

Standard Thermodynamic Functions of Some Isolated Ions at 100–1000 K

A. Loewenschuss and Y. Marcus

Department of Inorganic and Analytical Chemistry, Hebrew University of Jerusalem, Jerusalem 91904, Israel

Received April 22, 1996; revised manuscript received June 27, 1996

The standard thermodynamic functions (C_p° , S° , H° and $(G^\circ - H_0^\circ)/T$) at 100 to 1000 K of 24 polyatomic gaseous ions are reported, based on structural and spectroscopic data from the literature. These ions supplement the 130 ions previously studied and are: zirconyl, hydrotelluride, amide, selenocyanate, tellurocyanate, orthoborate, metaphosphate, arsenite, orthosilicate, tetrachloropalladate(II), tetrabromopalladate(II), tetrachloroplatinate(II), tetrabromoplatinate(II), hexafluorophosphate, hexafluoroarsenate, hexafluoroantimonate, hexabromoplatinate(IV), tetracyanonickelate, tetracyanomercurate, octacyanomolybdate(IV), sulfamate, benzoate, guanidinium, and glycine as cation, zwitterion, and anion. © 1996 American Institute of Physics and American Chemical Society.

Key words: bond lengths and angles; enthalpy of ions; entropy of ions; Gibbs energy function of ions; heat capacity of ions; isolated ions; thermodynamic functions; vibrational spectra.

1. Introduction

The standard thermodynamic functions (C_p° , S° , H° and $(G^\circ - H_0^\circ)/T$) at 100 to 1000 K of more than 130 polyatomic gaseous ions were reported by us several years ago.¹ These were based on structural and vibration-spectroscopic data obtained from the literature (or estimated where necessary) and

summarized either in that publication, or in a previous one dealing with the entropies S° at 298.15 K only.² We have now calculated such functions for an additional 24 polyatomic gaseous ions, based on similar data summarized and discussed in the present paper.

The explicit statistical-thermodynamic expressions required for the calculations were presented previously.¹ They were based on the ideal gas approximation and assume the separability of the translational, vibrational, and rotational degrees of freedom, hence the additivity of their contributions. The electronic contributions could be neglected for all the species considered here, since the ground state electronic level is not degenerate and excited levels are too high to contribute significantly. The ideal models of a rigid rotor and harmonic oscillator were used for the rotational and vibrational degrees of freedom. These assumptions may impose the upper temperature boundary of 1000 K to the validity of the calculations. The tabulated values pertain to the pressure of 0.101325 MPa, in order to conform to the previous publications.^{1,2} Changing over to the standard pressure of 0.1 MPa increases the entropy and the Gibbs free energy function by $R \ln 1.01325 = 0.109442 \text{ J K}^{-1} \text{ mol}^{-1}$ for all species and temperatures. The heat capacity and enthalpy are not affected.

As before, structural data, bond lengths and angles from (mainly x-ray) diffraction studies of crystalline compounds, are taken to represent the structure of the gaseous ions for the purpose of the calculation of the rotational contributions to the thermodynamic functions. The vibrational-spectroscopic data of species in solution (mainly from Raman spectroscopy), nearer in their nature to isolated ions, are preferred where available over those for ionic species in solids (from both Raman and infrared spectra), due to the latter being prone to solid state effects. These may be symmetry constraints imposed by the crystal lattice and polarization by neighboring counter-ions. The phase for which the spectroscopic data used for the calculation pertain is stated for each species.

The present choice of ions is being made with the view to supplementing the species of similar structures previously considered, but it is limited by the structural and even more so by the spectroscopic information available in the literature. For an N -atomic ion, $3 \times N - 6$ vibrations are required for non-linear species and $3 \times N - 5$ for linear species, although some are degenerate if a rotational axis of $C_{n>2}$ characterizes the symmetry of the ion. This places a practical limit on the size of N that can be considered in calculations of this kind. The type of vibration (A, B, E or T) is indicated for describing the degeneracy (1, 1, 2, and 3, respectively), without giving more details of the assignment, since there is often not agreement among different authors. Free rotation of one part of the molecule against the other is assumed not to take place if there is experimental evidence for a frequency assigned to the torsional mode of the bond in question. Also, a configuration of maximal symmetry is selected, if it does not contradict structural (x-ray diffraction) data.

It is not claimed that the ions for which calculations are

performed are necessarily stable in the gas phase; certainly not over the entire temperature range up to 1000 K. Such calculated values can still serve as the basis for calculations of solvation and reaction thermodynamics, and as such have been found valuable in the past.

2. Results for Isolated Ions

2.1 Diatomic Ions

(1) *Zirconyl*, ZrO^{2+} : Crystalline compounds expected to involve discrete ZrO^{2+} groups are possibly ZrOF_2 and $\text{ZrO}(\text{SbF}_6)_2$. In the former,³ distances $r(\text{Zr-O})=0.204$ to 0.226 nm and a stretching frequency of the Zr-O bond of $\nu=864 \text{ cm}^{-1}$ were reported, while for the latter $\nu=877 \text{ cm}^{-1}$ was reported.⁴ The sensitivity of the resulting thermodynamic functions to the variation in the frequency is negligible (0.2% in S° at 1000 K), whereas variation of the distance has a somewhat larger effect (~1% in S° at 1000 K). Table 1 reports the data for $r=0.204$ nm and $\nu=864 \text{ cm}^{-1}$.

(2) *Hydrotelluride*, TeH^- : The distance $r(\text{Te-H})$ is expected to be the sum of the single bond radii given by Pauling⁵ as 0.138 nm for Te and 0.030 nm for H, i.e., $r=0.168$ nm. The vibrational frequency of the bond was reported⁶ as $\nu=1975 \text{ cm}^{-1}$ in solid $(\text{C}_6\text{H}_5)_4\text{PTeH}$. The thermodynamic functions are reported in Table 2. The vibrational contribution to the thermodynamic functions is negligibly small, so that any variation in it is of no consequence.

2.2 Triatomic Ions

(3) *Amide*, NH_2^- : Botschwina⁷ calculated with high precision the structure and the vibrational spectrum of the isolated amide anion. The distances in this bent ion of C_{2v} symmetry

are $r(\text{N-H})=0.1030$ nm, the angle $\angle \text{HNH}=102.0^\circ$, and the frequencies are 3107.5 (A), 3163.8 (A), and 1462.5 (A) cm⁻¹. The calculated thermodynamic functions are reported in Table 3. Due to the high frequencies (energies), the vibrational contributions to the thermodynamic functions are small. The uncertainty in the rotational contribution, due to a slightly larger $\angle \text{HNH}=104^\circ$,⁸ is also very small.

(4) *Selenocyanate*, SeCN⁻: The structure of this linear ion, discussed by Nagarajan and Hariharan⁹ with respect to

the vibrational spectrum, was taken from Sutton's tables¹⁰; $r(\text{Se-C})=0.1709$ nm and $r(\text{C-N})=0.1153$ nm. The frequencies⁹ are those reported by Greenwood *et al.*: 2079 (A), 535 (A) and 426 (E) cm⁻¹ for solid KSeCN.¹¹ The resulting thermodynamic functions are reported in Table 4. Since the (doubly degenerate) bending and the Se-C stretching frequencies are fairly low, the variability due to other reported frequencies in solid KSeCN ought to be considered. Ti and Kettle¹² reported 419 and 427 cm⁻¹ (bending) and 563 cm⁻¹ (Raman), and Bürger and Schmid¹³ reported 420.5 and 430.7 (bending) and 563.4 cm⁻¹ (infrared). In comparison to the former set, the latter set of frequencies produces an S° value larger by 0.24 and a C_p° value larger by 0.25 J K⁻¹ mol⁻¹ at 298.15 K. The differences are hardly significant.

(5) *Tellurocyanate*, TeCN⁻: As was the case for selenocyanate, Nagarajan and Hariharan⁹ quoted data by Sutton¹⁰ and Greenwood *et al.*,¹¹ and no other data were found. The distances are $r(\text{Te-C})=0.1904$ nm, $r(\text{C-N})=0.1153$ nm and the frequencies are 2086 (A), 459(A), and 403 (E) cm⁻¹ for KTeCN. The resulting thermodynamic functions are reported in Table 5.

Our previous publication² reported S° (298 K) of cyanate as 218.9 and of thiocyanate as 232.5 J K⁻¹ mol⁻¹, arising from $r(\text{O-C})=0.113$ and $r(\text{C-N})=0.127$ nm (or, probably, vice versa) for cyanate and $r(\text{S-C})=0.161$ and $r(\text{C-N})=0.117$ nm. In view of other reported $r(\text{C-N})$ values, 0.127 nm appears to be excessively large. The rotational partition function is not sensitive to the reversal of the O-C and C-N distance values in this case. If, instead, the values quoted by Nagarajan and Hariharan⁹ from Sutton's tables¹⁰ are used along with Greenwood's¹¹ frequencies, the entropies become 218.69 and 233.46 J K⁻¹ mol⁻¹, respectively.

2.3. Tetraatomic Ions

(6) *Orthoborate*, BO_3^{3-} : This planar, trigonal ion, of D_{3h} symmetry, has distances^{5,14} $r(\text{B}-\text{O})=0.136$ nm. There are two A-type and two E-type vibrations, with a corresponding set of frequencies in solid borates:¹⁴ 939 and 712 and 1285 and 604 cm⁻¹, respectively. The resulting thermodynamic functions are reported in Table 6. The most recently published set of frequencies¹⁵ (borate in KBr crystals) is 949 (A), 736 (A), 1222 and 1247 (E), and 582(E) cm⁻¹ (the

former E-type vibration has lost its degeneracy due to constraints in the crystal). Using these causes only a slight change in the thermodynamic functions.

(7) *Metaphosphate*, PO_3^- : This ion generally appears in condensed states, but it has sometimes been referred to in the literature as a discrete species. It has C_{3v} symmetry, i.e., it is trigonal-pyramidal, with the angle $\angle \text{OPO}$ being 110° and the bond length $r(\text{P}-\text{O})=0.176$ nm.⁵ A set of vibrational frequencies was reported by Nagarajan for solid metaphosphates:¹⁶ 982 (A), 551 (A), 1029 (E), and 458 (E) cm⁻¹. The resulting thermodynamic functions are reported in Table 7. No other data were found.

(8) *Arsenite*, AsO_3^{3-} : This trigonal-pyramidal ion with symmetry C_{3v} is stable in both the crystalline and solution states, and has a bond distance $r(\text{As}-\text{O})=0.184$ nm with the angle $\angle \text{OAsO}$ being 110°.⁵ Two sets of vibrational frequencies have been published. Nagarajan¹⁶ reported 752 (A), 340 (A), 680 (E) and 340 (E) cm⁻¹ whereas Loehr and Plane^{16(a)} gave for these vibrations 770, 325, 815, and 265 cm⁻¹, respectively. The latter set, from Raman spectra of aqueous solutions, yielded the thermodynamic functions reported in Table 8, the vibrational entropy being 2.5 J K⁻¹ mol⁻¹ larger and the vibrational heat capacity 0.9 J K⁻¹ mol⁻¹ lower at 298.15 K than for the former set of frequencies. These differences diminish with increasing temperatures.

2.4. Pentaatomic Ions

(9) *Orthosilicate*, SiO_4^{4-} : This ion exists mainly in the condensed state, but has been referred to as an individual species in the literature, with tetrahedral symmetry (T_d) and $r(\text{Si}-\text{O})=0.163$ nm.¹⁷ Two sets of vibration frequencies have been reported: Rawat *et al.*¹⁸ gave 842 (A), 444 (E), 972 (T),

and 540 (T) cm^{-1} , whereas Mueller and Nagarajan¹⁹ gave 819, 340, 956, and 527 cm^{-1} , respectively. The former, more recent set for a solid silicate, yielded the thermodynamic functions reported in Table 9. The difference between the lowest frequencies reported is of most significance for the calculated vibrational contribution to the thermodynamic functions. The latter set of frequencies provides 3.8 $\text{J K}^{-1} \text{mol}^{-1}$ more to the entropy and 2.6 $\text{J K}^{-1} \text{mol}^{-1}$ more to the heat capacity at 298.15 K.

(10) *Tetrachloropalladate(II)*, PdCl_4^{2-} : This square planar ion, with symmetry D_{4h} , has been studied by many authors. The bond distance is $r(\text{Pd-Cl})=0.231 \text{ nm}$.⁵ One of the frequencies (generally designated as ν_5 , of B-type) is not active in either the Raman or the infrared spectra, whereas three frequencies appear in the Raman and three in the infrared spectra, with no coincidences, due to the existence of an inversion center. The most complete set (also for other tetrahalometallates) was that given by Goggin and Mink:²⁰ 303 (A), 275 (B, ν_2), 164 (B) cm^{-1} from Raman spectra of aqueous PdCl_4^{2-} , and 150 (A), 317 (E) and 167 (E) cm^{-1} from infrared spectra of solid $[(\text{C}_4\text{H}_9)_4\text{N}]_2\text{PdCl}_4$, is used for the present calculations to generate the results shown in Table 10. The missing frequency is estimated, following the suggestion of Nakamoto,²¹ as $\nu_5=\nu_2/2^{1/2}=194 \text{ cm}^{-1}$, which is consistent with earlier work² for similar octahedral species. Alternative sets of frequencies were reported by Hendra,²² Durig and Nagarajan,²³ Perry *et al.*,²⁴ and Bosworth and Clark.²⁵ The difference in the entropy due to using these different sets of frequencies is up to 7.5 $\text{J K}^{-1} \text{mol}^{-1}$, independent of the temperature. Due to the low frequencies involved, this uncertainty is quite significant and similar differences would be noted also in the other thermodynamic functions.

(11) *Tetrabromopalladate(II)*, PdBr_4^{2-} : This ion is completely analogous to the chloro-complex, with the bond distance $r(\text{Pd-Br})=0.2444 \text{ nm}$ from x-ray diffraction data.²⁶ The frequency set given by Goggin and Mink²⁰: 188 (A), 172 (B, ν_2), 102 (B) cm^{-1} from Raman spectra of aqueous PdBr_4^{2-} and 114 (A), 243 (E), and 104 (E) cm^{-1} from infrared spectra of solid $[(\text{C}_4\text{H}_9)_4\text{N}]_2\text{PdBr}_4$, was again employed for the calculations, with results shown in Table 11. The missing frequency was estimated as above: $\nu_5=\nu_2/2^{1/2}$

$= 117 \text{ cm}^{-1}$. The difference in the entropy due to the different frequencies reported by Hendra,²² Durig and Nagarajan,²³ Perry *et al.*,²⁴ and Bosworth and Clark²⁵ is up to $8.0 \text{ J K}^{-1} \text{mol}^{-1}$.

(12) *Tetrachloroplatinate(II)*, PtCl_4^{2-} : This ion is also completely analogous to the palladium complex, with the bond distance $r(\text{Pt-Cl})=0.231 \text{ nm}$.⁵ The frequency set given by Goggin and Mink:²⁰ 330 (A), 171 (B, ν_2), 312 (B) cm^{-1} from Raman spectra of aqueous PtCl_4^{2-} and 147 (A), 309 and 325 (E), and 167 (E) cm^{-1} from infrared spectra of solid $[(\text{C}_4\text{H}_9)_4\text{N}]_2\text{PtCl}_4$, was again employed for the calculations, with results shown in Table 12. The missing frequency could be estimated as above: $\nu_5 = \nu_2/2^{1/2} = 121 \text{ cm}^{-1}$. However, the value found²⁰ for the analogous and isoelectronic ion AuCl_4^- , 112 cm^{-1} , was preferred, since the central atom does not move in the mode in question, hence its mass does not affect the vibrational frequency. Indeed, the even lower value of $\nu_5 = 71 \text{ cm}^{-1}$ was reported by Yeranos,²⁷ but this may well be a lattice mode. Alternative sets of frequencies reported by Hendra,²² Durig and Nagarajan,²³ Perry *et al.*,²⁴ and Bosworth and Clark²⁵ cause differences in the entropy up to $10.0 \text{ J K}^{-1} \text{mol}^{-1}$.

(13) *Tetrabromoplatinate(II)*, PtBr_4^{2-} : This ion is also completely analogous to the palladium complex, with the bond distance $r(\text{Pt-Br})=0.246 \text{ nm}$, obtained from the single bond differences Pt-Cl, Pd-Cl, and $r(\text{Br}) - r(\text{Cl})$.⁵ The frequency set given by Goggin and Mink:²⁰ 208 (A), 106 (ν_2 , B), 194 (B) cm^{-1} from Raman spectra of aqueous PtBr_4^{2-} and 104 (A), 225 (E), and 112 (E) cm^{-1} from infrared spectra of solid $[(\text{C}_4\text{H}_9)_4\text{N}]_2\text{PtBr}_4$, was again employed for the calculations, with results shown in Table 13. The missing frequency was estimated as above: $\nu_5 = \nu_2/2^{1/2} = 88 \text{ cm}^{-1}$. Alternative sets of frequencies reported by Hendra,²²

Durig and Nagarajan,²³ Perry *et al.*,²⁴ and Bosworth and Clark²⁵ cause differences in the entropy of up to $8.7 \text{ J K}^{-1} \text{mol}^{-1}$.

2.5. Octahedral Heptaatomic Ions

(14) *Hexafluorophosphate*, PF_6^- : This ion, with symmetry O_h , has a bond distance $r(\text{P-F})=0.164 \text{ nm}$ according to Gillespie and Robinson.²⁸ An older estimate, 0.158 nm ,²⁹

1000	153.01	1.057	491.32	121.82	369.61

appears to be too low in view of the sum of the reported single bond radii.⁵ The set of vibrational frequencies given by Bougon *et al.*:³⁰ 746 (A, ν_1), 561 (E, ν_2), 475 (T, ν_5), from Raman spectra of solutions in HF and 817 (T, ν_3), 557 (T, ν_4), and 316 (T, ν_6) cm^{-1} from infrared spectra of crystalline $\text{ClO}_4^+ \text{PF}_6^-$, was used for the calculations, with results shown in Table 14.

The frequency ν_6 , that ought to be missing in a centrosymmetric ion, was nevertheless reported, because of slight deformation of the octahedron in the solid phase. However, the anion frequencies did not deviate much from solid to solution. If ν_6 is taken, as before,^{2,21} as $\nu_6 = \nu_5/2^{1/2} = 394 \text{ cm}^{-1}$, then it agrees with the calculated assignment by Aleksandrovskaia *et al.*,³¹ $\nu_6 = 402 \text{ cm}^{-1}$. The frequencies given by other authors^{29,32} do not differ enough to produce significant changes in the thermodynamic functions, but the variation in ν_6 produces a difference in these functions, e.g., the entropy at 298.15 K is $4.4 \text{ J K}^{-1} \text{mol}^{-1}$ larger with the smaller frequency value.³⁰

(15) Hexafluoroarsenate, AsF_6^- : This ion is completely analogous to hexafluorophosphate, with the bond distance $r(\text{As}-\text{F}) = 0.175 \text{ nm}$ being taken again from Gillespie and Robinson.²⁸

The difference between this and the alternative, $r(\text{As}-\text{F}) = 0.172 \text{ nm}$ ³² is insignificant, but the value 0.182 nm given by Begun and Rutenberg²⁹ is much too large, in view of the sum of the single bond radii.⁵ The set of frequencies reported by Bougon *et al.*:³⁰ 682 (A, ν_1), 568 (E, ν_2), 369 (T, ν_5), 696 (T, ν_3), 379 (T, ν_4), and 248 (T, ν_6) cm^{-1} , from Raman spectra of solutions and infrared spectra of solids as noted for PF_6^- , was again used for the calculations.

The value of ν_6 was only estimated, other estimates being 263²⁹ and 232³¹ cm^{-1} , while the present estimate^{2,21} ν_6

$= \nu_5/2^{1/2}$ is 268 cm^{-1} . The resulting thermodynamic functions are reported in Table 15. Other more or less complete sets of frequencies have been reported,^{29,31-33} but as far as the thermodynamic functions are concerned, they differ significantly only with respect to ν_6 . The entropy at 298.15 K is $1.7 \text{ J K}^{-1} \text{mol}^{-1}$ lower if 268 cm^{-1} is used for ν_6 instead of 248 cm^{-1} .

(16) Hexafluoroantimonate, SbF_6^- : This ion is analogous to the hexafluorophosphate and -arsenate ions, with a bond distance of $r(\text{Sb}-\text{F}) = 0.1844 \text{ nm}$ according to Kruger *et al.*³⁴ This is essentially the same value as given by Begun and Rutenberg, 0.1847 nm .²⁹ Here also the frequency set of Bougon *et al.*:³⁰ 653 (A, ν_1), 561 (E, ν_2), 273 (T, ν_5), 667 (T, ν_3), 280 (T, ν_4) and 190 (T, ν_6) cm^{-1} , as noted above for PF_6^- , was used for the calculations, with results shown in Table 16.

The uncertainty in ν_6 is again large, the minimal value being 174 cm^{-1} from the estimate by Aleksandrovskaia *et al.*,³² and the maximal value being 252 cm^{-1} , reported by Mohammed and Sherman,³⁵ for SbF_6^- isolated in a rubidium bromide crystal at a site symmetry of D_{2h} . The present estimate, $\nu_6 - \nu_5/2^{1/2} = 197 \text{ cm}^{-1}$, is consistent with the assignment of Bougon *et al.*³² Most of the other frequencies reported^{29,31-33} agree with the set of Bougon *et al.*,³⁰ also. These alternative values of ν_6 could produce a variation of $8.5 \text{ J K}^{-1} \text{mol}^{-1}$ in the entropy, independent of the temperature, and corresponding changes in the other thermodynamic functions.

(17) Hexabromoplatinate(IV), PtBr_6^{2-} : This octahedral ion, symmetry O_h , has a bond distance of $r(\text{Pt}-\text{Br}) = 0.2481 \text{ nm}$ according to Grundy and Brown.³⁶ Essentially complete sets of frequencies have been reported by Debeau and Kransman,³⁷ Debeau and Poulet,³⁸ Pandey *et al.*,³⁹ and

2.6. More Complicated Ions

(18) *Tetracyanonickelate (II)*, $\text{Ni}(\text{CN})_4^{2-}$: This is a square planar ion of symmetry D_{4h} , with bond lengths $r(\text{Ni-C})=0.187 \text{ nm}$ and $r(\text{C-N})=0.116 \text{ nm}$.⁴¹ A complete set of frequencies was reported by McCullough *et al.*⁴² from the infrared spectrum of solid $\text{Na}_2\text{Ni}(\text{CN})_4$, including estimates for a few which remained unobserved. This set comprises 11 non-degenerate (A- and B-type) vibrations: 2149, 419, 325, 2141, 405, 488, (91), 448, (77), (303), and 54 cm^{-1} and 5 doubly-degenerate (E-type) vibrations: 2132, 543, 433, (78), and 280 cm^{-1} ; the estimated values are in parentheses. The resulting thermodynamic functions are shown in Table 18.

(19) *Tetracyanomercurate(II)*, $\text{Hg}(\text{CN})_4^{2-}$: This is a tetrahedral ion of symmetry T_d , with a bond length of $r(\text{Hg-C})=0.222 \text{ nm}$ ⁴³ (and $r(\text{C-N})=0.116 \text{ nm}$, as above). A complete set of frequencies was reported by Jones,⁴³ although, here too, a few had to be estimated, since they were not observed in their infrared spectrum of solid $\text{K}_2\text{Hg}(\text{CN})_4$. The frequencies are: 2149 (A), 335 (A), (245) (E), (63) (E), 2146 (T), 330 (T), 233 (T), 54 (T), and 180 (T) cm^{-1} , with estimated values in parentheses. The resulting thermodynamic functions are shown in Table 19.

(20) *Octacyanomolybdate(IV)*, $\text{Mo}(\text{CN})_8^{4-}$: The structure of this ion has been the subject of controversy. Earlier reports considered the aqueous ion to be an archimedean anti-prism, of symmetry D_{4d} ,^{44,45} based on vibration-spectroscopic evidence. The D_{4d} symmetry was also said to be consistent with ^{13}C NMR data in solution, in which the single line observed indicates that all the ligands are equivalent.⁴⁶ Later reports, however, considered the aqueous ion to be a dodecahedron, of D_{2d} symmetry.^{47,48} All the authors agree that crystalline $\text{K}_4\text{Mo}(\text{CN})_8 \cdot 2\text{H}_2\text{O}$ possesses the

D_{2d} symmetry. This symmetry, on the other hand, is consistent with ^{95}Mo NMR line widths in aqueous $\text{Mo}(\text{CN})_8^{4-}$ -containing solutions.⁴⁹ Suggestions concerning the isolated ("gaseous") ion $\text{Mo}(\text{CN})_8^{4-}$ are also in disagreement: D_{4d} ⁴⁵ and D_{2d} .⁴⁷

The bond distances, $r(\text{Mo-C})=0.2163$ and $r(\text{C-N})=0.1156$ nm, and two sets of 4 angles φ $\text{CMoC}=69.1^\circ$ and 145.6° , were given in a paper reporting a complete set of calculated frequencies, for the D_{2d} (dodecahedron) symmetry.⁴⁸ These computed frequencies are in general agreement with the Raman and/or infrared spectra. These frequencies are: 2138, 2116, 568, 478, 419, 387, 331, 324, 152, 120, 116 (all A-type), 2117 (twice), 519, 486, 437, 381, 337, 328, 156, 133, 101, 52 (all B-type), 2116 (twice), 616, 463, 403, 362, 328, 321, 173, 136, 86 (all E-type, doubly degenerate) cm^{-1} . This information was considered by us the most reliable basis for the calculation of the thermodynamic functions shown in Table 20.

For the purpose of the calculation of thermodynamic functions, the configuration of the isolated ion is relevant to the rotational contributions with regard to the symmetry number: 4 for D_{2d} vs 8 for D_{4d} symmetries. The higher symmetry implies lower entropy and Gibbs function values by $R \ln 2 = 5.8 \text{ J K}^{-1} \text{mol}^{-1}$.

(21) *Sulfamate*, H_2NSO_3^- : This ion was assigned a C_s symmetry, with the hydrogen atoms not being in the plane defined by the nitrogen, sulfur, and any of the oxygen atoms.⁵¹ The set of distances and angles⁵¹ obtained for KH_2NSO_3 : $r(\text{S-N})=0.1666$, $r(\text{S-O})_{\text{mean}}=0.1457$, $r(\text{N-H})_{\text{mean}}=0.1007$ nm, $\varphi \text{ HNH}=110.2^\circ$, $\varphi \text{ HNS}=110.2^\circ$, $\varphi \text{ NSO}=116.1^\circ$, $\varphi \text{ OSO}_{\text{mean}}=113.8^\circ$, and $\varphi \text{ SNO}=105.2^\circ$, is used in the calculations. The free or hindered rotation of the $-\text{NH}_2$ group with respect to the $-\text{SO}_3$ group, is of significance

for the thermodynamic function calculations. For this ion, the barrier to free rotation was found to be high: 1083⁵² or $1370^{50} \text{ cm}^{-1}$ ($1 \text{ cm}^{-1}=11.96 \text{ J mol}^{-1}$), so that a torsional vibration was assigned instead, at 266 cm^{-1} ,⁵⁰ in agreement with inelastic neutron scattering (267 cm^{-1}).⁵³ The other vibrational frequencies obtained for solid KH_2NSO_3 are at: 3295, 3270, 1600, 1565, 1244, 1194, 1130, 1054, 995, 800, 594, 561, 406, and 364 cm^{-1} (all A-type),⁵⁰ in good agreement with the data of others.⁵³⁻⁵⁶ The resulting thermodynamic functions are shown in Table 21.

It is of interest to compare the sulfamate ion with sulfamic acid, the zwitterion protonated form, $^+\text{H}_3\text{NSO}_3^-$. The rotational barrier is somewhat lower, 945⁵⁷ or 953^{52} cm^{-1} , leading to a somewhat lower torsional frequency, 250 cm^{-1} at 300 K (275 cm^{-1} at 74 K).^{57,58} The extra hydrogen atom is responsible for an additional stretching frequency ($\sim 3200 \text{ cm}^{-1}$) and two additional bending frequencies (~ 1000 and $\sim 1600 \text{ cm}^{-1}$). These high frequencies have little effect on the thermodynamic functions. However, the greater bond length $r(\text{S-N})=0.1764$ nm⁵² does make a difference in the symmetric stretching frequency (678 instead of 809 cm^{-1}) and to the rotational contributions to these functions (the other structural data are nearly the same). Also, the symmetry number of the C_{3v} zwitterion is 3 rather than 1 of the anion, leading to $R \ln 3=9.1 \text{ J K}^{-1} \text{mol}^{-1}$ lower entropy and Gibbs function.

(22) *Benzoate*, $\text{C}_6\text{H}_5\text{CO}_2^-$: this flat symmetrical ion has symmetry C_{2v} . The relevant distances, $r(\text{C-C})_{\text{ar}}=0.1397$, $r(\text{C-C})=0.1504$, $r(\text{C-O})=0.125$, and $r(\text{C-H})=0.1084$ nm, and the angles, which are all 120° except $\varphi \text{ OCO}=125.5^\circ$, are from Pauling,⁵ the carboxylate group being planar with the phenyl ring. A complete set of frequencies (except for the torsional mode) was given by Green:⁵⁹ 3073–3036 (triplet),

1595, 1488, 1413, 1172, 1150, 1026, 1006, 974, 845, 840, 680, 400, 397 (all of A-type), and 3088 (twice), 1595, 1552, 1413, 1305, 1301, 1157, 1065, 985, 919, 819, 709, 683, 617, 526, 418, 238, and 170 (all of B-type) cm^{-1} from the infrared spectrum in KCl disks and Nujol mulls, and confirmed by the Raman spectrum where possible. This set was more or less confirmed by other authors,⁶⁰⁻⁶² with deviations that are of no consequence for the thermodynamic functions. The torsional frequency was taken as 139 cm^{-1} from the data for nitrobenzene,⁶³ since the nitrobenzene molecule is similar to the isoelectronic and isostructural benzoate anion. This assignment is confirmed by its presence in the Raman, but not in the infrared, spectrum of nitrobenzene.⁶⁴ The resulting thermodynamic functions are shown in Table 22.

(23) *Guanidinium, $\text{C}(\text{NH}_2)_3^+$* : This planar trigonal ion has symmetry D_{3h} , all the angles are 120°, and the bond distances are $r(\text{C-N})=0.133$ and $r(\text{N-H})=0.100 \text{ nm}$.⁶⁵ The published sets of vibrational frequencies are incomplete, since three A-type vibrations are inactive in both the Raman and infrared spectra. The reported frequencies⁶⁶ derived from both kinds of spectra in aqueous solution (Raman) and crystalline chloride salt (infrared) are: 3340, 1625, 1015, 725, and 520 (all A-type), 3400, 3320, 1670, 1565, 1140, 536, 830, and 500 (all E-type) cm^{-1} , in good agreement with other reports.⁶⁷⁻⁶⁹ The missing frequencies are assignable to C-N-H bending, NH₂ rocking, and N-H stretching, with estimated frequencies of 500, 1100, and 3300 cm^{-1} , respectively, in analogy with the reported active frequencies for these internal coordinates. A variation of up to 20% in the estimated frequencies causes changes in the entropy and Gibbs function that do not exceed 1–2 $\text{J K}^{-1} \text{mol}^{-1}$. The resulting thermodynamic functions are shown in Table 23.

(24) *Glycine zwitterion, ${}^+ \text{H}_3\text{NCH}_2\text{CO}_2^-$* : This form of gly-

cine, in the crystalline state and present in aqueous solutions at a pH range that envelops the isoelectric point, pH=6.0, is considered to have C_s symmetry in the isolated form. According to theoretical calculations,⁷¹ the barriers to free internal rotation of the -NH₃ and the -CO₂ groups are high: 878 or 2341 cm^{-1} (two alternative energies: 10.5 or 28.0 $\text{J K}^{-1} \text{mol}^{-1}$ having been suggested according to two basis sets) for the former and 4197 cm^{-1} (50.2 $\text{J K}^{-1} \text{mol}^{-1}$) for the latter. The bond distances are $r(\text{C-N})=0.147$, $r(\text{C-C})$

$=0.152$, $r(C-O)=0.127$, $r(C-H)=0.109$, and $r(N-H)=0.103$ nm, the angles are $\angle OCO=122^\circ$, $\angle C(N)CO=119^\circ$, and the rest are tetrahedral, 109.47° .⁷⁰ A complete set of vibration frequencies (except for the five N-H and C-H stretching frequencies), both observed in and calculated for the Raman and infrared spectra of solid glycine, was reported by Machida *et al.*⁷¹ The following data are the observed (calculated) values for the Raman spectrum in aqueous solution: 1669, 1642, 1570, 1513, 1441, 1410, 1324, (1328), 1139, (1108), 1034, (920), 890, 695, 603, 495, (472), 356, and 194 cm $^{-1}$. The -NH $_3$ torsion frequency is 472, the -CO $_2$ torsion frequency is 194 cm $^{-1}$. The not-reported stretching frequencies are all >3000 cm $^{-1}$, hence of no consequence for the thermodynamic functions. This set,⁷¹ used for our calculations, is in good agreement with other results.⁷²⁻⁷⁵ The several low frequencies reported for the crystalline state are probably lattice modes.⁷² The 110 cm $^{-1}$ frequency observed in the solid was assigned to the -CO $_2$ torsion, instead of the unassigned, 194 frequency,⁷² which we preferred (and used) because it was more consistent with the other assignments.⁷² Raman spectra of the aqueous solutions^{74,75} are in good agreement with data for the solid. A value for the -NH $_3$ torsion obtained from inelastic neutron scattering,⁷³ 527 cm $^{-1}$, is somewhat higher than calculated⁷¹ for the Raman (472 cm $^{-1}$) and infrared (486 cm $^{-1}$) spectra, but has little effect on the thermodynamic functions. The thermodynamic functions calculated from the data presented above are shown in Table 24.

Deprotonation of glycine in solutions more basic than the isoelectric point produces the *glycinate anion*, H $_2NCH_2CO_2^-$. Its structure should not differ much from that of glycine, the effects on the thermodynamic functions

would therefore be small. The slightly lower ionic mass diminishes the translational entropy by $1.5 R \ln(75/74)$, i.e., by 0.17 J K $^{-1}$ mol $^{-1}$. The absence of the light hydrogen atom rotating at ~ 0.2 nm from the center of gravity of the molecule/ion lowers the rotational entropy by 0.52 J K $^{-1}$ mol $^{-1}$. The set of vibration frequencies presented for this ion in aqueous solution is: 1603, 1454, 1430, 1405, 1346, 1316, 1168, 1110, 1082, 970, 905, 678, 587, and 516 cm $^{-1}$ is quite similar to that for glycine. This set is not only short of the required complement by the 2 C-H and 2 N-H stretching frequencies (>3200 cm $^{-1}$) which are of no consequence for the calculated thermodynamic functions, but also by 3 of the lower frequencies, which have to be estimated. Two of these should be the torsions of the -NH $_2$ and -CO $_2$ groups, which we take here to be the same as for glycine. The 359 cm $^{-1}$ frequency (assigned in glycine to CCN bending and CO $_2$ rocking)⁷⁵ should not be affected by the absence of one hydrogen on the nitrogen atom. The thermodynamic functions for the glycinate anion calculated with this tentative set are shown in Table 25.

Similar arguments pertain to the protonated glycine in solutions more acidic than the isoelectric point, producing the *glycinium* ion, $^+H_3NCH_2COOH$. The increase in the mass raises the translational entropy by 0.17 J K $^{-1}$ mol $^{-1}$. Again, on the assumption that the structure does not change appreciably except for addition⁷⁰ of $r(O-H)=0.097$ nm and $\angle COH=120^\circ$, the rotation of the extra hydrogen atom at ~ 0.3 nm from the center of gravity is expected to add 0.36 J K $^{-1}$ mol $^{-1}$ to the rotational entropy. The set of vibrational frequencies reported⁷⁵ for aqueous solutions is: 1745, 1628, 1513, 1440, 1418, 1327, 1268, 1135, 1048, 903, 878, 655, 573, 509, 313 cm $^{-1}$, and is again short of the expected number, even with the stretching frequencies (3 N-H, 2 C-H, and

1 O-H) excluded. The missing frequencies have to be estimated: for the torsions of -NH₃ and -CO₂H are taken the glycine values, and twice ~ 1500 and twice ~ 1000 are added. The resulting calculated thermodynamic functions are shown in Table 26.

3. Discussion

The results presented in this work are an extension of our efforts^{1,2} to provide thermodynamic functions for a variety of ionic species based upon critically reviewed structural and spectroscopic data. Such quantities, beyond being of interest in their own right, provide essential data for the evaluation of changes in thermodynamic quantities in the solvation processes in which such ions may be involved. This *rationale* guided us in the choice of ions discussed and also in the preference of solution data over those obtained from solid phase spectroscopic or structural analyses. It might be argued that the presented data are for a reference state of *isolated single ions* rather than for the ionic species as they actually exist in the gas phase at the relevant temperatures.

The latter remark pertains mostly to the disregard of free internal rotation in our considerations, even at the higher end of the temperature range. In the great majority of cases such attitude is also justified by physical considerations: the classical text by Brewer and Pitzer⁷⁶ states that free internal rotation is said to be of significance when the potential barrier is considerably lower than 695 cm^{-1} , the value of $k \cdot T$ at 1000 K.

In several cases a symmetrical structure was chosen even if the possibility of slight deviations from it was indicated by the relevant literature pertaining to diffraction results in solid compounds. We checked the sensitivity of our results to the

effect of such deviations and adopted this attitude when we found the geometrical effects to be rather small (less than 1%). However, a reduction of symmetry may well involve a reduction in the symmetry number and appropriate change in the rotational contribution to the calculated thermodynamic functions. Again we feel that the higher symmetry may be more appropriate for the consideration of isolated ions or ions in solution. Moreover, the question what size of deviation (and at what temperature and barrier) justifies a postulation of a lowered symmetry is more of a philosophical nature and beyond the scope of this contribution.

In considering the structural and spectroscopic data we often had to decide between several (and sometimes conflicting) sets, especially where vibrational frequency values and assignments are concerned. Having made our choice of the most reasonable set of values, the ones from which the functions are tabulated, we also indicate the uncertainty involved, if other sets of similar reliability were to be chosen. When an alternative set greatly deviates from the one chosen for the calculations in the tables, we quote the relevant data and estimate the variation they would impose in the calculated value, but also indicate in the accompanying text that we regard these data to be of lower validity. In ascertaining the effects of variations in frequencies and assignments on the presented entropy values, our previously published table on the dependence of the calculated vibrational contributions on the frequency values and temperature should be useful.²
