

# Accurate Atomic Transition Probabilities for Hydrogen, Helium, and Lithium

W. L. Wiese and J. R. Fuhr<sup>a)</sup>

National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA

(Received 13 January 2009; accepted 13 January 2009; published online 24 June 2009; publisher error corrected 23 September 2009)

We have carried out a comprehensive tabulation of the atomic transition probabilities for allowed and forbidden lines of hydrogen, helium and lithium, including Li II, as well as the hydrogen isotopes deuterium and tritium. Altogether, we tabulated about 3600 transitions and listed scaling relations for the hydrogenlike ions He II and Li III. The selected data are based on a critical evaluation of available literature sources and are all taken from recent advanced calculations. The tables are normally arranged in multiplets, and these are ordered in increasing excitation energies. For hydrogen, deuterium, and tritium, the energy levels are degenerate, i.e., all energy levels of the same principal quantum number essentially coincide. Thus, the principal tables for these species are for the average transition probabilities of lines between different principal quantum numbers. © 2009 by the U. S. ## 1. Introduction

### 1.1. Overview

In 1966, the first reference data tables for the atomic transition probabilities of the light elements hydrogen to neon, atomic numbers 1–10, were published by the National Bureau of Standards (NBS),<sup>1</sup> now the National Institute of Standards and Technology (NIST). Since then, large amounts of much higher quality data have become available, most from quantum mechanical calculations. These advanced calculations became feasible due to a combination of sophisticated new atomic structure codes and the greatly increased power of computers. Since this new material covers the spectra more extensively, our present NIST reference data tables are greatly expanded and are therefore being published in several parts. The first part, containing all spectra of carbon, nitrogen and oxygen, was already published in 1996,<sup>2</sup> and an addendum for C I and C II and N I and N II, again with much improved data sets, has also been completed.<sup>3</sup>

Most of the tabulated data for this second major part are the results of two extensive very high precision calculations: For hydrogen and its isotopes, we have tabulated new calculations by Baker, whose results are recorded in Ref. 4, and by Jitrik and Bunge.<sup>5</sup> The two sets of data were obtained from fully relativistic calculations and yielded identical results for the transition probabilities, where they overlap. For neutral helium and singly ionized lithium, we have tabulated the results of variational calculations by Drake,<sup>6-8</sup> which for most practical purposes may be considered as essentially exact. Drake applied his sophisticated computational techniques to more than 2400 transitions of He I and about 500 transitions of heliumlike Li II.

In contrast to these high-precision calculations—and some similar smaller, slightly less refined theoretical works—experimental results have played only a minor role for this compilation, essentially serving to reaffirm the calculations.

### 1.2. Brief Remarks on the Principal Data Sources

Hydrogen and the hydrogenlike ions He II and Li III are special cases because (a) they are one-electron atomic systems for which the transition probabilities have been calculated on a practically exact basis, except for very small quantum electrodynamic (QED) corrections, and (b) all energy levels for a given principal quantum number  $n$  essentially coincide (which is known as the  $lj$  degeneracy). We have tabulated the new fully relativistic data by Baker<sup>4</sup> and by Jitrik and Bunge.<sup>5</sup> Baker, with his results appearing in Ref. 4, also provided explicit results for the "average" transition probabilities of transitions  $n_i-n_k$  which are of the utmost practical importance and give rise to the familiar Lyman, Balmer, Paschen, etc., lines. We have found that for the great majority of transitions, Baker's results, which include a finite mass term, are for the first four digits identical to the non-relativistic calculations by Green *et al.*,<sup>9</sup> which we used in our 1966 NBS reference tables. The only exceptions, i.e., extremely slight differences with a change in the last digit by one or two, occur in such highly excited transitions as from principal quantum numbers 19 and 20. For these, minute changes in the transition energy may be partly responsible. Baker<sup>4</sup> also calculated relativistic transition probabilities for the hydrogen isotopes deuterium and tritium, again with the finite mass term, and found—not surprisingly—only very small changes in the transition energies and probabilities. Therefore, our tables for these isotopes are kept small, covering principal quantum numbers of 20 and below.

Very high precision variational and asymptotic expansion methods for neutral helium and some heliumlike ions were developed in the 1980s and 1990s by Drake,<sup>6-8</sup> refining an earlier, already quite sophisticated, variational approach by Schiff and Pekeris<sup>10</sup> in the 1960s. Drake's work provides essentially exact calculations of the nonrelativistic energies including the lowest-order relativistic corrections for the entire spectrum of helium and singly ionized lithium. His calculated energies were compared with extremely accurate experimental energies in order to find the magnitude of the residual differences due to higher-order relativistic and QED corrections. These turned out to be so small that they are estimated to produce only occasional small changes in the fourth or fifth digit of the numerical transition probability data we provide in this tabulation. Drake stated that replacing his calculated transition energies by the experimental ones will not necessarily produce higher accuracy for the transition probabilities because there are also relativistic corrections in the transition operator itself that must be included.

Based on his results for the helium energy levels, Drake proceeded to calculate transition probabilities that include

the singlet-triplet mixing terms as the lowest-order but largest relativistic contribution. These represent a well-defined theoretical result accurate to at least 0.3% or better. His results for the dipole length and velocity formulations agree normally for the first eight to ten digits (he carried his calculations out to 14+ figures). He also chose the infinite nuclear mass case for the main reason that—at least for the transition frequencies—relativistic and nuclear mass polarization corrections are comparable in magnitude but of opposite sign. Drake and Morton<sup>11</sup> recently undertook an extensive comparison of these calculated energies with experimental high-precision energies as well as with some precise lifetime data and confirmed the outstanding accuracy of the calculated data.

For the spectrum of Li I, the data situation is quite different. In order to produce extensive coverage, we had to apply the results of seven different advanced calculations which were carried out over the past 20 years. For this atom of still simple structure, the agreement between different authors, where their results overlap, is remarkably good, normally within 0.5% for the stronger transitions. However, for the very weak lines, disagreements become significant, and for the weakest line tabulated here, it reaches a factor of 2 mainly due to severe cancellation in the transition integral. Fortunately, these few transitions are the only exceptions to a table of otherwise truly accurate atomic transition probabilities.

### 1.3. Scaling Relationships for Hydrogenlike He II and Li III

Transition probabilities  $A_{ki}$ , oscillator strengths  $f_{ik}$ , and line strengths  $S$  for the hydrogenlike ions He II and Li III may be obtained from the data for the corresponding hydrogen lines by using the following scaling relationships:<sup>12</sup>

$$A_{ki}(Z) = Z^4 A_{ki}(H) \frac{\mu(Z)}{\mu(H)},$$

$$f(Z) = f(H) \frac{\mu(H)}{\mu(Z)},$$

and

$$S(Z) = Z^{-2} S(H) \left( \frac{\mu(H)}{\mu(Z)} \right)^2,$$

where the quantities for hydrogen are indicated by  $H$  and those for the hydrogenlike ions by their nuclear charges  $Z$ . These relationships include a term for the finite masses of  $H$  and the  $H$ -like ions, expressed by their reduced masses  $\mu(Z) = M(Z) / [m_e + M(Z)]$  ( $m_e$  is the electron mass and  $M(Z)$  is the mass of the nuclide of charge  $Z$ ). They are valid for hydrogenlike ions of small  $Z$  because relativistic effects are negligibly small. For wavelength and energy level data, the NIST Atomic Energy Levels and Spectra Bibliographic Database<sup>13</sup> and the NIST Atomic Spectra Database<sup>14</sup> (ASD) should be consulted. (In the nonrelativistic approximation, the wavelengths  $\lambda$  scale as  $\lambda(Z) = Z^{-2} \lambda(H) [\mu(H) / \mu(Z)]$ .)

### 1.4. List of Symbols

Symbols for indication of data accuracy:

- AAA = uncertainty less than  $\pm 0.3\%$
- AA = uncertainty less than  $\pm 1\%$
- A = uncertainty less than  $\pm 3\%$
- B = uncertainty less than  $\pm 10\%$
- C = uncertainty less than  $\pm 25\%$
- D = uncertainty less than  $\pm 50\%$
- E = uncertainty greater than  $\pm 50\%$ , but within a factor of 3

Symbols used for the table headings:

- $\lambda$  = Wavelength ( $\text{\AA}$ )
- $E_i$  = lower energy level ( $\text{cm}^{-1}$ )
- $E_k$  = upper energy level ( $\text{cm}^{-1}$ )
- $g_i$  = statistical weight of lower level
- $g_k$  = statistical weight of upper level
- $A_{ki}$  = atomic transition probability for spontaneous emission ( $10^8 \text{ s}^{-1}$ ) for all E1 (allowed: electric dipole) transitions,  $\text{s}^{-1}$  for all M1, M2, and E2 transitions
- $f_{ik}$  = absorption oscillator strength
- $S$  = line strength in a.u.; formulas and values for these quantities in SI units are as follows:

For E1 transitions:

$$a_0^2 e^2 = 7.188_3 \times 10^{-59} \text{ m}^2 \text{ C}^2$$

For E2 transitions:

$$a_0^4 e^2 = 2.012_9 \times 10^{-79} \text{ m}^4 \text{ C}^2$$

For M1 transitions:

$$\mu_B^2 = (eh / \pi m e)^2 = 8.600_7 \times 10^{-47} \text{ J}^2 \text{ T}^{-2}$$

For M2 transitions:

$$\mu_B^2 a_0^2 = 2.408_5 \times 10^{-67} \text{ J}^2 \text{ m}^2 \text{ T}^{-2}$$

where  $a_0$ ,  $e$ ,  $m_e$ , and  $h$  are the Bohr radius, electron charge, electron mass, and Planck constant, respectively, and  $\mu_B$  is the Bohr magneton. Note that for  $E_i$  and  $E_k$ , the customary unit for atomic energy levels, used here, is related to the SI unit for energy (J) by  $1 \text{ cm}^{-1} = 1.986 \times 10^{-23} \text{ J}$ .

Abbreviations appearing in the column labeled “type” (forbidden lines only):

- M1: magnetic dipole transition
- E2: electric quadrupole transition
- M2: magnetic quadrupole transition

Special symbols used in the wavelength and energy level columns: Numbers in italics indicate multiplet values, i.e., weighted averages of line values. Notation for exponents: In all tables, we have shown the power of 10 by the exponential notation. For example,  $3.88\text{e}-03$  stands for  $3.88 \times 10^{-3}$ .

### 1.5. Useful Relations

We present only relations pertinent to H, He, and Li. For more extensive descriptions of spectroscopic terminology, selection rules, relations between multiplets and fine structure lines, etc., see Refs. 15 and 16.

(A) Statistical weight  $g$ :

- (1) The statistical weight of a level is related to the total angular momentum or quantum number  $J_L$  ( $j$  for one-electron spectra) of that level (initial or final state of a line) by

$$g_L = 2J_L + 1.$$

- (2) Similarly, the statistical weight of a term (initial or final state of a multiplet) is

$$g_M = (2L + 1)(2S + 1),$$

where  $L$  is the total orbital angular momentum and  $S$  is the total spin angular momentum. For the one-electron spectra of hydrogen and hydrogenlike ions, lowercase letters  $l$ ,  $s$ , and  $j$  are used, and a particular level is denoted either by  $nl_j$  or by  $nl^2L_J$ , with  $L=l$  and  $J=j$ .

(B) Relations between the strengths of (LS-allowed) fine structure lines and the total multiplet strength:

- (1) Line strength  $S$ : The line strength of a multiplet is the sum of the strengths of its component lines, i.e.,

$$S(\text{multiplet}) = \sum S(\text{line})$$

or

$$S(i, k) = \sum_{J_i, J_k} S(J_i, J_k),$$

where  $k$  denotes the upper term and  $i$  denotes the lower term.

- (2) Absorption oscillator strength  $f_{ik}$ :

$$f_{ik}^{\text{multiplet}} = \frac{1}{\langle \lambda \rangle_{ik} \sum_{J_i} (2J_i + 1)} \sum_{J_i, J_k} (2J_i + 1) \times \lambda(J_i, J_k) \times f(J_i, J_k).$$

The mean wavelength for the multiplet,  $\langle \lambda \rangle_{ik}$ , may be obtained from the *weighted* energy levels. Often the wavelength differences for the lines within a multiplet are small, in which case the wavelength factors may be neglected.

- (3) Transition probability  $A_{ki}$ :

$$A_{ki}^{\text{multiplet}} = \frac{1}{\langle \lambda \rangle_{ik}^3 \sum_{J_k} (2J_k + 1)} \sum_{J_i, J_k} (2J_k + 1) \times \lambda(J_i, J_k)^3 \times A(J_i, J_k).$$

(C) Definition of the average transition probabilities for hydrogen and hydrogenlike ions (due to the  $l$  degeneracy) in terms of  $n_i l_i - n_k l_k$  multiplet values:

1

$$A_{n_k n_i}^{\text{avg}} = \sum_{l_k, l_i} \frac{2l_k + 1}{n_k^2} A_{(nl)_k, (nl)_i},$$

2

$$f_{n_i n_k}^{\text{avg}} = \sum_{l_k, l_i} \frac{2l_i + 1}{n_i^2} f_{(nl)_i, (nl)_k},$$

3

$$S_{n_i n_k}^{\text{avg}} = \sum_{l_k, l_i} S_{(nl)_i, (nl)_k}.$$

The multiplet values are in turn related to the values for the fine structure lines as shown in (B) above.

(D) Conversions:

- (1) For electric dipole (E1-allowed) transitions,

$$A_{ki} = \frac{6.670\,251\,7 \times 10^{15} g_i f_{ik}}{g_k \lambda^2} = \frac{2.026\,126\,9 \times 10^{18}}{g_k \lambda^3} S.$$

- (2) For magnetic dipole (M1-forbidden) transitions,

$$A_{ki} = \frac{2.697\,350\,0 \times 10^{13}}{g_k \lambda^3} S.$$

- (3) For electric quadrupole (E2-forbidden) transitions,

$$A_{ki} = \frac{1.119\,950\,0 \times 10^{18}}{g_k \lambda^5} S.$$

- (4) For magnetic quadrupole (M2-forbidden) transitions,

$$A_{ki} = \frac{1.490\,971\,4 \times 10^{13}}{g_k \lambda^5} S.$$

For these conversions,  $\lambda$  is the vacuum wavelength in Å units, and  $g_i$  and  $g_k$  are the statistical weights of the lower and upper levels, respectively. The line strength ( $S$ ) is given in a.u., the transition probability ( $A_{ki}$ ) is in units of  $\text{s}^{-1}$ , and the  $f$  value is dimensionless. For more details on these units and conversion factors, we refer the reader to Wiese *et al.*<sup>2</sup>

## 2. Hydrogen (H I) and its Isotopes D I and T I

### 2.1. H I

Ground State:  $1s^2S_{1/2}$

Ionization Energy (H I): 13.598 eV (109 678.7737  $\text{cm}^{-1}$ )

#### 2.1.1. H I, D I, and T I Allowed Transitions

Hydrogen and hydrogenlike ions represent special cases with respect to their spectra. They are two-body atomic systems, for which the wavelengths, energy levels, and transition probabilities can be calculated on an essentially exact basis. Such calculations were first done nonrelativistically and provided transition probabilities accurate to four significant figures for hydrogen as well as for light hydrogenic ions.<sup>9</sup> Recently, more sophisticated calculations were carried out on a fully relativistic basis and including a finite mass term by Baker,<sup>4</sup> Jitrik and Bunge,<sup>5</sup> and Pal'chikov.<sup>17</sup> For the energy levels, even more refined calculations including QED effects,<sup>5</sup> were recently undertaken, so that the latter quantities are now known to at least 13 significant figures.

The hydrogen spectrum possesses another unique feature insofar as all energy levels for a given principal quantum number  $n$  are degenerate, that is, they essentially coincide. Thus, in laboratory or astrophysical plasmas, where the excited atoms undergo many transitions during their lifetimes and where pressure (Stark) and Doppler broadening are present, only one spectral line is observed for all possible transitions from an upper level  $n_k$  to a lower level  $n_i$ . Therefore, the average (sometimes called the total) transition probabilities for transitions  $n_i-n_k$  assume great importance, giving rise to the well-known Lyman, Balmer, Paschen, etc., lines, and they are the data in our principal table.

Baker explicitly calculated these very important average transition probabilities from upper levels  $n_k$  to lower levels  $n_i$  for all combinations of  $n_i \leq 19$  and  $n_k \leq 20$  (where  $n$  is the principal quantum number). For the important Lyman, Balmer, and Paschen spectral series, he extended his calculations to  $n_i \leq 39$  and  $n_k \leq 40$ . Therefore, we have used his results. Actually, forbidden transitions (M1, E2, M2, E3, etc.) must be also included in the averaged transition probabilities, but they are totally negligible (see the comment below on Jitrik and Bunge's calculations).

The average transition probabilities  $A_{ki}$ , oscillator strengths  $f_{ik}$ , and line strengths  $S$  are obtained from the values for multiplets  $n_i l_i - n_k l_k$  and for fine structure lines  $n_i l_i j_i - n_k l_k j_k$  by the relations shown in Sec. 5 of the general introduction to this compilation.

For the fine structure lines  $n_i l_i j_i - n_k l_k j_k$  (where  $l$  is the orbital angular momentum quantum number and  $j$  is the total angular momentum quantum number), we have utilized the fully relativistic calculations by Baker<sup>4</sup> and Jitrik and Bunge<sup>5</sup> for all transitions between lower levels with  $n_i \leq 5$  and upper levels with  $n_k \leq 6$  for all possible values of  $l_i j_i$  and  $l_k j_k$ . The data of Baker<sup>4</sup> and Jitrik and Bunge<sup>5</sup> turned out to be identical for the transition probabilities but differ slightly for the

$f$  and  $S$  data, where Jitrik and Bunge apparently did not correct for the finite mass. Pal'chikov<sup>17</sup> used the same computational approach but provided only few numerical transition probability data but in complete agreement with Refs. 4 and 5.

Finding lists and transition probabilities of the allowed lines of H I (both average and fine-structure) are given in Tables 1–6, while finding lists and transition probabilities for the allowed lines of the hydrogen isotopes D I and T I are given in Tables 7–10.

Baker<sup>4</sup> and Jitrik and Bunge<sup>5</sup> also calculated energy levels and wavelengths but did not include QED effects in their calculations. However, these are estimated to be very small and will only start to affect the sixth and higher digits in the tabulated numbers. (For the  $2s$  and  $2p$  levels, a numerical change of 1 already occurs in the fifth digit.) Jitrik and Bunge also calculated the strengths of forbidden lines, i.e., M1, M2, M3, E2, and E3 transitions, which all occur at the same wavelengths as the allowed electric dipole (E1) lines because of the above-noted energy level degeneracy for hydrogen. The forbidden lines were found to be smaller than the E1 lines by many orders of magnitude, so that their contributions to the averaged line strengths are totally negligible.

It should be noted that the comprehensive nonrelativistic calculations by Green *et al.*,<sup>9</sup> which were utilized in the first NBS/NIST compilation for hydrogen in 1966,<sup>1</sup> delivered almost identical results as the recent relativistic calculations,<sup>4,5,17</sup> that we have employed here. We show comparisons of relativistic and nonrelativistic results for a few selected transitions in Table 2.

For the energy levels and wavelengths, we used the results of several recent sources. For the  $n l j$  levels and fine structure lines, we took the data from Jentschura *et al.*,<sup>18</sup> in which all significant relativistic and QED corrections are included. Their results are given in the NIST Physical Reference Data website to 14 significant digits. These values agree almost perfectly with results compiled and analyzed by Reader,<sup>19</sup> which are based on data calculated by Erickson,<sup>20</sup> who also included relativistic and QED effects. Reader also computed the averaged energy levels and wavelengths for the six strongest Lyman and five strongest Balmer lines, which we have tabulated. For the higher Lyman and Balmer lines, as well as for lines of the Paschen, Brackett, and higher spectral series, we used the calculated averages by Baker.<sup>4</sup> For the strong Lyman and Balmer lines, these values agree closely with the data of Reader, with differences of only 1, 2, or 3 showing up in the sixth digit.

We also present short tables of average values for the hydrogen isotopes, deuterium and tritium, because of their importance in magnetic fusion research. For the isotopes, only the mass of the nucleus changes, so that the  $A$  values are readily modified by the ratios of the reduced mass for D or T against H.<sup>4</sup> The changes compared to hydrogen itself are very small, amounting consistently to a slight increase in the fourth digit. Numerical comparisons for the first two Lyman and Balmer lines are shown in Table 3.

TABLE 1. List of tabulated lines for allowed transitions of H I, average values

| Wavelength (Å) | Multiplet No. |
|----------------|---------------|
| In vacuum      |               |
| 912.321        | 39            |
| 912.351        | 38            |

<sup>a</sup>Wavelengths ( $\text{\AA}$ ) are always given unless  $\text{cm}^{-1}$  is indicated.

### 2.1.2. H I, D I, and T I Forbidden Transitions

Of the forbidden lines of hydrogen, the magnetic dipole transition arising from the hyperfine splitting of the ground level  $1s^2S_{1/2}$  into two sublevels has acquired great importance in radio astronomy. This transition, arising from the interaction of the magnetic moments of the proton and its

electron, produces the famous 21 cm line, i.e., a radio frequency line at 1420.405 751 8 MHz, which has been observed in interstellar space.

Gould<sup>21</sup> carried out a detailed, improved calculation of the transition probability for the 21 cm line, including the effect of the first-order radiative correction to the intrinsic magnetic

moment of the electron and the effect of the coupling of the outgoing photon to the magnetic moment of the nucleon/nucleus. These effects produce very small changes to the zeroth-order formula, where the line strengths are either 3 or 16/3, respectively. Gould estimated that his results are accurate to 1 ppm. We include his results for the analogous hyperfine transitions of deuterium and tritium, which occur at significantly different frequencies.

Other forbidden transitions have no practical significance. Due to the hydrogen energy-level degeneracy, their transition frequencies essentially coincide with the allowed lines of the same principal quantum numbers, but the latter ones are orders of magnitude stronger and thus overwhelm the forbidden line contributions.

Jitrik and Bunge<sup>5,22</sup> recently calculated the forbidden line

strengths for electric and magnetic multipole transitions up to E3 and M3 (octupole transitions). In a special table, we have assembled the transition probabilities of these forbidden lines for the two transitions from the  $n=1$  to  $n=2$  and 3, i.e., essentially components of the  $L_\alpha$  and  $L_\beta$  transitions. We also show the strengths of the allowed transitions for  $L_\alpha$  and  $L_\beta$  and the averaged transition probabilities for these two lines in order to provide a quantitative comparison for the strengths of all these components. For the  $n=1$  to  $n=3$  transition ( $L_\beta$ ) the addition of the forbidden components increases the transition probability only by one unit in the fifth digit (due to E2).

Transition probabilities for the forbidden lines of (H I), (D I), and (T I) are given in Tables 11 and 12.

### 3. Helium

#### 3.1. He I

Ground State:  $1s^2 \ ^1S_0$

Ionization Energy: 24.587 eV (198 310.6672 cm<sup>-1</sup>)

##### 3.1.1. He I Allowed Transitions

The high-precision variational calculations by Drake,<sup>6</sup> recently published in full by Drake and Morton,<sup>11</sup> provided the

definitive set of data for neutral helium and may be considered as essentially exact for most applications. Drake's calculations produced transition probability data for about 2400 transitions with principal quantum numbers up to 10 and orbital angular momentum quantum numbers up to 7 with an estimated accuracy of about 0.1%. Drake calculated the transition integrals both in the dipole length and dipole velocity formulations and achieved agreement of the two forms to at least several more significant figures than given in our tabu-

lation. He included the lowest-order relativistic terms in his calculations, thus taking into account singlet-triplet mixing. Drake stated that higher-order relativistic and QED effects are only expected to change the fourth and higher digits in the numerical results.

Drake and Morton<sup>11</sup> converted the tabulated transition probabilities into oscillator strengths by utilizing their calculated nonrelativistic wavelengths for the various transitions. We used higher-precision experimental wavelengths (listed in the NIST ASD) for this conversion, making our oscillator strengths slightly different.

Drake<sup>8</sup> also calculated precise radiation data for several intercombination lines, among them the principal intercombination transition  $1s^2\ ^1S_0-1s2p\ ^3P_1$ . Since the helium spectrum is very close to LS coupling, the intercombination or "non-LS-allowed" lines are quite weak.

A finding list and transition probabilities for the allowed lines of (He I) are given in Tables 13 and 14.

<sup>a</sup>Wavelengths ( $\text{\AA}$ ) are always given unless  $\text{cm}^{-1}$  is indicated.

### 3.1.2. He I Forbidden Transitions

For the electric quadrupole lines, we have tabulated the results of recent extensive variational calculations by Cann and Thakkar.<sup>23</sup> They constructed 100-term explicitly correlated wave functions and derived the quadrupole oscillator strengths in both the length and velocity formulations. The two formulations almost always gave excellent agreement, usually within 0.1% and slightly exceeding 1% only for the  $1s3s\ 1\text{S}-1s6d\ 1\text{D}$  transition.

Cann and Thakkar already applied the same computational approach to the allowed lines of He I and in this case obtained almost perfect agreement with the calculations by Drake,<sup>6</sup> which are tabulated for the allowed (E1) lines.

For the three transitions  $1s^2\ 1\text{S}-1s3d\ 1\text{D}$ ,  $1s2s\ 1\text{S}-1s3d\ 1\text{D}$ , and  $1s2s\ 3\text{S}-1s3d\ 3\text{D}$ , electric quadrupole line strengths were also calculated by Godefroid and Verhaegen<sup>24</sup> with a multiconfiguration Hartree-Fock program developed by Froese Fischer<sup>25</sup> in 1977. The agreement with the results of Cann and Thakkar<sup>23</sup> is within 0.5%.

Drake<sup>26</sup> and Johnson and Lin<sup>27</sup> calculated the transition probability of the  $1s^2\ 1\text{S}-1s2s\ 3\text{S}$  relativistic magnetic dipole transition using perturbation theory and the Dirac-Fock approximation, respectively, and their results agree within

1.5%. This very weak transition has also been measured by Woodworth and Moos<sup>28</sup> in a He discharge, their results agreeing with the calculations within 15%.

Drake<sup>29</sup> and Kundu *et al.*<sup>30</sup> calculated the magnetic quadrupole transition rates for several  $1s^2\ 1\text{S}-1snp\ 3\text{P}^\circ$  transitions with variational and Hartree-Fock methods, respectively. Their calculations overlap for the  $1s^2\ 1\text{S}-1s2p\ 3\text{P}^\circ$  transition, where their results differ by only 11%.

A finding list and transition probabilities for the forbidden lines of (He I) are given in Tables 15 and 16

TABLE 15. List of tabulated lines for forbidden transitions of He I

| Wavelength ( $\text{\AA}$ ) | No. |

<sup>a</sup>Wavelengths ( $\text{\AA}$ ) are always given unless  $\text{cm}^{-1}$  is indicated.

### 3.2. He II

Hydrogen Isoelectronic Sequence

Ground State:  $1s^2S_{1/2}$

Ionization Energy: 54.418 eV (438 908.886  $\text{cm}^{-1}$ )

#### 3.2.1. He II Allowed Transitions

We have not tabulated numerical data for the hydrogenlike ion He II. Data for this ion of nuclear charge  $Z=2$  may be obtained by scaling the tabulated values for hydrogen according to the following nonrelativistic relationships:<sup>12</sup>

$$f(\text{He II}) = f(\text{H I}),$$

$$A(\text{He II}) = (2)^4 A(\text{H I}) = 16A(\text{H I}),$$

$$S(\text{He II}) = (2)^{-2} S(\text{H I}) = (1/4)S(\text{H I}).$$

Extensive numerical calculations for H-like ions by Baker,<sup>4</sup> Jitrik and Bunge,<sup>5</sup> and Pal'chikov<sup>17</sup> showed that the relativistic results are essentially indistinguishable (i.e., identical within a few parts in  $10^4$ ) from the nonrelativistic results for hydrogen and hydrogenlike ions of small  $Z$ . Therefore the above scaling relationships are valid within this level of accuracy. If better precision is required, we refer the reader to the data tables by Jitrik and Bunge.<sup>5</sup>

Wavelength and energy level data for He II may be obtained by consulting the NIST Atomic Energy Levels and Spectra Bibliographic Database.<sup>13</sup>

#### 3.2.2. He II Forbidden Transitions

The magnetic dipole transition between the two hyperfine levels of the ground state of  $^3\text{He II}$ , which is an analog to the famous 21 cm line of hydrogen, has been investigated in detail by Gould,<sup>21</sup> who obtained a transition probability of  $A=1.954\,36 \times 10^{-12} \text{ s}^{-1}$  for it (he used a transition frequency of 8665.649 905 MHz, which was obtained from literature sources).

## 4. Lithium

### 4.1. Li I

Ground State:  $1s^2 2s^2 S_{1/2}$

Ionization Energy: 5.3917 eV (43 487.150  $\text{cm}^{-1}$ )

#### 4.1.1. Li I Allowed Transitions

Numerous results for the transition probabilities of this spectrum have been obtained in recent years, almost all from calculations. We selected data from seven advanced calculations<sup>31-37</sup> and used high-precision radiative lifetime measurements<sup>38-40</sup> for an independent check of some theoretical results. The majority of tabulated data comes from the close-coupling calculations by Peach *et al.*<sup>37</sup>

A finding list and transition probabilities for the allowed lines of (Li I) are given in Tables 17-19.

The highest precision calculations were carried out by Yan and Drake<sup>31</sup> for the  $2s^2S-2p^2P^\circ$  and the  $2p^2P^\circ-3d^2D$  mul-

tiplets by constructing variational wave-functions in Hylleraas coordinates. They calculated the oscillator strengths for two transitions in both the dipole length and velocity formulations and obtained outstanding agreement. For the  $2s^2S-2p^2P$  transition, the two forms agree within six digits, and for the  $2p^2P-3d^2D$  transition, within five digits. These data may therefore serve as benchmarks for other calculations and lifetime experiments. We have made such a comparison in Table 18. We limited it to those advanced calculational methods that we used for our tabulation and high-precision experimental data from recent lifetime measurements obtained with the beam-gas-laser method<sup>38</sup> and with photoassociative spectroscopy of ultracold lithium.<sup>39,40</sup> The agreement of all these results with Yan and Drake's benchmark data is indeed impressive.

Results for other transitions of Li I were selected in the following order: First, the variational-Hylleraas-type calculations by Yan,<sup>32</sup> then the multiconfiguration Hartree-Fock calculations of Froese Fischer *et al.*,<sup>33</sup> third the results of the superposition of correlated configurations method by Pestka and Woznicki,<sup>34</sup> fourth a full-core-plus-correlation method by Qu *et al.*,<sup>35,36</sup> and finally the close-coupling calculations of Peach *et al.*,<sup>37</sup> by utilizing the R-matrix technique. In addition to the data overlap for the two transitions shown in Table 1, there is also overlap for about ten other transitions between the work of Froese Fischer *et al.*, Pestka and Woznicki, Peach *et al.*, and an earlier elaborate configuration interaction calculation by Sims *et al.*<sup>41</sup> (which we did not use). The differences in the results are usually very small, one-half of 1% or less. The differences with Peach *et al.* are a little larger, up to 1.7%. However, for the very weak  $2s^2S-3p^2P^\circ$  transition, the difference between Pestka and Woznicki<sup>34</sup> and Peach *et al.*<sup>37</sup> is larger than a factor of 2. We therefore estimate larger uncertainties for the data of other weak lines between higher quantum numbers that are only covered by Peach *et al.*<sup>37</sup>

TABLE 17. List of tabulated lines for allowed transitions of Li I

| Wavelength ( $\text{\AA}$ ) | No. |
|-----------------------------|-----|
| In vacuum                   |     |
| 1 807.3                     | 98  |

<sup>a</sup>Wavelengths (Å) are always given unless cm<sup>-1</sup> is indicated.

#### 4.1.2. Li I Forbidden Transitions

Garstang<sup>42</sup> developed a general formula for the magnetic dipole line strengths of hyperfine transitions within a fixed atomic energy level and applied it to the magnetic dipole transition between the two hyperfine levels of the ground terms of the <sup>6</sup>Li and <sup>7</sup>Li isotopes. The two isotopes of lithium, with relative abundances of 7.5% and 92.5%, respectively, produce two widely separated lines, for which the transition frequencies are experimentally known.<sup>43</sup> The transitions are analogous to the astrophysically important 21 cm line of hydrogen.

Caves<sup>44</sup> calculated the oscillator strengths for a large number of electric quadrupole (E2) lines with a generalized Coulomb approximation. We have tabulated the majority of his results but excluded the very weak lines and lines between higher levels, for which no experimental wavelength and en-

ergy level data are available. Sengupta<sup>45</sup> also calculated the oscillator strengths for a number of P°–P°, D–D, F°–F°, P°–F°, and S–D transitions with Hartree-Fock wave functions, and, more recently, Beck<sup>46</sup> made a detailed study of the two E2 transitions 2p <sup>2</sup>P°–3p <sup>2</sup>P° and 2s <sup>2</sup>S–3d <sup>2</sup>D. The agreement between the three authors for these and two other P°–P° transitions (2p <sup>2</sup>P°–4p <sup>2</sup>P° and 3p <sup>2</sup>P°–4p <sup>2</sup>P°) is excellent, with differences not exceeding 5%. But for the D–D transitions, Sengupta disagreed with Caves by large factors, and it appears that his results contain incorrect statistical weights. Caves presented both  $f$  values and transition probabilities, which are fully consistent, while Sengupta displayed only  $gf$  values, and these are larger by factors of about 3. We have therefore not used his results.

A finding list and transition probabilities for the forbidden lines of (Li I) are given in Tables 20–22

<sup>a</sup>Wavelengths (Å) are always given unless cm<sup>-1</sup> is indicated.

## 4.2. Li II

Helium Isoelectronic Sequence

Ground State: 1s<sup>2</sup> 1S<sub>0</sub>

Ionization Energy: 75.6402 eV (610 079.0 cm<sup>-1</sup>)

### 4.2.1. Li II Allowed Transitions

The high-precision variational calculations by Drake<sup>6</sup> provided the definitive set of data for singly ionized (heliumlike) lithium. From his calculations, which included the lowest-order relativistic terms, we have tabulated transition probability data for about 450 transitions with principal quantum numbers up to 7 and orbital angular momentum quantum numbers up to 3. Drake calculated the transition integrals both in the dipole length and dipole velocity formulations and achieved agreement in the transition integrals to at least five significant figures and often several more.

As Drake has stated, higher-order effects, such as nuclear mass corrections and relativistic and QED effects, will only noticeably change the fifth and higher figures in the results, which is of no significance to the vast majority of applications.

Cann and Thakkar<sup>47</sup> and Chen<sup>48</sup> made precise calculations similar to Drake but on a less extensive and slightly less sophisticated basis. Where they overlap, the results are identical within the first four digits. Drake also provided precise results for several weak intercombination lines.

A finding list and transition probabilities for the allowed lines of Li II are given in Tables 23 and 24.

TABLE 23. List of tabulated lines for allowed transitions of Li II

| Wavelength (Å) | No. |
|----------------|-----|
| In vacuum      |     |
| 166.390        | 6   |
| 167.270        | 5   |
| 168.738        | 4   |

<sup>a</sup>Wavelengths (Å) are always given unless cm<sup>-1</sup> is indicated.

#### 4.2.2. Li II Forbidden Transitions

For electric quadrupole lines, we have tabulated the results of recent extensive variational calculations by Cann and Thakkar.<sup>23</sup> They constructed 100-term explicitly correlated wave functions and derived the quadrupole oscillator strengths in both the length and velocity formulations. The two formulations are in excellent agreement, usually within 0.1%, and in the worst case, within 0.85%.

Cann and Thakkar already applied the same computational approach to the allowed lines of He I and in this case obtained excellent agreement with the even more sophisticated calculations by Drake,<sup>6</sup> which we tabulated for the allowed (E1) lines.

For the three transitions  $1s^2\ ^1S-1s3d\ ^1D$ ,  $1s2s\ ^1S-1s3d\ ^1D$ , and  $1s2s\ ^3S-1s3d\ ^3D$ , electric quadrupole line strengths were also calculated earlier by Godefroid and Verhaegen<sup>24</sup> with a multiconfiguration Hartree-Fock program developed by Froese Fischer<sup>25</sup> in 1977. The agreement with the results of Cann and Thakkar<sup>23</sup> is within 0.15%.

Drake<sup>26</sup> and Johnson and Lin<sup>27</sup> calculated the transition probability of the  $1s^2\ ^1S-1s2s\ ^3S$  relativistic magnetic dipole transition using perturbation theory and the Dirac-Fock approximation, respectively, and their results agree within 0.1%. The lifetime of the  $1s2s\ ^3S$  level has been measured by Saghiri *et al.*<sup>49</sup> with a storage ring and was found to be 6% longer than Drake's<sup>26</sup> calculated value.

Drake<sup>29</sup> and Kundu *et al.*<sup>30</sup> calculated the magnetic quad-

rupole transition rates for several  $1s^2\ ^1S-1snp\ ^3P^o$  transitions with variational and Hartree-Fock calculations, respectively. Their calculations overlap for the  $1s^2\ ^1S-1s2p\ ^3P^o$  transition, and their results agree within 1%.

A finding list and transition probabilities for the forbidden lines of Li II are given in Tables 25 and 26.

<sup>a</sup>Wavelengths (Å) are always given unless cm<sup>-1</sup> is indicated.

### 4.3. Li III

Hydrogen Isoelectronic Sequence

Ground State: 1s <sup>2</sup>S<sub>1/2</sub>

Ionization Energy: 122.454 eV (987 661.027 cm<sup>-1</sup>)

#### 4.3.1. Li III Allowed Transitions

We have not tabulated numerical data for the hydrogenlike ion Li III since data for this ion of nuclear charge  $Z=3$  may be obtained by scaling the tabulated values for hydrogen according to the following relationships:<sup>12</sup>

$$f(\text{Li III}) = f(\text{H I}),$$

$$A(\text{Li III}) = (3)^4 A(\text{H I}) = 81A(\text{H I}),$$

$$S(\text{Li III}) = (3)^{-2} S(\text{H I}) = (1/9)S(\text{H I}).$$

Extensive numerical calculations for H-like ions by Baker,<sup>4</sup> Jitrik and Bunge,<sup>5</sup> and Pal'chikov<sup>17</sup> showed that the relativistic results are essentially indistinguishable (i.e., identical within a few parts in  $10^4$ ) from the nonrelativistic results for hydrogen and hydrogenlike ions of small  $Z$ . Therefore the above scaling relationships are valid within this level of accuracy, which should be more than sufficient for most applications. If extremely high accuracy is required, we refer the reader to the data tables by Jitrik and Bunge.<sup>5</sup>

Wavelength and energy level data for Li III may be obtained by consulting the NIST Atomic Energy Levels and Spectra Bibliographic Database.<sup>13</sup>

## 5. Acknowledgments

This work was partially supported by the Office of Fusion Energy Sciences at the U.S. Department of Energy. We feel very fortunate that we could make use of the comprehensive sets of He I data from G. Drake and D. Morton, the Li II material from G. Drake, and the relativistic hydrogen as well as hydrogen-isotope (D and T) data from J. Baker, and we want to express here our deep gratitude to them for their invaluable help. Without their assistance, this tabulation could not have been produced. It is also a pleasure to acknowledge many valuable discussions with Charlotte Froese Fischer.
