which is 7000 and 2000 cm^{-1} below the analogous levels[3] for C_3 and C_2Si. Also a $^3\Pi_u$ level is assumed at 10000 cm^{-1}, presumably arising from the same molecular orbital configuration as the $^1\Pi_u$ state. The molecule is assumed to be linear with a bond distance equal to that in Si_2. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 2.16 \times 10^5$ and $k\sigma/l^2 = 0.11 \times 10^5$ dyn cm^{-1}. The stretching force constant is obtained from Si_2, while the bending force constant is based on C_2Si and the $^1\Pi_u$ excited state[3] of C_3.

PREVIOUS: December 1970 (1 atm) CURRENT: September 1983 (1 bar)

STRONTIUM (α-Sr) CRYSTAL A_r = 87.62

Pearson Notation: CF4

$S°(298.15\ K) = 55.69 \pm 0.1\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha\rightarrow\beta) = 820 \pm 8\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{trs} H°(820\ K) = 0.8368 \pm 0.17\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted heat capacities are derived from the heat capacity (1, 2) and enthalpy (2) data by fitting the experimental data with orthogonal polynomials over selected overlapping temperature intervals. The temperature region of 1-9 K is described by the equation: $C_p° = 3.281 \times 10^{-3}\ T + 1.89 \times 10^{-4}\ T^3\ cal\ K^{-1}\ mol^{-1}$. The S°(298.15 K) value calculated from the polynomials agrees to within 0.002 cal K^{-1} mol^{-1} with that given by Boerio and Westrum (1) and adopted by Gurvich et al. (3).

Boerio and Westrum (1) used adiabatic-shield calorimetry to measure the low temperature heat capacity, 83 data points in the range 6.28 to 346.42 K. Two other studies have also been made: Kreplovich and Paukov (5-300 K (4, 5)) and Roberts (1-20 K (6)). In the temperature region below 20 K, both these studies deviate from the adopted values similarly, from ~44% low at 5 K to ~15% low at 20 K. Since the sample used by Kreplovich and Paukov (4, 5) was shown to contain a substantial oxygen impurity, of the order of 6 ± 3 mole percent (1), the sample used by Roberts (6) probably had similar impurities. Roberts reported a purity of 98.25% but only metallic impurities were analyzed.

Stephens and Roth (2) measured enthalpy (350-1191 K) by drop calorimetry and heat capacity (298-785 K) by differential scanning calorimetry. We fit the 14 enthalpy points at 400-812 K with a polynomial, using the adiabatic (1) and DSC (2) data as a guide to the shape of the heat capacity curve. We adopt this fit only above 350 K, although the derived $C_p°$ values agree closely (±0.3%) with the adiabatic data (1) at 250 to 320 K. Between 320 and 400 K the adopted $C_p°$ values are a compromise between those of Boerio and Westrum and those of Stephens and Roth. This compromise yields an upward inflection point in $C_p°$ versus T near 330 K. The largest deviation of Boerio and Westrum (1) above 320 K is -0.7% at 343.42 K. The DSC data (2) deviate by -0.8 to +2.0% except for +3.8% at 785 K. The enthalpy data (2) deviate by -1.6 to +1.8% (400-812 K) with larger deviations at 350 and 550 K.

Phase Data

According to Pearson (7), α-strontium has the face-centered-cubic structure, isotypic with Cu, designated as CF4. In the alkaline earth metal series, only α-calcium has the same structure.

Transition Data

See the β-crystal table for details.

Sublimation Data

The enthalpy of sublimation of α-strontium is the enthalpy of formation of the gas. The experimental studies are discussed in the ideal gas table.

PREVIOUS: December 1970 CURRENT: September 1983

STRONTIUM (β-Sr) CRYSTAL A_r = 87.62

Pearson Notation: cI2

$S°(298.15\ K) = [57.1748]\ J\ K^{-1}\ mol^{-1}$

$T_{trs}(\alpha \rightarrow \beta) = 820 \pm 8\ K$

$T_{fus}(\beta \rightarrow \ell) = 1050 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [1.21126]\ kJ\ mol^{-1}$

$\Delta_{trs} H°(820\ K) = 0.8368 \pm 0.17\ kJ\ mol^{-1}$

$\Delta_{fus} H°(1050\ K) = 7.4308 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°$(Sr, cr, β, 298.15 K) is calculated from $\Delta_f H°$(Sr, α, cr, 298.15 K) by adding the enthalpy of transition, $\Delta_{trs} H°$, and the difference in enthalpy, H°(820 K)-H°(298.15 K), between α-Sr and β-Sr.

Heat Capacity and Entropy

The drop-calorimetry data of Stephens and Roth (1) contain 9 points (819.6-1048.8 K) that appear to be in the region of stability of β-strontium. Their values of [H°(T)-H°(298.15 K)]/(T-298.15) show systematic curvature suggestive of the effects of incomplete transition or premelting near the extreme temperatures. Constant $C_p°$ values ranging from ~6.3 to 9.3 cal K^{-1} mol^{-1} can be derived by various selections and weightings of the points. We arbitrarily select a $C_p°$ near 7.3 cal K^{-1} mol^{-1} with a linear temperature dependence that maintains the proper stability relationships when extrapolated below T_{trs} and above T_{fus}. This curve reproduces the enthalpy data within ±1.2% (819.6-990.5 K) and corresponds to premelting effects of ~140 to 450 cal/mol in the region from 1029 to 1049 K. S°(298.15 K) is calculated from that of α-strontium using entropy increments analogous to the enthalpy increments used to calculate $\Delta_f H°$(298.15 K).

Phase Data

According to Pearson (2), β-strontium has the body-centered-cubic structure, isotypic with W, designated as CI_2. In the alkaline earth metal series, β-calcium, β-beryllium, and barium have the same structure. Note that we now use the name beta (3) for the phase of Sr stable near T_{fus}, unlike Pearson who retains the historical name gamma. The change arose when Peterson and Colburn (3) found that an intermediate hexagonal-close-packed phase does not occur in Sr containing a smaller amount of H_2 impurity.

Transition Data

We select T_{trs} = 820 ± 8 K based on enthalpy data of Stephens and Roth (1) and DTA data of Peterson and Colburn (3). DTA gave ~813 K on cooling and 828 K (after correction for H impurity) on heating. We adopt an enthalpy of transition of 200 ± 40 cal/mol derived from our fits of the enthalpy data (1) for β and α phases; Stephens and Roth selected the same value. Almost 170 out of the 200 cal/mol appeared between 812 and 819.6 K. Another 30 cal/mol appeared between 819.6 and 824.9 K, while possibly 40 cal/mol appeared between 824.9 and 835.6 K. The latter enthalpy increments are uncertain because of almost equal-sized scatter in the data and because of uncertainty in $C_p°(\beta)$. Our adopted value of T_{trs} = 820 K is in the middle of the DTA hystersis range. The temperature range up to T_{trs} includes most of the transition enthalpy seen in the sample of Stephens and Roth. Their sample was identical with that used by Boerio and Westrum (4) to measure the low temperature $C_p°$ and S° of α phase.

Peterson and Colburn (3) found that T_{trs} increased rapidly with increasing hydrogen content. They also observed the intermediate hexagonal-close-packed phase at hydrogen contents of >3 mole % but not at 0.4 mole %, suggesting that this phase does not occur in pure strontium. The enthalpy and heat capacity data (1) are consistent with this interpretation.

Sublimation Data

The enthaply of sublimation of β-strontium is calculated as the difference in the enthlapies of formation of the gas and β-strontium. The experimental studies are discussed in the Sr(g) table.

PREVIOUS: CURRENT: September 1983

$S°(298.15\ K) = [50.901]\ J\ K^{-1}\ mol^{-1}$

$T_{fus}(\beta+\ell) = 1050 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [0.911]\ kJ\ mol^{-1}$

$\Delta_{fus} H°(1050\ K) = 7.4308 \pm 0.8\ kJ\ mol^{-1}$

Enthalpy of Formation

$\Delta_f H°(Sr, \ell, 298.15\ K)$ is calculated from $\Delta_f H°(Sr, cr, \beta, 298.15\ K)$ by adding the enthalpy of fusion, $\Delta_{fus} H°$, and the difference in enthalpy, $H°(1050\ K)-H°(298.15\ K)$, between β-Sr and the liquid.

Heat Capacity and Entropy

$C°_p$ *is the constant value derived from three enthalpy points (1059-1191 K) measured by Stephens and Roth (1). Their points deviate from the adopted enthalpies by -0.8 to +0.5%. We assume a glass transition with zero enthalpy at 650 K; below 650 K we assume that* $C°_p$ *(glass) is equal to the* $C°_p$ *(alpha) curve derived from the enthalpy data for alpha strontium (see that table). These or similar assumptions are necessary to ensure that S°(298.15 K) of the supercooled liquid is larger than that of alpha α-strontium. S°(298.15 K) is calculated from that of β-strontium using entropy increments analogous to the enthalpy increments used to calculate* $\Delta_f H°(298.15\ K)$.

Fusion Data

T_{fus} = 1050±10 K is the value selected by Stephens and Roth (1) based on their enthalpy study. Previous studies by thermal analysis (2-3) gave 1042±2 K (IPTS-68) for high-purity strontium. The reason for the difference is not clear; although it probably arises from differences in sample purity or measurement method. The observed enthalpies (1) showed that melting of the sample was complete at 1059.1 K but only ~20 to 30% complete at 1048.8 K. This suggests either that the sample needed a much longer equilibration time at 1048.8 K or that it actually melted at least 7 degrees higher than 1042 K. The enthalpy at 1035.1 K showed a small premelting effect. A melting point of 1048 K (IPTS-68) was found by Kanda and coworkers (4-6) for three samples that, based on their transition behavior, probably contained over 3 mole % of hydrogen. Although hydrogen increases both T_{fus} and T_{trs}, the changes are greatest in the transition region (2). The sample in the enthalpy study had normal transition behavior without the changes typical of hydrogen impurity. This sample was identical to that used in measurement of $C°_p$ and S° at low temperature; analytical data (7) showed it to be of high purity. We choose to base all properties, including melting point, on the data for this same sample

The enthalpy of fusion is derived from our fits of the enthalpy data (1) in the liquid and beta regions. Stephens and Roth (1) selected the value 1871±55 cal/mol based on a somewhat different fit in the beta region.

Vaporization Data

T_{vap} is calculated as the temperature for which $\Delta_{vap} G° = 0$ for the liquid vaporizing to the ideal monatomic gas. T_{vap} corresponds to a fugacity of one bar. The enthalpy of vaporization is calculated from the enthalpy of formation of the liquid and the gas at T_{vap}. Vaporization studies are discussed in the ideal gas table (8).

Enthalpy of Formation

The enthalpy of formation is the enthalpy of sublimation, 164.0±1.7 kJ mol^{-1}. The adopted value is derived mainly from the boiling point study of Bohdansky and Schins (1). It is confirmed by the early data of Hartmann and Schneider (2) and by the Knudsen effusion - mass - spectrometric study of Boerboom et al. (4). Data of Ruff and Hartmann (3) are readily dismissed due to the large entropy discrepancy.

A complete reanalysis of all the alkaline earth metals is in progress.

Source	Method	T/K	$\Delta_f H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	δS cal K mol
(1) Bohdansky (1967)	Boiling Point	1218-1982	40.1±0.4	39.16±0.46	0.6±0.3
(2) Hartmann (1929)	Boiling Point	1200-1380	40.0±0.6	39.46±0.14	0.4±0.4
(3) Ruff (1924)	Boiling Point	1218-1412	77 ±4	38.0 ±5	29 ±3
(4) Boerboom (1964)	Effusion-Mass Spec.	772-923	36.4	39.04±0.39	-3.1
(5) Priselkov (1954)	Effusion	673-873	35.7±0.5	38.65±0.57	-3.8±0.6

[a]Temperatures are adjusted to IPTS-68 by assuming published values to be IPTS-48.

Heat Capacity and Entropy

Observed energy levels and quantum weights are from Moore (6) as modified by Garton et al. (7, 8). Energies of unobserved but predicted terms (6) are estimated by comparison of Ca I, Sr I, Ba I and their isolectronic ions. The most important energies are for terms of the 4d5s' configuration which are erstimated at 25000 ± 10000 cm^{-1}. We adopt an energy-level cutoff which is about kTmax (Tmax - 6000 K) below each series limit. For Sr I this corresponds to omitting levels above 8s, 7p, 6d and 5f. Levels above 30000 cm^{-1} are averaged. The adopted functions are essentially identical with earlier tables up to 3000 K; however, the entropies at 6000 K differ as follows: Hilsenrath et al. (9), 57.49; Gurvich et al. (10), 58.80 cal K^{-1} mol^{-1}. These differences arise from different methods of cutoff and different degrees of accounting for the unobserved terms.

Enthalpy of Formation

$\Delta_f H°(Sr^+, g, 0\ K)$ is calculated from $\Delta_f H°(Sr, g, 0\ K)$ (1) using the spectroscopic value of IP(Sr) = 45932.0 ± 0.2 cm^{-1} (549.469 ± 0.002 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Sr^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Sr, g, 0\ K)$ by using IP(Sr) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Sr(g), Sr^+(g), and e^-(g). $\Delta_f H°(Sr + Sr^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the levels listed above; the next excited state is approximately 53286 cm^{-1} above the ground state. Since inclusion of these higher excited states have little effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first four excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

$S°(298.15\ K) = 41.47 \pm 0.21\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3258 \pm 10\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 36.57 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity values for T ≤ 10 K are chosen to be the same as those adopted by Hultgren et al. (1). A graphical integration of these Cp° data yields S°(10 K) = 0.025 cal $K^{-1}mol^{-1}$. The adopted Cp° values for the range 10 ≤ T ≤ T_{fus} are based on the following experimental data.

Source	T/K	Method
(2)	53-295	Cp°
(3)	10-273	Cp°
(4)	12-550	Cp°
(5)	300-1554	drop, enthalpy
(6)	533-1383	drop, enthalpy
(7)	1900-3200	Cp°, pulse heating

The data of Cezairliyan (7), reported as smoothed Cp° values and represented by a third-order polynomial, yields Cp° values from 3200 K to T_{fus} by extrapolation. These smooth Cp° values, as reported by Cezirliyan (7), are adopted for the range 1900-3200 K. Using a polynomial fit for each enthalpy data set (5, 6), Cp° values are obtained which define the region 298-1500 K. A polynomial, constrained at 10 K, is used to produce smoothed Cp° values in the range 10-298 K based on the three low temperature studies (3, 4, 5).

For T < 100 K, the tabulated values do not agree well with the experimental data. In this region the deviations from the tabulated values are ±5% for Clusius and Losa (3), -0.3 to +1.9% for Kelley (2), and -1.7 to 2.8% for Sterrett and Wallace (4). The deviations are due in part to experimental scatter (3) and a poor match of experimental data at 10 K.

Many other experimental studies have been referenced by Gmelin (8) and Hultgren et al. (1). In addition, Cezairliyan (7) has compared graphically many of the investigations. The Cp° data and enthalpy data are all in generally good agreement. The importance of the recent Cezairliyan study (7) is that it gives added evidence to the deviation from a linear Cp-T relationship above 1000 K.

Fusion Data

The melting point of Ta is chosen as 3258 ± 10 K based on the subsecond pulse heating technique of Cezairliyan (7). This choice is made so as to have a T_{fus} consistent with Cp° data at temperatures near T_{fus} (see heat capacity discussion). Other T_{fus} values covering the range 3053-3273 K are referenced by Charlesworth (9); while additional references are found in Gmelin (8). Hultgren et al. (1) recommends a T_{fus} value of 3287 K.

The enthalpy of fusion, $\Delta_{fus}H°$, for Ta has been measured by Lebedev, Savvatimskii, and Smirnov (10). They reported a $\Delta_{fus}H°$ value of 8.74 ± 0.5 kcal mol^{-1} based on measurements made during electrical explosion in thin wires. We adopt this value for $\Delta_{fus}H°$. Based on $\Delta_{fus}H°$ = 8.74 kcal mol^{-1} and T_{fus} = 3258 K, the entropy of melting, $\Delta_{fus}S°$, is calculated to be 2.68 cal $K^{-1}mol^{-1}$. This compares with $\Delta_{fus}S°$ = 2.33 cal K^{-1} mol^{-1} for Nb, as reported in these tables.

TANTALUM (Ta) LIQUID A_r = 180.9479

$S°(298.15\ K) = [50.366]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3258 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [30.795]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 36.57 \pm 4.2\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Ta(ℓ) at 298.15 K is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(3258 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity for Ta(ℓ) is estimated as 10.0 cal K^{-1} mol^{-1} by analogy with other monatomic metals. The same value was adopted by Hultgren et al. (1) and Stull and Sinke (2). A glass transition is assumed at 2150 K. Below this temperature, the heat capacity values used are those of Ta(cr). The entropy at 298.15 K is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

See the crystal table for details.

Vaporization Data

T_{vap} is the temperature at which the Gibbs energy change for the reaction Ta(ℓ) → Ta(g) is zero. The difference between $\Delta_f H°$(Ta, g) and $\Delta_f H°$(Ta, ℓ) at T_{vap} is $\Delta_{vap}H°$. The uncertainty in the boiling point is probably of the order of ±200 K.

Enthalpy of Formation

The enthalpy of sublimation of tantalum has been derived from 2nd and 3rd law analysis of the vapor pressure data of several investigators. These four studies are based on the Langmuir method.

Source	T/K	Data Points	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}
(1)	2628-2952	7	190.0±3.0	186.9	-1.1±1.1
(2)	2004-3269	16*	183.0	186.9	1.5

(4)	2904-3155	8**	233.1	190.3	-14.2

*Only smooth data was reported; however, 16 refers to the number of experimental determinations.
**Only smooth data reported.

Babeliowsky (5) reported an enthalpy of sublimation value of 168.4 ± 4.0 kcal mol^{-1}. This value is based on mass spectrometric vaporization studies and is calculated by the 2nd law method. Sasaki et al. (6), also using a mass spectrometer, reported an enthalpy of sublimation value of 185.4 ± 0.3 kcal mol^{-1} as an average value in the range 2550-2770 K. The value chosen for the enthalpy of sublimation which, in this case, is the enthalpy of formation of Ta(g) is 186.9 ± 0.5 kcal mol^{-1}, based on the work of Edwards et al. (1) and Langmuir and Malter (2).

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from Moore (7). Although not all levels are listed, all levels given by Moore are used in the calculation. There are predicted electronic levels which have not been observed (7). These levels are assumed to lie above 20000 cm^{-1} and thus will not significantly affect the entropy at temperatures below 3000 K. The heat capacity and entropy values are very similar to those adopted by Hultgren et al. (8), being identical at 298.15 K and differing by 0.154 cal K^{-1} mol^{-1} in Cp° at 6000 K.

Enthalpy of Formation

$\Delta_f H°(Ta^+, g, 0\ K)$ is calculated from $\Delta_f H°(Ta, g, 0\ K)$ (1) using the spectroscopic value of IP(Ta) = 63600 ± 100 cm^{-1} (760.825 ± 1.20 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Ta^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Ta, g, 0\ K)$ by using IP(Ta) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Ta(g), $Ta^+(g)$, and $e^-(g)$. $\Delta_r H°(Ta \rightarrow Ta^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2), is incomplete because many theoretically predicted levels have not been observed. Although we have only a few of the atomic energy levels for $Ta^+(g)$, all levels listed by Moore (2), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $Ta^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=6), and the cut-off procedure up to 6000 K; the Gibbs energy function showing no significant variations at this temperature. The reported uncertainty is S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>6), and use of different fill and cut-off procedures (6)u

PREVIOUS: CURRENT: March 1984 (1 bar)

TANTALUM, ION (Ta^-) IDEAL GAS M_r = 180.94855

EA(Ta, g) = 0.322 ± 0.012 eV

$S°(298.15\ K) = 174.560 \pm 0.002\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 750.403 \pm 1.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [744.941]\ kJ\ mol^{-1}$

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^5D_0$	0.0	1
$^5D_1$	1070	3
$^5D_2$	2240	5

Enthalpy of Formation

$\Delta_f H°(Ta^-, g, 0\ K)$ is calculated from $\Delta_f H°(Ta, g, 0\ K)$ (1) using the adopted electron affinity of EA(Ta) = 0.322 ± 0.012 eV (31.068 ± 1.158 $kJ\ mol^{-1}$). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Ta^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Ta^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Ta, g, 0\ K)$ by using EA(Ta) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Ta^-(g)$, Ta(g), and $e^-(g)$. $\Delta_r H°(Ta^- + Ta + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Ta^-(g)$ is given by Hotop and Lineberger (2, 4), Rosenstock et al (5), and Massey (6). The fine structure separation has been calculated by an isoelectronic extrapolation of ratios of fine structure separations (3) and is that recommended by Hotop and Lineberger (2).

$\Delta_{trs} H° = 0.997 \pm 0.03\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition

Heat Capacity and Entropy

The adopted thermal functions for α-Ti(cr) are derived from the studies of Collings and Ho (1), Clusius and Franzosini (2), Stalinski and Bieganski (3), Scott (4), Backhurst (5) and Cezairliyan (6). The mathematical and graphical treatment of these four studies yields a continuous and smooth heat capacity curve.

There are ten studies (1, 7 - 15) on the heat capacity of titanium in the range 1-5 K. Wolcott (8) and Aven et al. (7) reported the experimental data. In the other studies, an equation (with two constants) was given to describe the entire set of experimental data. The constants given by Collings and Ho (1) agree with the experimental data of Wolcott (8) and of Aven et al. (7). The maximum difference in the calculated values for S°(5 K) is 0.00071 cal K^{-1} mol^{-1}, with the adopted value being S°(5 K) = 0.0043 cal K^{-1} mol^{-1}. Similarly for Cp°(5 K) the maximum difference is 0.00211 cal K^{-1} mol^{-1}, with the adopted value being Cp° (5 K) = 0.0049 cal K^{-1} mol^{-1}.

In the region above 5 K and below 360 K, there are seven heat capacity studies (2, 3, 8, 9 - 18). The adopted values were based on the work of Clusius and Franzosini (2) and Stalinski and Bieganski (3). The maximum deviation of all studies from the adopted is 2.5% over this temperature range.

Above 300 K, there are eleven heat capacity studies (4, 5, 6, 18 - 25) and seven enthalpy studies (26 - 32). The heat capacity studies all have a similar temperature dependence in comparison with the adopted values. However, the studies of Holland (19), Affortit (23), Arutyunov (24), and Rumyantsev (25) lie roughly 9-33% higher than the adopted values. There is much scatter in all studies within 50 K of the α-β transition temperature. The adopted values were based on Scott (4), Backhurst (5), and Cezairliyan (6). The enthalpy studies show a large scatter within each study as well as a general lack of agreement between the studies.

Transition Data

Refer to the β-crystal table for details.

Sublimation Data

There are no sublimation studies involving α-Ti(cr). The enthalpy of sublimation is calculated as the difference between the enthalpy of formation of the monatomic gas and the enthalpy of formation of α-Ti(cr).

PREVIOUS: September 1966 CURRENT: June 1979

TITANIUM, BETA (β-Ti) CRYSTAL A_r = 47.88

$S°(298.15\ K)$ = [38.122] J K^{-1} mol^{-1}
T_{trs} = 1166 ± 10 K (α - β)
T_{fus} = 1939 ± 10 K (β - ℓ)

$\Delta_f H°(298.15\ K)$ = [6.860] kJ mol^{-1}
$\Delta_{trs} H°$ = 4.172 ± 0.13 kJ mol^{-1}
$\Delta_{fus} H°$ = 14.146 ± 5.0 kJ mol^{-1}

Enthalpy of Formation

The enthalpy of formation is calculated from that of the α-crystal by addition of $\Delta_{trs}H°$ and the difference in enthalpy, H°(1166 K) - H°(298.15 K), between the α-crystal and the β-crystal.

Heat Capacity and Entropy

For the β-crystal there are ten heat capacity studies and six enthalpy studies. The discussion on heat capacity and enthalpy on the α-Ti(cr) table also applies to the β-Ti(cr).

The entropy at 298.15 K is calculated in a manner similar to that for the enthalpy of formation.

Phase Data

Titanium, at ambient pressures, exists in two crystal modifications. The low temperature form, α-Ti, is hexagonal close packed, an hcp (A3) structure isotypic with Mg. The high temperature form, β-Ti, is body centered cubic, a bcc (A2) structure isotypic with W.

Transition Data

The following table indicates the values of transition temperatures and enthalpies of transition reported by various investigators. The value of T_{trs} adoped is 1166±10 K, and the value of $\Delta_{trs}H°$ is selected as 0.997±0.03 kcal mol^{-1}, based on the work of Cezairliyan and Miller (1).

Source	T_{trs}/K	$\Delta_{trs}H°$, kcal mol^{-1}	Purity, %	Method

Fusion Data

Refer to the liquid table for details.

Sublimation Data

There are three sublimation studies involving β-Ti(cr). They are summarized on the ideal gas table. The enthalpy of sublimation for β-Ti(cr) is calculated as the difference in the enthalpies of formation at 298.15 K of Ti(g) and β-Ti(cr).

PREVIOUS: September 1966 CURRENT: June 1979

$S°(298.15\ K) = [39.181]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 1936 \pm 10\ K$

$\Delta_f H°(298.15\ K) = [13.652]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 14.146 \pm 5.0\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the β-crystal by addition of $\Delta_{fus}H°$ and the difference in enthalpy, H°(1936 K) - H°(298.15 K), between the β-crystal and the liquid.

Heat Capacity and Entropy

There are two enthalpy studies (1, 2) covering the liquid region of titanium. The work of Treverton and Margrave (1) was adopted. A glass transition is assumed at 1300 K below which extrapolated β-Ti heat capacity values are used. The entropy is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The investigators reporting melting temperatures and heats of melting are listed below. The value of T_{fus} adopted is 1939±10 K, and the value of $\Delta_{fus}H°$ is selected as 3.381±0.03 kcal mol^{-1}, based on the work of Berezin et al. [164].

Source	T_{fus}/K	$\Delta_{fus}H°$ kcal mol^{-1}

Oriani and Jones (9)	1945	
Deardorff and Hayes (10)	1941	
Westrum and Feick (11)	1933	
Elyutin et al. (12)	1941	4.1±0.1
Treverton and Margrave (1)	1943	3.161±0.12
Berezin et al. (13)	1939	3.381±0.115

Vaporization Data

The two vaporization studies are summarized on the ideal gas table. The boiling point is calculated as that temperature for which ΔG° = 0 for Ti(ℓ) = Ti(g). $\Delta_{vap}H°$ is the corresponding enthalpy change. T_{vap} is the temperature at which fugacity is one bar. The normal boiling point (p=1 bar) would be a slightly lower temperature.

Enthalpy of Formation

The value adopted for the enthalpy of formation of Ti(g) is that recommended by CODATA (1). It is obtained from a 2nd and 3rd law evaluation of the vapor pressure data of Wu and Wahlbeck (2), Berstein and Kaufman (3), Koch et al. (4), Strassmair and Stark (5), and Edwards, Johnston, and Ditmars (6).

Source	Reaction	T/K	Data Points	$\Delta_r H°(298.15K)$, kcal mol^{-1} 2nd Law	3rd Law	Drift cal K^{-1} mol^{-1}	$\Delta_f H°(298.15K)$ kcal mol^{-1}

*Two points deleted due to a statistical test Reaction: a) Ti(β) = Ti(g) b) Ti(ℓ) = Ti(g)

Heat Capacity and Entropy

The electronic energy levels are given in the recent compilation by Corliss and Sugar (7). Although we have listed only the ground state, first two excited states, the highest observed excited state, and the ionization potential for Ti(g), all levels listed by Corliss and Sugar (7), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. In our calculations, the missing levels for n=4, n=5, and n=6 have been arbitrarily added near the ionization limit. Our calculations indicate that for Ti(g) the thermochemical functions are independent of the estimated missing levels (for n=4,5,6) and the cut-off procedure up to 3000 K. The Gibbs energy function is essentially unaffected (<0.002 cal K^{-1} mol^{-1}) at 6000 K. The reported uncertainty in $S°(298.15K)$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>6), more precise estimation of missing states (all n), and utilization of proper fill and cut-off procedures (8). In fact, the inclusion of some higher states (n=4,5,6) and consideration of various cut-off procedures leads to calculational differences in the Gibbs energy function of rougly 0.1 cal K^{-1} mol^{-1}) or greater at temperatures near 10000 K.

Enthalpy of Formation

$\Delta_f H°(Ti^+, g, 0\ K)$ is calaculated from $\Delta_f H°(Ti, g, 0\ K)$ (1) using the spectroscopic value of IP(Ti) = 55010 ± 100 cm^{-1} (658.07 ± 0.4 kJ mol^{-1}) from Corliss & Sugar (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levon amd Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Ti^+, g, 298.15K)$ is calculated from $\Delta_f H°(Ti, g, 0\ K)$ by using IP(Ti) with JANAF (1) enthalpies, H°(0 K) - H°(298.15K), for Ti(g), $Ti^+(g)$, and $e^-(g)$. $\Delta_f H°(Ti \rightarrow Ti^+ + e^-, 298.15K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in this ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The electronic energy levels are given in the recent compilation by Corliss and Sugar (2). Although we have listed only the ground state, the first three excited states, the highest observed excited state, and the ionization potential for $Ti^+(g)$, all levels listed by Corliss and Sugar (2), as well as *estimated levels, are used in the calculation.* The observed levels are too numerous to list completely. In our calculations the missing levels for n=4,5 have been arbitrarily added near the ionization limit. The calculations indicate that for $Ti^+(g)$, the thermochemical functions are independent of the estimated missing levels for n=4,5,the cut-off procedure, and the inclusion of n=6 levels up to 6000 K. The Gibbs energy function is essentially unaffected (by less than 0.2%) up to 20000 K. The reported uncertainty in S°(298.15K) is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>6), and use of proper fill and cut-off procedures (6).

PREVIOUS: June 1979 (1 atm) CURRENT: March 1984 (1 bar)

EA(Ti, g) = 0.079 ± 0.014 eV

$S°(298.15\ K) = 183.715 \pm 0.001\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 463.3 \pm 4\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [459.833]\ kJ\ mol^{-1}$

Electonic Levels and Quantum Weights

State	ϵ_i, cm^{-1}	g_i
$^4F_{3/2}$	0.0	4
$^4F_{5/2}$	72	6
$^4F_{7/2}$	171	8
$^4F_{9/2}$	295	10

Enthalpy of Formation

$\Delta_f H°(Ti^-, g, 0\ K)$ is calculated from $\Delta_f H°(Ti, g, 0\ K)$ (1) using the adopted electron affinity of EA(Ti) = 0.079 ± 0.014 eV (7.622 ± 1.351 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Ti^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Ti^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Ti, g, 0\ K)$ by using EA(Ti) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Ti^-(g)$, Ti(g), and $e^-(g)$. $\Delta_r H°(Ti^- \rightarrow Ti + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Ti^-(g)$ is given by Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey(6). The fine structure has been calculated via an isoelectronic extrapolation from a logarithmic plot (3) and is that recommended by Hotop and Lineberger(2).

$S°(298.15\ K) = 28.936 \pm 0.42\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2190 \pm 20\ K$

$\Delta_f H° = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 22.84 \pm 6.28\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity values for temperatures below 10 K are those chosen by Hultgren (1). A graphical integration yeilds S°(10 K) = 0.0253 cal K^{-1} mol^{-1} and H°(10 K) - H°(0 K) = 0.147 cal mol^{-1}. *The adopted heat capacity values for 10 ≤ T ≤ 320 K are* obtained graphically, based on the following three works.

Source	Year	T/K	Purity of Vanadium
(2)	1936	54-297	reported ≥ 99.5%
(3)	1960	10-274	99.5%; remainder oxygen
(4)	1961	25-340	99.8%; metallic impurities <0.08%

The low temperature (T < 50 K) results of Clusius et al. (3) do not join smoothly with the values adopted for T < 10 K. This mismatch is in part due to the oxygen *impurity in the vanadium sample used* by Clusius et al. (3). In order to effect a smooth joining of the Cpd values, a graphical representation of Cp(lattice)/T^3 versus T for the Hultgren data (1) and the Clusius et al. data (3) was used to derive adjusted Cp° values. The three data sets (2, 3, 4) are in reasonably good agreement; *two sets* (2, 4) lie predominantly above the adopted values while the remaining set (3) lies below. Above 100 K, the three data sets differ from the adopted Cp° values by roughly 1%, with the difference decreasing as T increases.

For the region 320≤ T ≤ 2190, there are four works upon which the adopted Cp° values are based.

Source	Year	Method	T/K	Purity of Vandadium
(5)	1965	Cp°	320-1800	99.74%
(6)	1934	drop	565-1928	reported as "purest"
(7)	1962	drop	488-1486	0.1%C, 0.07, 0.03%N
(8)	1971	levitation	1989-2284	0.06% total impurities

The heat capacity values reported by Kohlhaas et al. (5) are 1-2% lower than the adopted values below 950 K; 0.3% higher in the region 950-1300 K; and 7% lower above 1600 K. The results of Golutvin and Kozlowskaya (7) show considerable scatter and lie roughly 2-10% above the tabulated enthalpy values. The enthalpy data of Jaeger and Veenstra (6) do not join smoothly with that of *Berezin et al. (8). In the region* 1500-2000 K the adopted enthalpy values are a compromise between the latter two sets of data. Below roughly 1100 K the adopted enthalpy and that reported by Jaeger and Veenstra (6) differ at most by ± 15 cal mol^{-1}. From 1300-1800 K the difference increases from *70 cal* mol^{-1} *to 308 cal* mol^{-1} *or from 1.0% to 2.6%. The enthalpy* at 2190 K (T_{fus}) is very close to that which is obtained from a linear fit of the Berezin et al. data (8). Whereas the two sets of data (6, 8) separately indicate a Cp° value near T_{fus} to be at least 11 cal K^{-1} mol^{-1}, the compromise yields 10.5 cal K^{-1} mol^{-1}.

Fusion Data

See the liquid for details.

Transition Data

The literature indicates differences in opinion as to the possibility of a transition in the region 175-325 K and near 1825 K. *Although there are no detailed enthalpy measurements* in the 1825 K region, Barnes (9) used field-electron emission techniques to show that an allotropic trnsformation does not occur in vanadium in this region if the samples are of high purity. Earlier work concerning a possible transition in this regilon was *referenced by Barnes* (9).

Documentation exists in the literature as to the observation of anomalies in the temperature dependence of some physical properties of vanadium in the range 175-325 K. Although the anomaly was attributed by different workers to an antiferromagnetic transition, a small distortion of the body-centered cubic crystal structure, and impurities, Finkel' et al. (10) recently ascribed the anomaly to a second order phase transition at 230 K. Using low temperature x-ray diffraction techniques in the study of a *single crystal of vanadium*, Finkel' et al. (10) observed a decrease in crystal lattice symmetry form body-centered cubic (T > 230 K) to tetragonal (T < 230 K). Nevertheless, Crangle and Smith (11) measured the specific heat of polycrystalline vanadium and confirmed the results of Clusius et al. (3) that no *appreciable anomaly in Cp° exists in vanadium* between 175 and 265 K. We do not adopt a ΔCp or $\Delta_t H$ value in the two previously mentioned regions.

Sublimation Data

See the ideal gas table for details.

PREVIOUS: CURRENT: June 1973

$S°(298.15\ K) = [36.136] J\ K^{-1}\ mol^{-1}$

$T_{fus} = 2190 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [17.288] kJ\ mol^{-1}$

$\Delta_{fus} H° = 22.84 \pm 6.28\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of V(ℓ) at 298.15 K is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy H°(2190) - H°(298.15 K), between the crystal and liquid. Refer to V(g) table for an additional $\Delta_f H°(298.15\ K)$ value as derived from effusion-mass spectrometric work (10).

Heat Capacity and Entropy

Enthalpy data in the liquid phase have been reported by Treverton and Margrave (1) and Berezin et al. (2). Using levitation calorimetry, Treverton and Margrave (1) determined the enthalpy of V(ℓ) in the range 2205-2638 K. They reported a least squares analysis of the enthalpy data in the form H°(T) - H°(298.15 K) = 11.6527T - 5837.7 where T is in Kelvins and the enthalpy difference is in cal mol^{-1}. The standard deviation of the experimental points from the calculated values was ±167 cal mol^{-1}. Berezin et al. (2) also used a form of levitation calorimetry and measured enthalpies in the region 1990-2325 K. For the liquid region their data were represented by H°(T) - H°(298.15 K) = 11.043T - 3776, with a standard deviation of ±90 cal mol^{-1}. These two works agree remarkably well for the Cp° value of V(ℓ). In the measured enthalpy region, the Treverton and Margrave data (1) lie lower than the Berezin et al. data (2) by roughly 600-700 cal mol^{-1}. The two linear representations of the data intersect at 3380 K. We adopt the enthalpy values of Berezin et al. (2) since this work contains enthalpy data surrounding the melting point and a T_{fus} value which is our adopted value.

Fusion Data

The adopted value of the enthalpy of fusion, $\Delta_{fus}H° = 5.46 \pm 1.50$ kcal mol^{-1} is based on the work by Berezin et al. (2). The actual value is calculated by taking the difference in the adopted value of H°(2190) - H°(298.15 K) for V(ℓ) and V(cr). Refer to the heat capacity discussion in the tables for V(cr) and V(ℓ).

Preliminary results of experiments by Berezin et al. (2) indicated that T_{fus} for 99.96% pure vanadium was close to 2190 K. Representative values of T_{fus} reported in the literature are tabulated below.

Source	Purity of V	T_{fus}, K
(3)	0.33% O, 0.078% N	2161 ± 10
	0.15% of 7 other impurities	
(4)	99.8-99.9%	2192 ± 2
(5)	purity not given	2223
	purified by electron zone fusion	
(6)	99.8%	2173 ± 25
(7)	purity not given	2193

We adopt T_{fus} = 2190 ± 20 K principally since it is consistent with the work upon which $\Delta_{fus}H°$ is based. The adopted T_{fus} value is also suggested by Charlesworth (8) in his compilation of elemental melting points.

Vaporization Data

The vaporization of V(ℓ) was studied by Farber and Srivastava (10). Refer to V(g) table for details. Kant and Lin (9), using a combination of effusion and mass-spectrometric techniques, reported the ratio of observed ion intensities relating to V_2(g) and V(g) and corresponding to the vaporization of vanadium in the range 2060-2316 K. This ratio is of the order of 10^{-6} which suggests that at least in this region the contribution of V_2(g) in the vapor phase may be neglected. Linearly extrapolating these data to T_{vap}, the V_2 partial pressure is of the order of 10^5 smaller than the V partial pressure.

T_{vap} is calculated as the temperature at which the Gibbs energy change for the reaction V(ℓ) → V(g) is zero. The difference between $\Delta_f H°(V, g)$ and $\Delta_f H°(V, \ell)$ at T_{vap} is $\Delta_{vap}H°$. The uncertainty in T_{vap} is probably of the order of ±50 K.

Enthalpy of Formation

The vapor pressure over vanadium was measured by Edwards et al. (1) using the Knudsen method and by Farber and Srivastava (6) using effusion-mass spectrometric techniques. Our 2nd and 3rd law analysis is tabulated below, where reaction (A) refers to the sublimation V(cr) = V(g) and reaction (B), the vaporization V(ℓ) = V(g).

Source	Reaction	Data Points	T/K	$\Delta_r H°(298.15\ K)$, kcal mol^{-1} 2nd Law	3rd Law	drift cal K^{-1} mol^{-1}
1	A	12+	1666-1882	121.67±0.99	122.95	0.72±0.55
6	A	7	1900-2155	121.60±1.48	123.45	0.91±0.73
6	B	6	2198-2412	113.04±5.34	119.18	2.65±2.30

*A statistical test discounted the 1766 K data point.

We adopt $\Delta_f H°(298.15\ K) = 123.2$ kcal mol^{-1} for V(g). This value, which is identical to $\Delta_{sub} H°(298.15\ K)$, is a median of the two sublimation studies. Hultgren et al. (2) reported a 3rd law value of 123.089 ± 0.250 kcal mol^{-1} based on a Knudsen vapor pressure study in the range 1771-1880 K by Saxer (3). This result is consistent with our adopted value.

The results of Kant and Lin (5) indicated that the partial pressure of $V_2(g)$ is negligible in the temperature ranges studied above.

Heat Capacity and Entropy

The electronic energy levels and quantum weights are obtained from Moore (4). Only a few of the levels are listed above. All levels reported by Moore (4) are considered in the calculation. The heat capacity and entropy values are very similar to those adopted by Hultgren et al. (2), being identical at 298.15 K and differing by 0.045 cal K^{-1} mol^{-1} in Cp° at 3800 K. There are predicted levels which have not been observed and/or classified. It is not expected that S°(298.15 K) would be affected by the missing states, but that in the range 3000-6000 K, an error of 0.2-0.3 cal K^{-1} mol^{-1} might result.

$IP(V^+, g) = 118200 \pm 200\ cm^{-1}$

$S°(298.15\ K) = 183.38 \pm 0.8\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 1162.5 \pm 8\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [1171.947]\ kJ\ mol^{-1}$

Electronic Levels and Quantum Weights

State	ε_i cm^{-1}	g_i
$^5D_0$	0.00	1
$^5D_1$	36.05	3
$^5D_2$	106.83	5
$^5D_3$	208.89	7
$^5D_4$	339.21	9
$^5F_1$	2604.82	3

Enthalpy of Formation

$\Delta_f H°(V^+, g, 0\ K)$ is calculated from $\Delta_f H°(V, g, 0\ K)$ (1) using the spectroscopic value of IP(V) = 54360 ± 16 cm^{-1} (650.290 ± 0.19 kJ mol^{-1}) from Sugar and Corliss (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(V^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(V, g, 0\ K)$ by using IP(V) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for V(g), $V^+(g)$, and $e^-(g)$. $\Delta_f H°(V + V^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Sugar and Corliss (2), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first excited state, the highest observed excited state, and the ionization potential for $V^+(g)$, all levels listed by Sugar and Corliss (2), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $V^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=4, 5), the cut-off procedure, and the inclusion of n=5 levels up to 6000 K; the Gibbs energy function showing variations of 0.001 J $K^{-1}mol^{-1}$ at this temperature. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass, and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>5), and use of different fill and cut-off procedures (6).

VANADIUM, ION (V^-) IDEAL GAS M_r = 50.94205

EA(V, g) = 0.525 ± 0.012 eV

$S°(298.15\ K)$ = 183.436 ± 0.002 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 461.547 ± 2.5 kJ mol^{-1}

$\Delta_f H°(298.15\ K)$ = [458.588] kJ mol^{-1}

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^5D_0$	0.0	1
$^5D_1$	35	3
$^5D_2$	105	5
$^5D_3$	205	7
$^5D_4$	330	9

Enthalpy of Formation

$\Delta_f H°(V^-, g, 0\ K)$ is calculated from $\Delta_f H°(V, g\ 0\ K)$ (1) using the adopted electron affinity of EA(V) = 0.525 ± 0.012 eV (50.654 ± 1.158 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $V^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(V^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(V, g, 0\ K)$ by using EA(V) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $V^-(g)$, V(g), and $e^-(g)$. $\Delta_r H°(V^- \rightarrow V + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $V^-(g)$ is given by Hotop and Lineberger (2, 4), Rosenstock et al (5), and Massey(6). The fine structure separation has been calculated by an isoelectronic extrapolation of ratios of fine structure separations (3) and is that recommended by Hotop and Lineberger (2).

$S°(298.15\ K) = 32.660 \pm 0.10\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3680 \pm 20\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 35.40 \pm 10.5\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

There have been several investigations of the low temperature heat capacity of tungsten; Lange (1) covered the range 26-91 K. Horowitz and Daunt (2) reported values in the range 1-77 K, while Waite et al. (3) worked from 4-15° and DeSorbo (4) from 15-90 K. Zwikker and Schmidt (5) covered the range from 90 to 2521 K. Clusius et al. (6) made a thorough study of the heat capacity in the range 12-274 K, and their measurements were adopted leading to $S°(298.15\ K) = 7.806\ cal\ K^{-1}\ mol^{-1}$ based on $S°(12.5) = 0.0088\ cal\ K^{-1}\ mol^{-1}$. This value is in disagreement with the quoted value of $7.83\ cal\ K^{-1}\ mol^{-1}$ but agrees exactly with a separate integration by Kirillin et al. (7). In the intermediate temperature range the adiabatic heat capacity measurements of Bronson et al. (8) from 253 to 773 K joined well with the low temperature measurements and were adopted. The high temperature enthalpies have been measured by several investigators from which were selected the values of Jaeger and Rosenbohm (9) from 273-1800 K; Magnus and Holzmann (10) who covered the range 373 to 1173 K; Hoch and Johnston, (11) who made measurements between 1382 and 2900 K; Kirillin et al. (7) who have made several determinations over the range 600 to 3100 K, and have also analysed the above data and have presented smooth functions from 0 to 3500 K. The present table agreess with that of Kirillin et al. (7) up to 2700 K, above this temperature the values of Cp adopted follow those reported by Novikov et al. (12) measured by an electric modulation method, up to the melting point. These values rise rapidly above 2700 K and are not inconsistent with the individual measurements of Kirillin et al (7) at their highest temperatures.

Fusion Data

Langmuir (13) determined the melting point as 3540 K from intrinsic brilliance measurements; this was later corrected to 3655 ± 30 K by Jones et al. (14), and Pirani and Alterthum (15) from pyrometer measurements on a black body hole found 3660 ± 60 K. Using the same technique Zalabak (16) reports 3680 K on a low carbon specimen. He reports a decrease of the melting point with increasing carbon content. Rudy and Windisch (17) report a melting point of 3696 ± 20 K. The value adopted is 3680 K ± 20 K. The enthalpy of melting is obtained by assuming an entropy of melting of $2.3\ cal\ K^{-1}\ mol^{-1}$ obtained from a comparison of several high melting metals (Fe, Cu, Co, Mg, Al).

Sublimation Data

See ideal gas table for details.

PREVIOUS: December 1961 CURRENT: June 1966

$S°(298.15\ K) = [45.678]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 3680 \pm 20\ K$

$\Delta_f H°(298.15\ K) = [46.896]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 35.40 \pm 10.5\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation at 298.15 K was calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(3680 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity was estimated as 8.5 cal mol^{-1} K^{-1} by analogy with other monatomic metals. The entropy at 298.15 K was calculated in manner analogous to that used for the enthalpy of formation. At 2450 K a glass transition is assumed below which the heat capacity was that of the crystal.

Fusion Data

See the crystal table for details.

Vaporization Data

The boiling point and enthalpy of vaporization are calculated from the adopted functions and enthalpy of sublimation in order to maintain proper thermodynamic consistency.

Enthalpy of Formation

The enthalpy of formation is the enthalpy of sublimation at 298.15 K; this has been obtained by a 2nd and 3rd law analysis of the vapor pressure data of three investigators.

Source	T/K**	Data Points	$\Delta_{sub}H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law	Drift cal K^{-1} mol^{-1}
1	2511-3053	12*	200.9 ± 3.6	201.57 ± 1.6	0.1 ± 1.4
2	2383-3123	14	214.8 ± 1.4	202.17 ± 2.5	-4.7 ± 0.5
3	2574-3183	10	202.4 ± 2.7	203.35 ± 1.2	0.4 ± 1.0

* 1 point rejected due to failure of a statistical test.
** All temperatures are taken from Szwarc (3) who has corrected the earlier measurements.

The values are remarkably good since even at the highest temperature the pressures are less than 10^{-6} atm; all workers used the Langmuir technique. Since the data of Refs. 1 and 3 do not drift, it may be assumed that the accommodation coefficient is unity or close to unity. The drift in the second set cannot be eliminated by assuming a non-unity coefficient, nor does there appear to be a constant pressure error. Most probably the drift is due to slight errors in temperature, for example if the readings were 24 K high at the low end and 10 K low at the high end the drift would be eliminated; errors of this magnitude are quite possible. The value adopted for $\Delta_{sub}H°(298.15\ K)$ is 203.4 ± 1.5 kcal mol^{-1}.

Heat Capacity and Entropy

The electronic energy levels are taken from those listed by Moore (4). Levels above 25000 cm^{-1} were averaged.

Enthalpy of Formation

$\Delta_f H°(W^+, g, 0\ K)$ is calculated from $\Delta_f H°(W, g, 0\ K)$ (1) using the spectroscopic value of IP(W) = 64400 ± 100 cm^{-1} (770.40 ± 1.20 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(W^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(W, g, 0\ K)$ by using IP(W) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for W(g), $W^+(g)$, and $e^-(g)$. $\Delta_f H°(W + W^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2), is incomplete because many theoretically predicted levels have not been observed. Although we have listed only the ground, the first four excited states, the highest observed excited state, and the ionization potential for $W^+(g)$, all levels listed by Moore (6), as well as estimated levels, are used in the calculation. The observed levels are too numerous to list completely. The calculations indicate that for $W^+(g)$, the thermodynamic functions are independent of the estimated missing levels (for n=6) and the cut-off procedure; the Gibbs energy function showing variations of 0.8% at this temperature. The reported uncertainty is S°(298.15 K) is due to uncertainties in the relative ionic mass, the fundamental constants, and the low lying atomic energy levels. Extension of these calculations above 6000 K may require consideration of the higher excited states (n>6), and use of different fill and cut-off procedures (7).

$S°(298.15\ K) = 188.781\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 771.147 \pm 2.0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [766.174]\ kJ\ mol^{-1}$

Electonic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^6S_{5/2}$	0.0	6

Enthalpy of Formation

$\Delta_f H°(W^-, g, 0\ K)$ is calculated from $\Delta_f H°(W, g, 0\ K)$ (1) using the adopted electron affinity of EA(W) = 0.815 ± 0.008 eV (78.635 ± 0.772 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $W^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(W^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(W, g, 0\ K)$ by using EA(W) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $W^-(g)$, W(g), and $e^-(g)$. $\Delta_r H°(W^- \rightarrow W + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $W^-(g)$ is given by Hotop and Lineberger (2, 4) and Rosenstock et al. (5). *Lacking any experimental evidence as to the stability of any excited states, we assume that no stable excited states exist.*

Zero by definition.

Heat Capacity and Entropy

Information on the electronic energy levels and quantum weights is taken from Moore (1, 9). Many of the theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (2) has no effect on the thermodynamic properties to 6000 K. This is undoubtedly a result of the high energy of these levels; the first excited level is over 67000 cm^{-1} above the ground state. Therefore, we list the ground state only. Extension to higher temperatures may require consideration of excited states and utilization of different fill and cutoff procedures (2).

The thermodynamic functions at 298.15 K agree exactly with recent CODATA recommendations (3) except for two minor changes. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, entropy differences of the order of 0.001-0.004 J K^{-1} mol^{-1} for the rare gases arise due to the use of slightly different values for R and the relative atomic mass; this table uses R = 8.31441 J K^{-1} mol^{-1}. Within these same minor changes, the tables agree within the estimated uncertainty with those by Hultgren et al. (4), Hilsenrath et al. (5), Gurvich et al. (8), and Wagman et al. (12). The estimated uncertainty is due to uncertainties in the relative atomic mass and fundamental constants which are based on the 1981 scale (6) and the 1973 values (7), respectively.

Phase Data

The triple point, 161.388 K, and boiling point, 165.060 K, are secondary fixed points of IPTS-68 (10, 11). Hultgren et al. (4) had recommended a triple point of 161.36 K (0.8059 atm) and a boiling point of 165.060 K (1 atm). These values are provided for the convenience of the reader and have not been evaluated by the present authors. As a result of the low values, the reference state for xenon is chosen to be the ideal gas at all temperatures. This may differ from the choice of other authors.

$^2P_{1/2}$	10537.01	2

Enthalpy of Formation

The ionization limit of neutral xenon (97834.0±0.1 cm^{-1}) reported by Moore (1) is adopted as $\Delta_f H°(0\ K)$ for $Xe^+(g)$. The ionization limit is converted from cm^{-1} to $kJ\ mol^{-1}$ using the factor, 1 cm^{-1} = 0.01196266 $kJ\ mol^{-1}$, which is derived from the latest CODATA fundamental constants (2). The uncertainty in the ionization limit is estimated to be ±0.1 cm^{-1} which corresponds to an uncertainty of ±0.001 $kJ\ mol^{-1}$ in the heat of formation. Rosenstock et al. (9) and Levine and Lias (11) have summarized additional ionization potential and appearance potential data. Gurvich et al. (8) and Wagman et al. (10) adopted the same ionization potential, but the use of slightly different fundamental constants by Wagman et al. (10) results in a heat of formation difference of 0.011 $kJ\ mol^{-1}$.

$\Delta_f H°(Xe^+, g, 298.15\ K)$ is obtained from $\Delta_f H°(Xe, g, 0\ K)$ by using IP(Xe) with JANAF (3) enthalpies $H°(0\ K)-H°(298.15\ K)$ for $Xe^+(g)$, Xe(r), and $e^-(r)$. $\Delta_r H°(Xe \rightarrow Xe^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (9). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 $kJ\ mol^{-1}$ if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights of Moore (4) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (5) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the $^2P_{1/2}$ level; the next lowest level is over 90000 cm^{-1} above the ground state. Since inclusion of these upper levels has no effect on the thermodynamic functions (to 6000 K) we list only the ground state and the $^2P_{1/2}$ state, with the energy of the latter state taken from a more recent study by Moore (1). The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and use of different fill and cutoff procedures (5).

The thermodynamic functions reported here agree with those of Green et al. (6), Hilsenrath et al. (7), and Gurvich et al. (8) except for two minor changes. First, the entropy differs by 0.1094 $J\ K^{-1}\ mol^{-1}$ because this table uses a standard state pressure of 1 bar, whereas the cited references used a pressure of 1 atm. Second, smaller differences arise from the use of different values for the fundamental constants, the relative ionic mass, and the position of the $^2P_{1/2}$ electronic level.

PREVIOUS: December 1978 (1 atm) CURRENT: December 1978 (1 bar)

Pearson Notation: hP2

$S°(298.15\ K) = 41.717 \pm 0.17\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 692.73\ K$

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 7.322 \pm 0.105\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted heat capacity values are derived from the low temperature heat capacity studies of Martin (1) and Zabetakis (2) and four high temperature enthalpy studies (3, 4, 5, 6). *The heat capacity values at the temperature where these two different* types of study join are forced to be smooth and continuous.

The results of Martin (1) differ from the adopted values by less than 1% in the range 14-30 K. The results of Zabetakis (2) also agree within 0.4% in the region 23-195 K. In the region 200-260 K, the data of Zabetakis (2) indicated a slight depression of ~0.2 cal K^{-1} mol^{-1} at the mid-point of this region. Other low temperature studies did not support this result, so that the adopted heat capacity values are smoothed in this region to be in better agreement with the studies of Behrens and Drucker (7), Bronson and Wilson (8), and Eichenauer and Schulze (9). The enthalpy data of Jaeger and Poppema (6), Eastman et al. (4), Ruer and Kremers (5), and Schubel (3) all agree within 1% of the adopted enthalpy vlaues.

The thermodynamic functions are based on $S°(12) = 0.0230$ cal K^{-1} mol^{-1} and $H°(12\ K) - H°(0\ K) = 0.20$ cal mol^{-1}. These values are obtained by integration of smoothed low temperature data and are in agreement with the values used by Martin (1) and Zabetakis (2). Below 0.850 ± 0.01 K, zinc is a superconductive element; this behavior is summarized in a recent review by Roberts (10). The literature survey for Zn was done in part by Hultgren (11), his help is greatly appreciated.

Fusion Data

We adopt $\Delta_{fus} H° = 1.750 \pm 0.025$ kcal mol^{-1}. This value is derived primarily from the adiabatic calorimetric study of Chiotti et al. (12). Numerous other studies (over 20) reported values in the range 1.504-1.850 kcal mol^{-1} with a mean of 1.735 kcal mol^{-1}.

The adopted value for T_{fus} = 692.73 K is a primary reference point on the IPTS-68 (13).

Sublimation Data

The sublimation studies are summarized on the Zn(g) table.

PREVIOUS: CURRENT: December 1978

$S°(298.15\ K) = [50.792]\ J\ K^{-1}\ mol^{-1}$

$T_{fus} = 692.73\ K$

$\Delta_f H°(298.15\ K) = [6.519]\ kJ\ mol^{-1}$

$\Delta_{fus} H° = 7.322 \pm 0.105\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation of Zn(ℓ) at 298.15 K is calculated from that of the crystal by adding $\Delta_{fus}H°$ and the difference in enthalpy, H°(692.73 K) - H°(298.15 K), between the crystal and liquid.

Heat Capacity and Entropy

The adopted heat capacity for Zn(ℓ) is 7.5 cal K^{-1} mol^{-1}. It is taken as a constant for the real liquid region. There are five enthalpy and two heat capacity studies on liquid zinc. The enthalpy studies are summarized in the following table. The Cp°(ℓ) value given is that derived from the enthalpy data assuming a linear temperature dependence.

Source	Year	Reference Temperature	No. of Observations Liquid	No. of Observations Total	T/K	Cp° (ℓ) cal K^{-1} mol^{-1}
(1)	1919	293	28	47	469-992	8.14
(2)	1920	293	15	18	675-1140	7.24
(3)	1926	273	6	14	323-1123	8.20
(4)	1926	291	4	9	483-914	6.69
(5)	1960	471	2	13	481-723	7.0

Forster and Tschentke (6) reported heat capacity data graphically in the region 723-973 K. Their study showed a heat capacity of approximately 8.2 cal K^{-1} mol^{-1} at the melting point with a steadily decreasing trend to 7.0 cal K^{-1} mol^{-1} at 973 K. Cordoba (7) measured heat capacities in the crystal and liquid region, including 22 experimental points in the liquid region up to 798.2 K. This study resulted in a parabolic temperature dependence, with a minimum at 730 K of Cp° = 6.8 cal K^{-1} mol^{-1} and rapidly increasing values on either side of this minimum.

All these heat capacity and enthalpy studies do not conclusively define the temperature dependence of the heat capacity of liquid zinc. In addition, some of these heat capacity and enthalpy studies (3, 4, 7) do not show good agreement with the adopted values in the crystal region. However, the adopted constant value is consistent with the experimental data (within the uncertainty of the data) and with the vaporization data. The literature survey for Zn was done in part by Hultgren (8).

Fusion Data

Refer to the crystal table for details.

Vaporization Data

There are numerous studies on the vaporization of liquid zinc (2, 9-22). These studies, when depicted graphically in a log p vs 1/T plot, show remarkably good agreement in the region T_{fus} to 1666 K (approximately 0.2 to 23000 mmHg) with the exception of the studies by Ruff and Bergdahl (10) and Piacente et al. (22). A 2nd and 3rd law analysis of all zinc vaporization studies up to 400 mmHg is summarized in the following table.

Vaporization Studies

Source	Year	Number Observations	Method	T/K	Drift cal mol^{-1} K^{-1}	$\Delta_{vap}H°(298.15\ K)$, kcal mol^{-1} 2nd law	3rd law
(9)	1919	7	boiling point	926-1198	-1.3±1.0	31.91±1.02	30.58±0.40
(10)	1920	5	transport	761-995	-0.1±0.1	29.67±0.10	29.62±0.04
(11)	1925	30	boiling point	857-960	-0.4±0.1	29.94±0.07	29.61±0.04
(12)	1926	21	static	903-1259	-0.6±0.1	30.22±0.14	29.58±0.10
(14)	1934	1	transport	954			29.68
(15)	1934	6	static	955-1089	0.6±0.7	28.90±0.66	29.52±0.16
(16)	1955	eqn	torsion effusion	700-900	0.0	29.60	29.60
(17)	1957	3	transport	862-1020	-0.2±0.1	29.76±0.05	29.62±0.02
(18)	1959	3	transport	823-923	0.6±0.1	29.08±0.04	29.62±0.06
(22)	1973	10	transpiration	826-1041	-0.1±0.3	29.94±0.25	29.86±0.11

Not including the results of Ruff and Bergdahl (10) and Piacente et al. (22), the mean of the tabulated 3rd law values is $\Delta_{vap}H°(298.15\ K) = 29.59 \pm 0.1$ kcal mol^{-1}. This may be compared with our adopted value of 29.531 derived from $\Delta_{fus}H°$ and $\Delta_f H°$(Zn, g, 298.15 K) = 31.1±0.2 kcal mol^{-1}. This difference of 0.059 kcal mol^{-1} is within the uncertainty of the vapor pressure studies. Refer to the ideal gas table for more details.

The boiling point is calculated as that temperature for which ΔG° = 0 for Zn(ℓ) = Zn(g). T_{vap} is the temperature for which the fugacity is one bar.

Enthalpy of Formation

The adopted value for the enthalpy of formation is that recommended by CODATA (1). This value is based on the reanalysis of the vapor pressure data cited by Hultgren et al. (2), and Gurvich et al. (3). The studies by Mar and Searcy (512-666 K, 4) and McCreary and Thorn (610 - 690 K, 5) are also considered. There are twelve sublimation and eleven vaporizastion studies which lead to enthalpy of formation values showing excellent agreement, which the exception of two studies.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (6), is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels (for n<10) and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the levels listed above; the next excited state is at approximately 46745 cm^{-1} above the ground state. Although we list only a few electronic levels, all levels reported by Moore (6) are considered in the calculation. The reported uncertainty in S°(298.15 K) is due to uncertainties in he relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states
(n>10) and use of different fill and cutoff procedures (7).

The thermal functions at 298.15 K differ from the CODATA recommendations (1) for two reasons. First, the entropy differs by 0.1094 J K^{-1} mol^{-1} because this table uses a reference pressure of 1 bar, wheras CODATA recommendations are based on 1 atm. Second, small changes, ~0.004 J K^{-1} mol^{-1}, arise presumably due to the use of slightly different values for the fundamental constants.

ZINC, ION (Zn^+)

IDEAL GAS

M_r = 65.37945

$IP(Zn^+, g)$ = 144892.6 ± 2 cm^{-1}
$S°(298.15\ K)$ = 166.751 ± 0.02 J K^{-1} mol^{-1}

$\Delta_f H°(0\ K)$ = 1030.6 ± 0.84 kJ mol^{-1}
$\Delta_f H°(298.15\ K)$ = [1037.336] kJ mol^{-1}

Electronic Levels and Quantum Weights

State	ϵ_i, cm^{-1}	g_i
$^2S_{1/2}$	0.0	2
$^2P_{1/2}$	48480.6	2
$^2P_{1/2}$	49354.4	4

Enthalpy of Formation

$\Delta_f H°(Zn^+, g, 0\ K)$ is calculated from $\Delta_f H°(Zn, g, 0\ K)$ (1) using the spectroscopic value of IP(Zn) = 75768.10 ± 0.5 cm^{-1} (906.388 ± 0.006 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Zn^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Zn, g, 0\ K)$ by using IP(Zn) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for Zn(g), $Zn^+(g)$, and $e^-(g)$. $\Delta_f H°(Zn \rightarrow Zn^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by -6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The information on electronic energy levels and quantum weights, given by Moore (2, 6) is incomplete because many theoretically predicted levels have not been observed. Our calculations indicate that any reasonable method of filling in these missing levels and cutting off the summation in the partition function (7) has no effect on the thermodynamic functions to 6000 K. This is a result of the high energy of all levels other than the ground state and the first two excited states; the next excited state is 62721.9 cm^{-1} above the ground state. Since inclusion of these excited states has no effect on the thermodynamic functions (to 6000 K), we list only the ground state and the first two excited states. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative ionic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the excited states and use of different fill and cutoff procedures (7).

ZINC, ION (Zn^-) IDEAL GAS M_r = 65.38055

EA(Zn, g) = 0.9 ± 0.20 eV

$S°(298.15\ K) = 160.99 \pm 0.03\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 115.5 \pm 20\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [109.870]\ kJ\ mol^{-1}$

Electonic Level and Quantum Weight

State	ε_i, cm^{-1}	g_i
$^2S_{1/2}$	0	2

Enthalpy of Formation

$\Delta_f H°(Zn^-, g, 0\ K)$ is calculated from $\Delta_f H°(Zn, g, 0\ K)$ (1) using the adopted electron affinity of EA(Zn) = 0.09 ± 0.20 eV -0.67 ± 19.3 kJ mol^{-1}). This value is calculated by Zollwig (2) using a horizontal analysis technique for the ground state $3d^{10}4s^25s(^2S_{1/2})$. There is a possibility that the ground state may be $3d^{10}4s^24p\ (^2P_o)$ in which case Zollwig (2) calculated an electron affinity EA = -0.67 eV. Hotop and Lineberger (3), in a recent review, recommends that $Zn^-(g)$ has a metastable state, $4s4p^24p$, with EA>0 (2, 4). Additional information on Zn^- may be obtained in the critical discussions of Hotop and Lineberger (3, 4), Rosenstock et al. (6), and Massey (7); and in the articles by Gohel et al. (8) and Kaiser et al. (9).

$\Delta_f H°(Zn^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Zn, g, 0\ K)$ by using EA(Zn) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for $Zn^-(g)$, Zn(g), and $e^-(g)$. $\Delta_r H°(Zn^- + Zn + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al (6). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Zn^-(g)$ is that given by Zollwig (2). Lacking any experimental evidence as to the stability of any excited states, we assume that no stable states exist.

PREVIOUS: June 1979 (1 atm) CURRENT: June 1979 (1 bar)

$S°(298.15\ K) = 38.87 \pm 0.2\ J\ K^{-1}\ mol^{-1}$

$T_{trs} = 1135 \pm 10\ K$ (α-β)

$\Delta_f H°(0\ K) = 0\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = 0\ kJ\ mol^{-1}$

$\Delta_{trs} H° = 4.017 \pm 0.3\ kJ\ mol^{-1}$

Enthalpy of Formation

Zero by definition.

Heat Capacity and Entropy

The adopted thermal functions for α-Zr(cr) are derived from the studies of Collings and Ho (1), Wolcott (2), Burk et al. (3), Skinner and Johnston (4), Todd (5), and Scott (6). The mathematical and graphical treatment of these four studies yields a continuous and smooth heat capacity curve.

There are six studies (1, 2, 7 - 10) on the heat capacity of zirconium in the region 1-5 K. *Only Wolcott (2) reported the* experimental data (60 data points). In the other studies, an equation (with two constants) was given to describe the entire set of experimental data. The constants given by Collings and Ho (1) and the data of Wolcott (2) were used in this region. The maximum difference in the calculated values for $S°(5\ K)$ is 0.00029 cal $mol^{-1}\ K^{-1}$, with the adopted value being $S°(5\ K) = 0.0043$ cal $mol^{-1}\ K^{-1}$. Similarly for $Cp°(5\ K)$ the maximum difference is 0.00073 cal $mol^{-1}\ K^{-1}$, with the adopted value being $Cp°(5\ K) = 0.00610$ cal $mol^{-1}\ K^{-1}$.

In the region above 5 K and below 300 K, there are four heat capacity studies (2 - 5). There is much scatter among the different studies, between 150 and 300 K. From 150-200 K, we adopt graphically smoothed Cp values intermediate between Burk et al. (2), Skinner and Johnston (4), and Todd (5). From 200-300 K, we adopt the data of Skinner and Johnston (4), because it meshes better with the high temperature data. Burk's data is 1.4% higher than the adopted at 170 K, Todd's data is 0.7% higher and Skinner's data ia 1% lower. Todd's data is 3% higher than the adopted at 300 K.

Between 300 K and 1135 K there are three heat capacity studies (6, 11, 12) and seven enthalpy studies (13 - 19). *The three* heat capacity studies show much scatter and disagreement. The data of Scott (6) was adopted, although only the data from runs 17 and 64, out of a total of nine runs, was actually used in the fit. None of Scott's data below 540 K were used in the fit, becuase the data had a hump in this region and appeared to be high. *The region between the low temperature data (300 K) and 540 K* was graphically smoothed to assure continuity in the Cp curve. The data of Scott (6) is about 5% higher than the adopted between 300 and 540 K. Between 540 and 960 K it is within ±3% of the adopted. From 960 K to the transition temperature, there is much *scatter; some of the data are as much as 20% higher than the adopted.* The data of Vollmer et al. (12) are about 3% lower than the adopted at 300 K. Between 540 and 580 it agrees with the adopted. From 580-1000 K it is about 1.5% higher than the adopted. The data of Klein and Danielson (11) was given only as a graph. It is considerably lower than the adopted values.

The enthalpy studies show an unusually large scatter within each study, as well as a lack of agreement between the studies. When plotted as mean heat capacity, the seven studies are all higher than the adopted values, by 2 to 40%.

Transition Data

Refer to the β-Zr(cr) table for details.

Sublimation Data

There are no experimental sublimation studies involving α-Zr(cr). The enthalpy of sublimation is calculated as the difference between the enthalpy of formation of the monatomic gas and the enthalpy of formation of α-Zr(cr).

ZIRCONIUM, BETA (β-Zr) CRYSTAL A_r = 91.22

$S°(298.15\ K) = [43.192]\ J\ K^{-1}\ mol^{-1}$
$T_{trs} = 1135 \pm 10\ K\ (\alpha-\beta)$
$T_{fus} = 2125 \pm 15\ K\ (\beta-\ell)$

$\Delta_f H°(298.15\ K) = [4.810]\ kJ\ mol^{-1}$
$\Delta_{trs} H° = 4.017 \pm 0.3\ kJ\ mol^{-1}$
$\Delta_{fus} H° = 20.92 \pm 6.3\ kJ\ mol^{-1}$

Enthalpy of Formation

The enthalpy of formation is calculated from that of the α-crystal by addition of $\Delta_{trs}H°$ and the difference in enthalpy, H°(1135 K) - H°(298.15 K), between the α-crystal and the β-crystal.

Heat Capacity and Entropy

There are five heat capacity studies (1 - 5) and five enthalpy studies (6 - 10) over the temperature range 1135-2125 K. The adopted values were based on the heat capcity study of Cezairliyan and Righini (4). The data of Scott (1) showed much scatter with a maximum deviation of 7% from the adopted. The data of Rumyantsu et al. (5) were largely scattered and about 15% high. The data of Vollmer et al. (3) and of Klein and Danielson (2) were 5 - 10% lower than the adopted. The enthalpy studies show an unusually large scatter within each study, as well as lack of agreement between the studies. Like the α-Zr(cr), the mean heat capacities are all higher than the adopted values, by 3 to 10%. The entropy at 298.15 K is calculated in a manner similar to that for the enthalpy of formation.

Phase Data

Zirconium, at ambient pressures, exists in two crystal modifications. The low temperature form, α-Zr, is hexagonal close packed, an hcp (A3) structure isotypic with Mg. The high temperature form, β-Zr, is body centered cubic, a bcc (A2) structure.

Transition Data

The transition temperature and enthalpies of transition are summarized in the table below. The adopted value of T_{trs} is 1135±10 K. The adopted $\Delta_{trs}H°$ is 4.017 kJ mol^{-1}.

Source	T_{trs}/K	$\Delta_{trs}H°$, kcal mol^{-1}	Purity	Method

Fusion Data

Refer to the liquid table for details.

Sublimation Data

The sublimation studies involving β-Zr(cr) are summarized on the Zr(g) table. The enthalpy of sublimation for β-Zr(cr) is calculated as the difference in the enthalpies of formation at 298.15 K of Zr(g) and β-Zr(cr).

ZIRCONIUM (Zr) LIQUID A_r = 91.22

$S°(298.15\ K)$ = [47.605] J K^{-1} mol^{-1}

T_{fus} = 2125 ± 15 K

$\Delta_f H°(298.15\ K)$ = [17.404] kJ mol^{-1}

$\Delta_{fus}H°$ = 20.92 ± 6.3 kJ mol^{-1}

Enthalpy of Formation

The enthalpy of formation is calculated from that of the β-crystal by addition of $\Delta_{fus}H°$ and the difference in enthalpy, $H°(2125\ K) - H°(298.15\ K)$, *between the β-crystal and the liquid.*

Heat Capacity and Entropy

There are no heat capacity or enthalpy studies covering the liquid region of zirconium. A constant value of $C_p°$ = 41.84 J K^{-1} mol^{-1} is assumed for the region 2125-5500 K. A glass transition is assumed at 1580 K below which extrapolated β-Zr heat capacity values are used. The entropy is calculated in a manner similar to that used for the enthalpy of formation.

Fusion Data

The available fusion temperature and enthalpy of fusion data are summarized in the table below. We adopt T_{fus} = 2125 ± 15 K and $\Delta_{fus}H°$ = 20.92 ± 6.3 kJ mol^{-1}.

Source	T_{fus}/k	$\Delta_{fus}H°$, kcal mol^{-1}

Elyutin et al (10)		5.0 ± 0.3
Ackerman and Rauk (11)	2134	
Martynyuk and Tsapkov (12)		5.139

Vaporization Data

The vaporization studies are summarized on the Zr(g) table. The boiling point is calculated as that temperature for which $\Delta_r G°$ = 0 for Zr(ℓ) = Zr(g). $\Delta_{vap}H°$ is the corresponding enthalpy change. T_{vap} is the temperature at which the fugacity is one bar.

Enthalpy of Formatiom

Vapor pressures over Zr(β) and Zr(ℓ) were measured, using the Langmuir free-vaporization method, by Zwikker (1), Skinner et al. (2), Fidorov and Smirnov (3, 4) and Koch and Anable (5). Trulson and Goldstein (6) used a mass spectrometric method with a high temperature Knudson effusion source to obtain the vapor pressure for Zr(β) and Zr(ℓ). Similarly, Ackermann and Rauh (7) determined the vapor pressure for Zr(ℓ) by a combination of mass effusion and mass spectrometric techniques. In this latter study the reported values (equation only) were obtained from vapor pressure measurements over Zr(ℓ) saturated with tungsten. These values were then corrected for the dissolved tungsten by the corresponding mole fraction.

A plot of log p vs 1/T for the above mentioned studies reveals considerable discrepancy. The results of Fredorov and Smirnov (3, 4) are an order of magnitude higher than those of Zwikker (1); however, both studies appear inconsistent with the other studies involving Zr(β) (2, 6, 7). The sublimation studies of Golubtsov et al. (9) and Sumin and Peizularz (10) reported $\Delta_f H°(0\ K)$ values of 143.1 ± 0.22 and 145.6 ± 0.4 kcal mol^{-1}, respectively. The experimental data is not given in either study.

A second and third law evaluation of seven studies yields an adopted enthalpy of formation value, $\Delta_f H°(298.15\ K, Zr, g)$ = 145.8 ± 2.0 kcal mol^{-1}. This adopted value is a weighted average of four vapor pressure studies (2, 5, 6, 7). Hultgren (8), using different thermodynamic functions and data available through 1967, recommended a enthalpy of foramtion (at 298.15 K) of 145.5 ± 1.0 kcal mol^{-1}, based primarily on the data of Skinner et al. (2).

Reactions: a. Zr(β) = Zr(g) b. Zr(ℓ) = Zr(g)

Heat Capacity and Entropy

The electronic energy levels are given in the compilation by Moore (11, 12). Although we have only listed the ground state, first two excited states, the highest observed excited state, and the ionization limit for Zr(g), all levels listed by Moore (11, 12), as well as estimated missing levels for n = 5 and 6, are used in our calculations. The observed levels are too numerous to list completely. Our calculations indicate that for Zr(g) the thermochemical functions are independent of the estimated missing levels for n = 5 and 6 (levels estimated and included above 52000 cm^{-1}) and the cut-off procedure up to 4000 K. The Gibbs energy function is essentially unaffected (<0.001 kcal mol^{-1}) up to 6000 K. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the more exact estimation of excited states for n = 5 and 6, the consideration of states for n > 6, and the utilization of proper fill and cut-off procedures (13).

Enthalpy of Formation

$\Delta_f H°(Zr^+, g, 0\ K)$ is calculated from $\Delta_f H°(Zr, g, 0\ K)$ (1) using the spectroscopic value of IP(Zr) = 55145 ± 5 cm^{-1} (659.68 ± 0.06 kJ mol^{-1}) from Moore (2). The ionization limit is converted from cm^{-1} to kJ mol^{-1} using the factor, 1 cm^{-1} = 0.01196266 kJ cm^{-1}, which is derived from the 1973 CODATA fundamental constants (3). Rosenstock et al. (4) and Levin and Lias (5) have summarized additional ionization and appearance potential data.

$\Delta_f H°(Zr^+, g, 298.15\ K)$ is calculated from $\Delta_f H°(Zr, g, 0\ K)$ by using IP(Zr) with JANAF (1) enthalpies, H°(0 K) - H°(298.15 K), for Zr(g), $Zr^+(g)$, and $e^-(g)$. $\Delta_f H°(Zr \rightarrow Zr^+ + e^-, 298.15\ K)$ differs from a room temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (4). $\Delta_f H°(298.15\ K)$ should be changed by $^-6.197$ kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The electronic energy levels are given in the compilations by Moore (2, 6). Although we have only listed the ground state, first three excited states, the highest observed excited state, and the ionization limit for $Zr^+(g)$, all levels listed by Moore (2, 6), as well as estimated missing levels for n = 5 and 6, are used in our calculations. The observed levels are too numerous to list completely. Our calculations indicate that for $Zr^+(g)$ the thermochemical functions are independent of the estimated missing levels for n = 5 and 6 (levels estimated and included above 90000 cm^{-1}) and the cut-off procedure up to 6000 K. The Gibbs energy function is essentially unaffected (<0.001 cal mol^{-1} K^{-1})) up to 12000 K. The reported uncertainty in S°(298.15 K) is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the more exact estimation of excited states for n = 5 and 6, the consideration of states for n>6, and the utilization of proper fill and cut-off procedures (7).

PREVIOUS: June 1979 (1 atm) CURRENT: March 1984 (1 bar)

ZIRCONIUM, ION (Zr^-) IDEAL GAS M_r = 91.22055

EA(Zr, g) = 0.426 ± 0.014 eV

$S°(298.15\ K) = 185.762 \pm 0.001\ J\ K^{-1}\ mol^{-1}$

$\Delta_f H°(0\ K) = 568.92 \pm 1.5\ kJ\ mol^{-1}$

$\Delta_f H°(298.15\ K) = [564.979]\ kJ\ mol^{-1}$

Electonic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^4F_{3/2}$	0.0	4
$^4F_{5/2}$	250	6
$^4F_{7/2}$	580	8
$^4F_{9/2}$	950	10

Enthalpy of Formation

$\Delta_f H°(Zr^-, g, 0\ K)$ is calculated from $\Delta_f H°(Zr, g, 0\ K)$ (1) using the adopted electron affinity of EA(Zr) = 0.426 ± 0.014 eV (41.102 ± 1.351 kJ mol^{-1}). This value, recommended by Hotop and Lineberger (2), is based on a laser photodetachment electron spectrometry study (3). Additional information on $Zr^-(g)$ may be obtained in the critical discussions of Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6).

$\Delta_f H°(Zr^-, g, 298.15\ K)$ is obtained from $\Delta_f H°(Zr, g, 0\ K)$ by using EA(Zr) with JANAF (1) enthalpies, $H°(0\ K) - H°(298.15\ K)$, for $Zr^-(g)$, Zr(g), and $e^-(g)$. $\Delta_r H°(Zr^- \rightarrow Zr + e^-, 298.15\ K)$ differs from a room-temperature threshold energy due to inclusion of these enthalpies and to threshold effects discussed by Rosenstock et al. (5). $\Delta_f H°(298.15\ K)$ should be changed by +6.197 kJ mol^{-1} if it is to be used in the ion convention that excludes the enthalpy of the electron.

Heat Capacity and Entropy

The ground state electronic configuration for $Zr^-(g)$ is given by Hotop and Lineberger (2, 4), Rosenstock et al. (5) and Massey (6). The fine structure separation has been calculated by an isoelectronic extrapolation of ratios of fine struture separations and is that recommended by Hotop and Lineberger (2).
