Forensic Genetics: Research Projects and Standards Production

Peter M. Vallone, Ph.D.
Leader, Applied Genetics Group
Forensics at NIST 2020
November 5, 2020

Disclaimer

- Points of view in this document are those of the author and do not necessarily represent the official position or policies of the U.S. Department of Commerce

- Certain commercial equipment, instruments, and materials are identified in order to specify experimental procedures as completely as possible. In no case does such identification imply a recommendation or endorsement by NIST, nor does it imply that any of the materials, instruments, or equipment identified are necessarily the best available for the purpose.

- All work presented has been reviewed and approved by the NIST Research Protections Office.

Forensic Genetics – Forensic DNA Typing Workflow

DNA Extraction → DNA Quantitation → PCR Amplification → Genotyping & Sequencing → Interpretation

Advancing technology and traceability through quality genetic measurements to aid work in Forensic and Clinical Genetics.

Variations upon the polymerase chain reaction (PCR) technique such as **rapid PCR, multiplex PCR, real-time PCR, and digital PCR** are used to **genotype, sequence, and provide quantitative information** pertaining to an organism's genome.

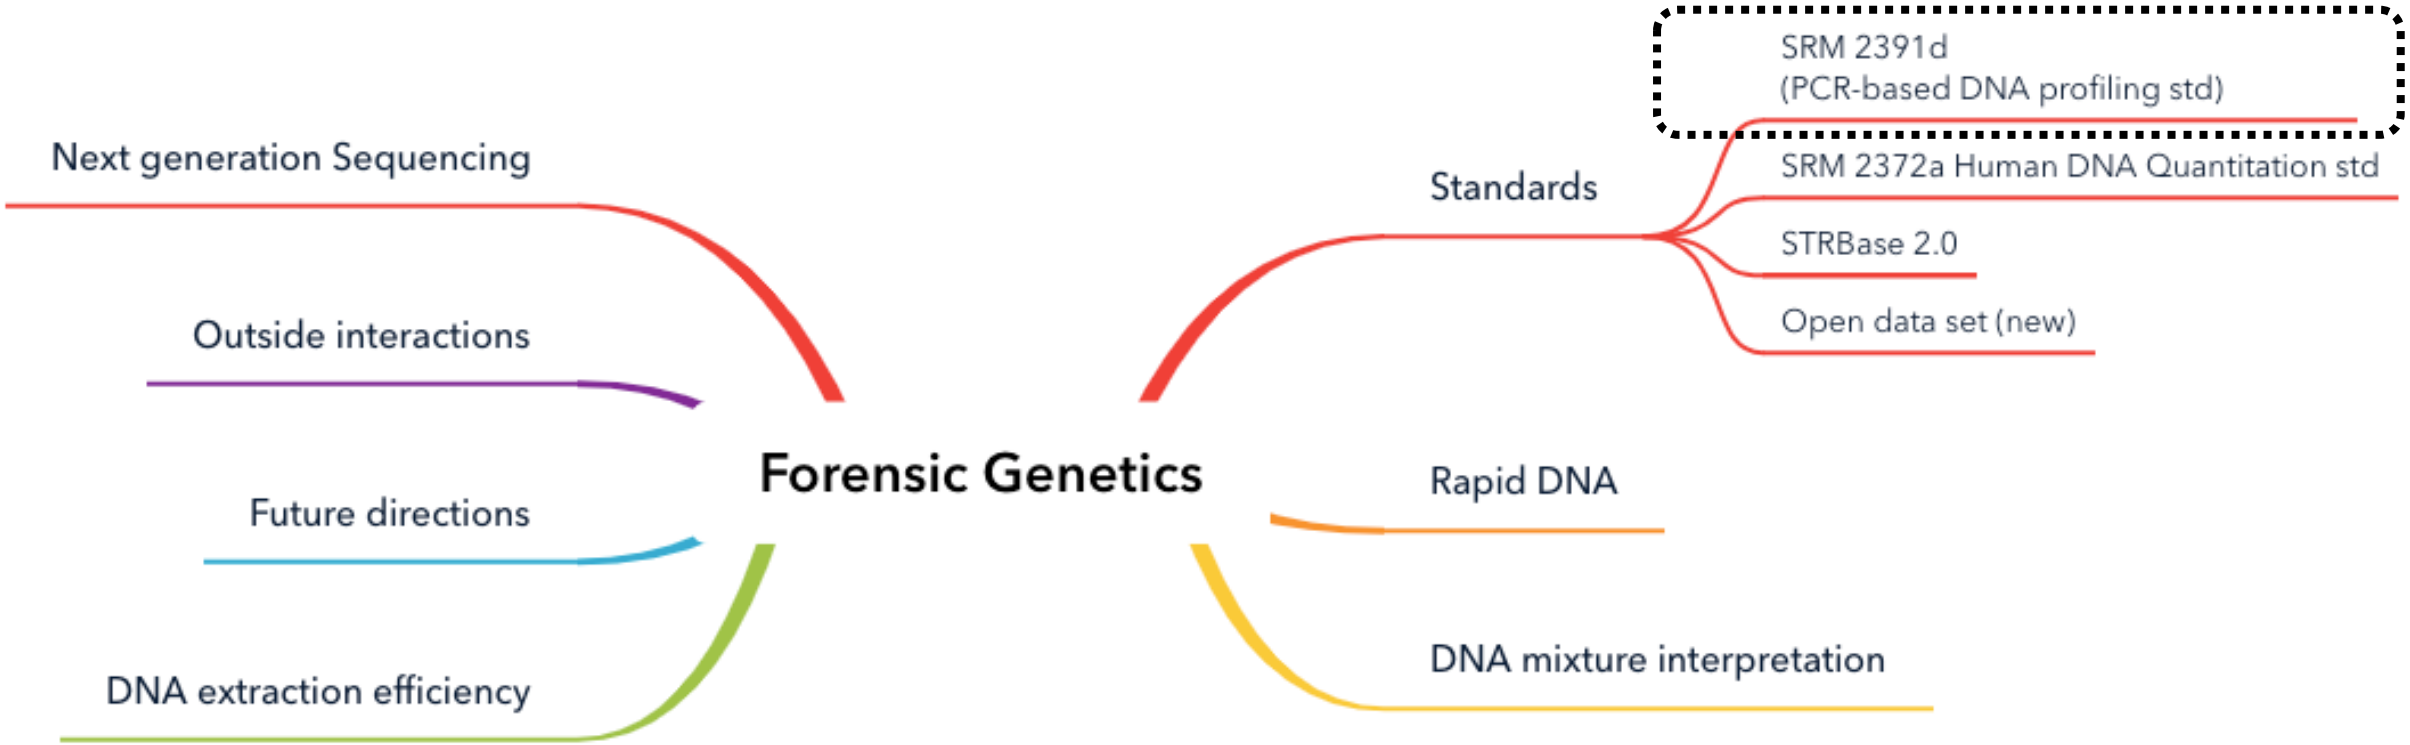
DNA Workshop Agenda
November 09, 2020

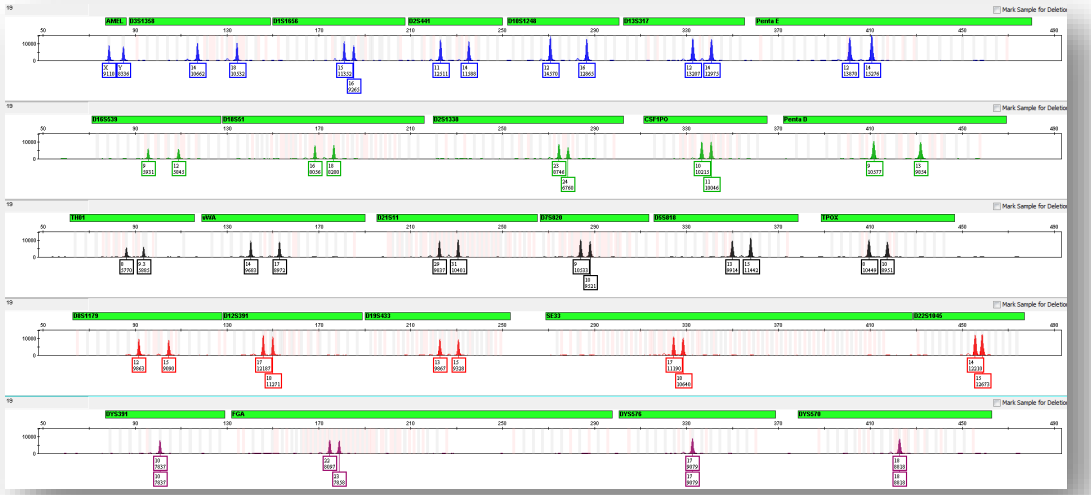
Time Slot	Title	Speaker	Time (mins)
10 – 10:15 am	Welcome and Introduction to the Applied Genetics Group	Peter Vallone	15
10:20 – 10:50 am	Not your standard Standard: Using SRM 2391d: PCR-Based DNA Profiling Standard in Your Lab	Becky Steffen	30
10:55 – 11:25 am	Making the best use of all of your curves: SRM 2372a Human DNA Quantitation Standard	Erica Romsos	30
11:30 – 12:00 pm	A Tour of STRBase 2.0	Lisa Borsuk	30
12:00 – 1:00 pm	Lunch Break		60
1:00 – 1:30 pm	Exploring DNA Interpretation Software Using the PROVEDIt Dataset	Sarah Riman	30
1:35 – 2:05 pm	Sequencing Workflows for Forensics	Peter Vallone	30
2:10 – 2:40 pm	SNPchat: the forensic marker that could be your BFF	Katherine Gettings	30
2:45 – 3:15 pm	Mitochondrial DNA Sequencing: the Next Generation	Kevin Kiesler	30
3:20 – 4:00 pm	AGG Panel: Q & A	all	40

Topics for today



SRM 2391 series

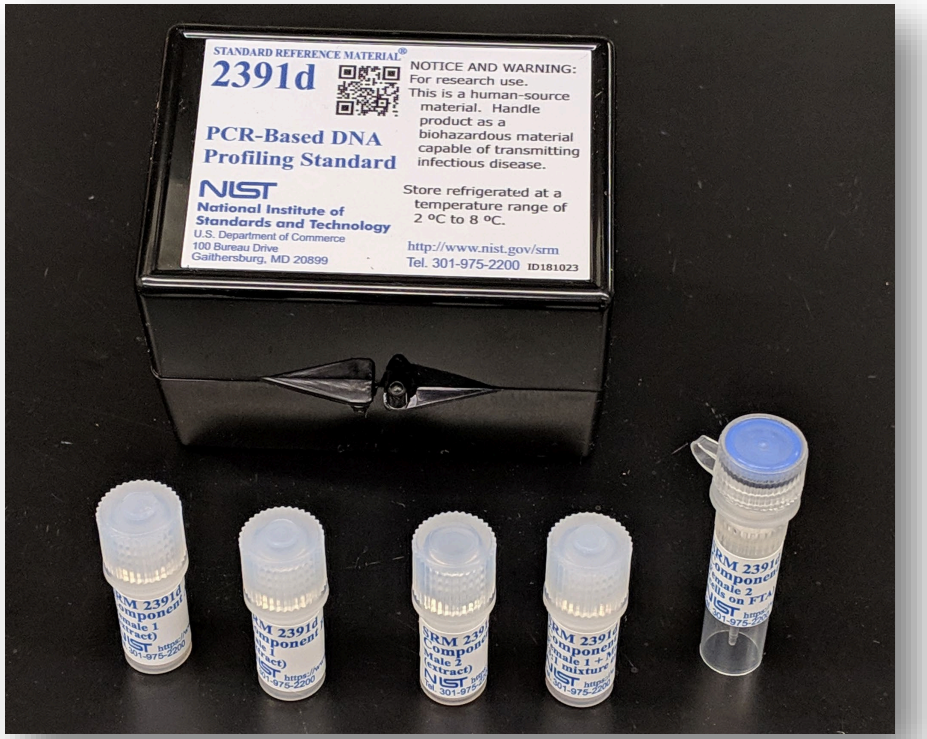
- SRM 2391c and 2391d – PCR-based DNA standard
- Used by the community to calibrate STR typing methods
- Purchased by practitioners and companies performing validations
- Further characterization of the samples and updates to the certificate



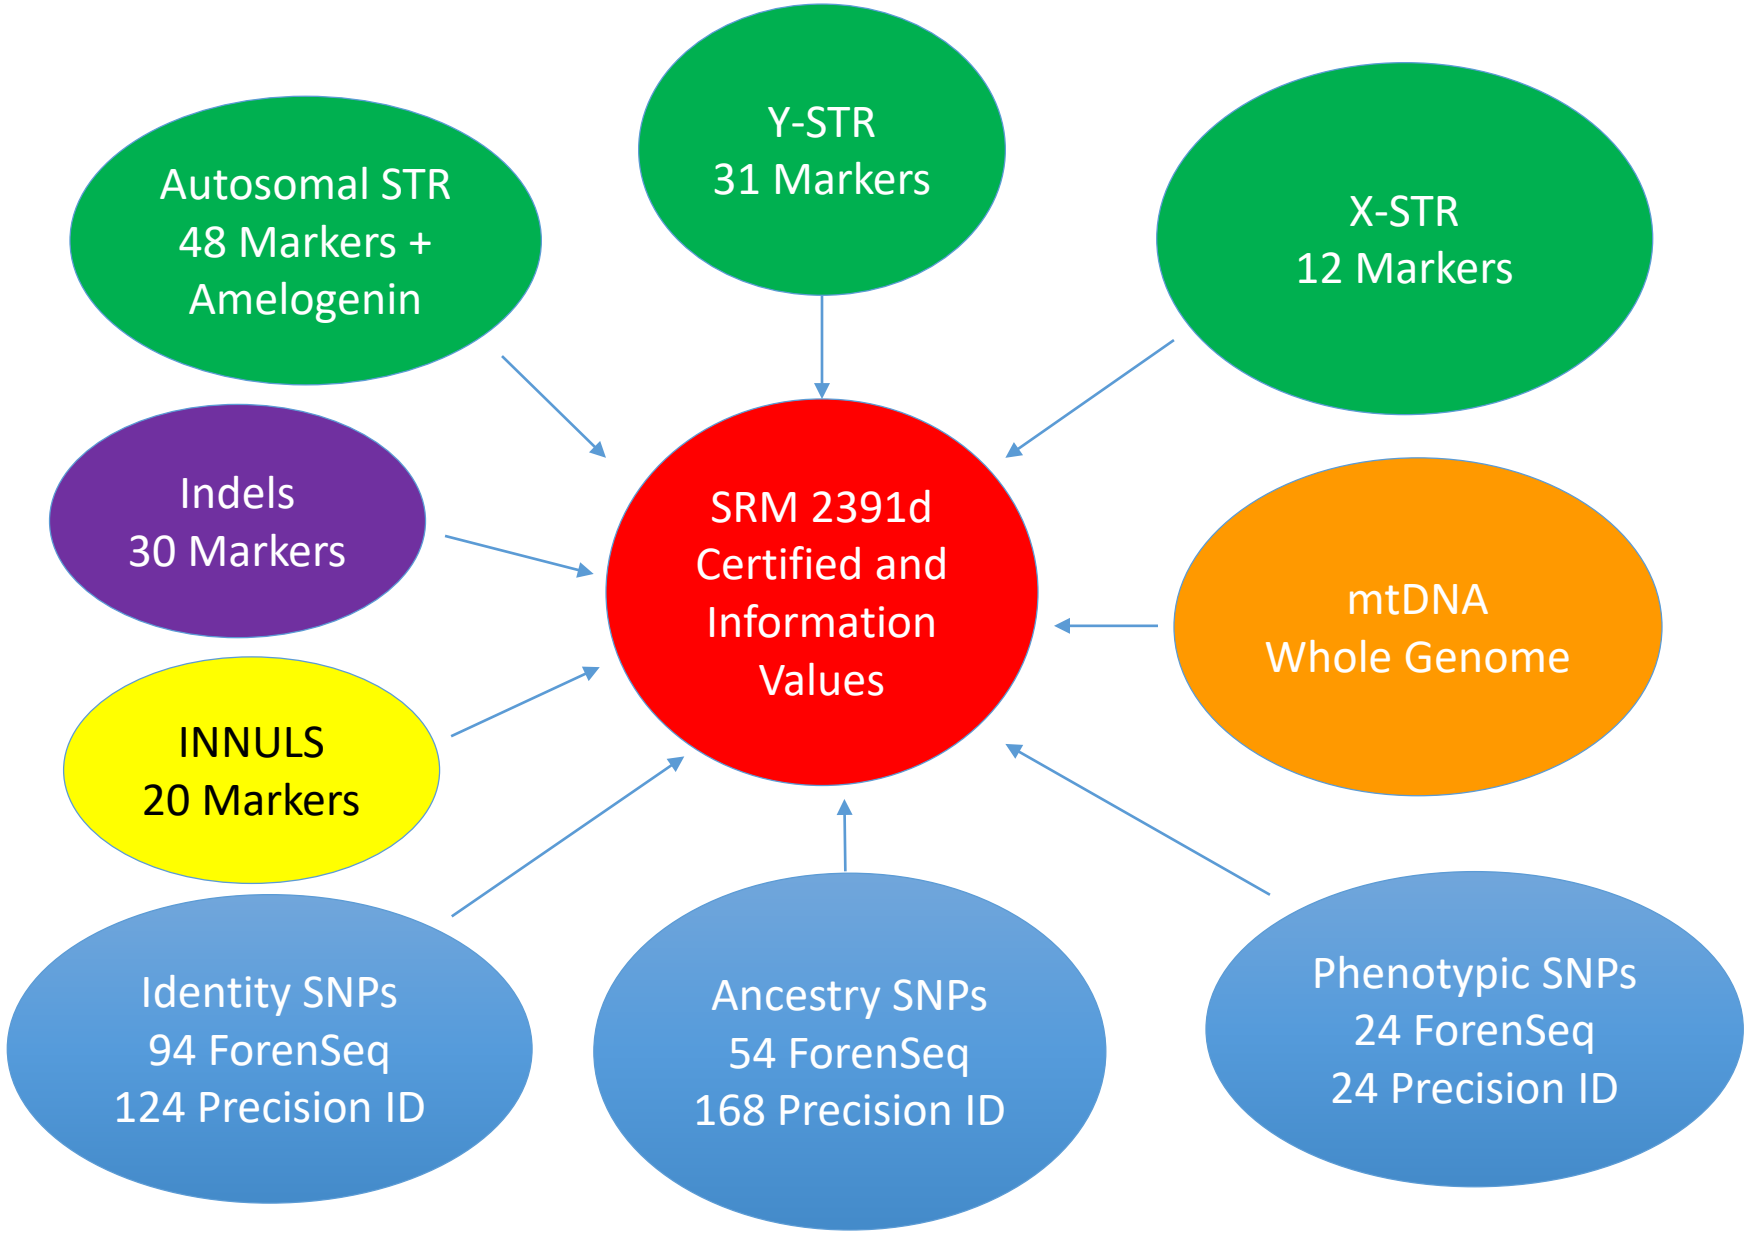
STR profile – certified allele calls

Table 1. Description of Components in SRM 2391d

Component	Description	Volume	Concentration[a]
A	Anonymous single-source female genomic DNA in TE^{-4} buffer	55 µL	1.6 ± 0.5 ng/µL
B	Anonymous single-source male genomic DNA in TE^{-4} buffer	55 µL	1.7 ± 0.5 ng/µL
C	Anonymous single-source male genomic DNA in TE^{-4} buffer	55 µL	1.6 ± 0.2 ng/µL
D	Mixed-source, 3:1 (3 parts Component A and 1 part Component C) genomic DNA in TE^{-4} buffer	55 µL	1.5 ± 0.4 ng/µL
E	Anonymous single-source female cells spotted on FTA paper[b]	Two 6 mm punches	7.5×10^4 cells per punch

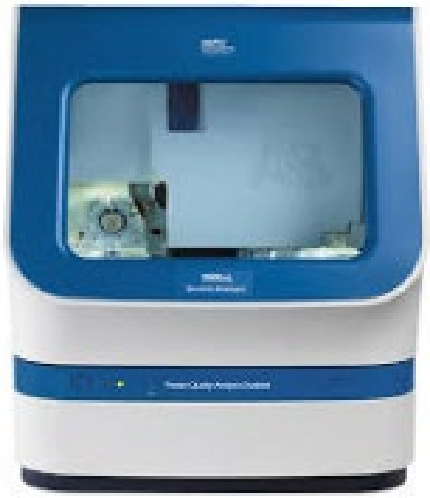


Markers included in the Certificate of Analysis



Platforms used for characterization

- **Capillary Electrophoresis (CE)** was performed with one instrument:
  - 3500xL Genetic Analyzer (Thermo Fisher)



3500xl

- **Next Generation Sequencing (NGS)** was performed with two different instruments:
  - MiSeq FGx (Verogen)
  - Ion S5 XL (Thermo Fisher)

MiSeq FGx

Ion S5 XL

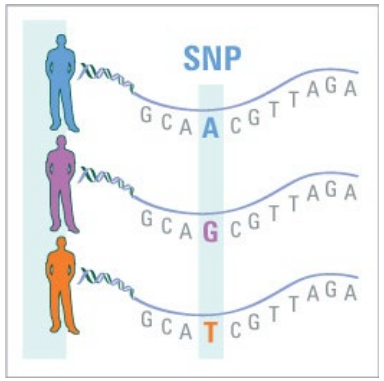
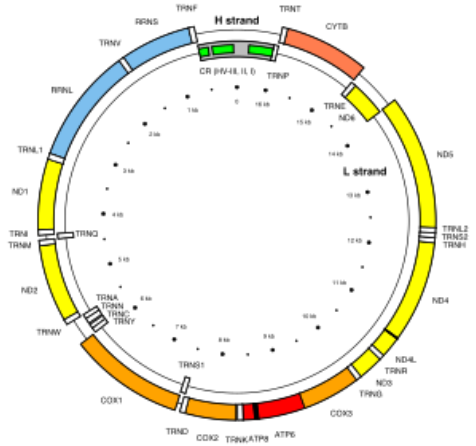
Information for additional marker systems

Support the adoption of new markers and technology platforms

- Mitochondrial genome sequence
- Identity SNPs – for degraded samples
- Ancestry SNPs – biogeographical ancestry prediction
- Phenotype SNPs – eye and hair color prediction





SNP allele calls for all components

Identity SNP markers

- 101 autosomal SNPs reported
  - ForenSeq (94)
  - Precision ID Identity Panel (90) + 34 Y-SNPs
- Forward strand genotype reported

83 identity autosomal SNPs in common

Ancestry and Phenotype SNP markers

- Ancestry/Phenotype SNPs 188 total
  - ForenSeq (78)
  - Precision ID Ancestry (165) and Phenotype Panel (24)
- Forward strand genotype reported

77 SNPs in common

Component	ForenSeq			Precision ID				Mito	Y SNP
	Ancestry	*Hair*	*Eye*	*Ancestry*	*Hair*	*Hair*	*Eye*		
A	European	0.68	0.66	European	0.66	1.00 light	0.67	T2b3	-

Predictions made using vendor tools for autosomal SNP markers

How can SRM 2391d be used in YOUR lab?

- To meet the FBI Quality Assurance Standards: QAS 8.4

> STANDARD 8.4 Newly validated DNA methods (from amplification through characterization), typing test kit, or platform instrument model shall be checked against an appropriate and available certified reference material (or sample made traceable to the certified reference material) prior to the implementation of the method for forensic analysis.

- Validation Studies: instrument, commercial kit, and software
  - Developmental and Internal Validations
  - Known, ***well-characterized*** samples for forensic marker systems

- Make NIST traceable materials: http://ts.nist.gov/traceability/

Establishing Traceability to NIST SRM 2391d

- Traceability requires the establishment of an unbroken chain of comparisons to stated references: http://ts.nist.gov/traceability/
- In the case of DNA testing with STR markers, the reference material is SRM 2391d
- Materials deemed traceable to NIST-created materials must have a record associated with them

'Lot' of DNA material

Run against SRM 2391d

Everyday use calibrant

Contact becky.steffen@nist.gov for traceability questions

Notes for SRM 2391c and Mitochondrial SRMs

- For those still using SRM 2391c (no longer being sold) the certificate expiration date has been extended through February 3, 2022
- This will be the final extension, after that SRM 2391d must be used
- SRMs 2392 and 2392-I (mitochondrial DNA sequencing) will not be replaced – use SRM 2391d

National Institute of Standards & Technology

Certificate of Analysis

Standard Reference Material® 2391c

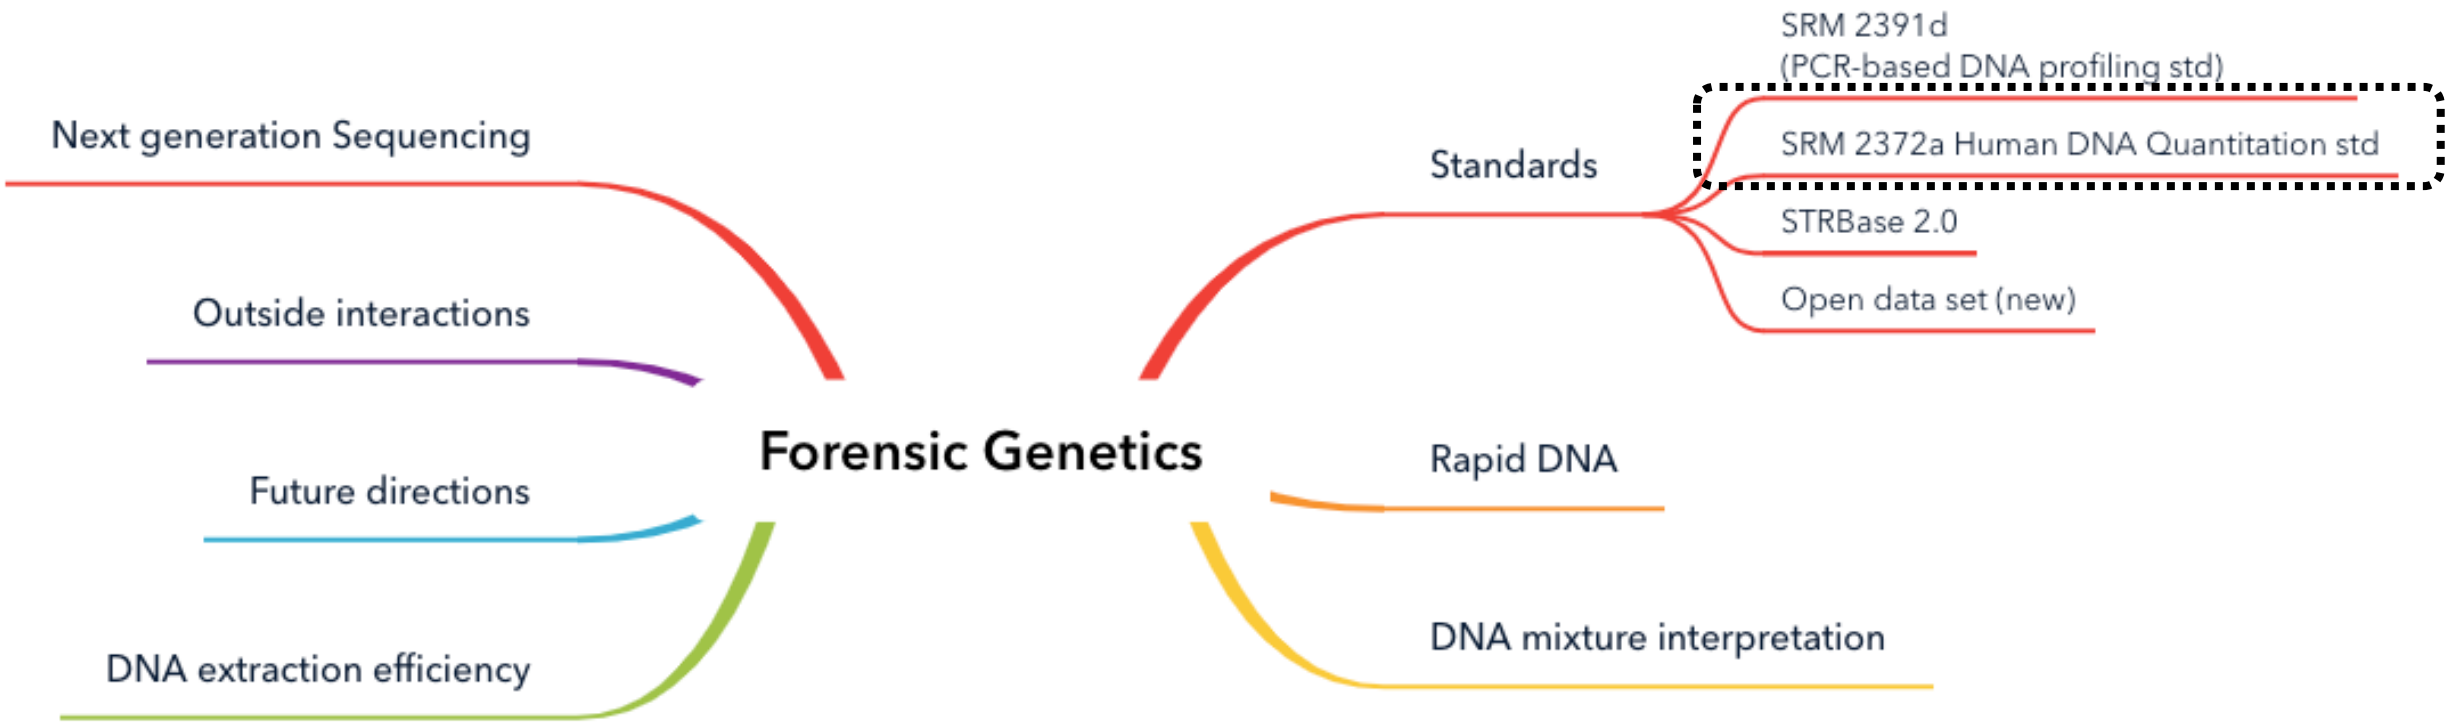
PCR-Based DNA Profiling Standard

Expiration of Certification: The certification of **SRM 2391c** is valid, within the measurement uncertainties specified until **03 February 2022**, provided the SRM is handled and stored in accordance with the instructions given in this certification (see "Instructions for Use"). The certification is nullified if the SRM is damaged, contaminated, or otherwise modified.

Details	
Description:	Mitochondrial DNA Sequencing (Human HL-60 DNA)
Lot:	N/A
Expiration Date:	3/31/2023
Unit Price * :	$622.00
Unit of Issue:	each
Status:	Now Selling See 'Additional Information' for details.
Certificate Date:	2/2/2018
Certificate Revision Date:	02 February 2018 (Change of certification period; editorial changes).
MSDS Date:	2/2/2018
Technical Contact:	Peter Vallone
Additional Information:	SRM 2392-I will not be replaced when the current stock is depleted. SRM 2391d PCR-Based DNA Profiling Standard now contains mitochondrial sequence information and should be considered as a replacement.

SRM 2392-I will not be replaced when the current stock is depleted. SRM 2391d PCR-Based DNA Profiling Standard now contains mitochondrial sequence information and should be considered as a replacement.

Topics for today



SRM 2372a (Human DNA Quantitation Std)

- SRM 2372a – Human DNA Quantitation Standard
- Used to calibrate qPCR methods and commercial DNA standards
- Digital PCR used for value assignment
- Mitochondrial to nuclear DNA ratio information included

Table 1. Certified Values of Number and Mass Concentration for SRM 2372a[a]

The copy number values are metrologically traceable to the natural units count 1 and ratio 1 and International System of Units (SI) derived units of volume. The DNA mass concentration values are metrologically traceable to the natural units count and ratio 1 and SI derived units of mass and volume.

Component	Copy Number[b] (per nL)	DNA[c] (ng/µL)
A (red cap)	15.1 ± 1.5	49.8 ± 5.0
B (white cap)	17.5 ± 1.8	57.8 ± 5.8
C (blue cap)	14.5 ± 1.5	47.9 ± 4.8

Callaghan,[5] Ph.D.; Joanie Brocato,[6] Ph.D.; Janaki Vaidyanathan,[6] M.S.; Juan C. Pedroso,[7] A.A.; Andrea Amy,[7] B.S.; Stephanie Stoiloff,[8] M.S.; Victor H. Morillo,[8] P.S.M.; Karina Czetyrko,[8] P.S.M.; Elizabeth D. Johnson,[9] M.S.; Jessica de Tagyos,[9] M.S.F.S.; Ashley Murray,[9] B.S.; and Peter M. Vallone,[1] Ph.D.

Results of the 2018 Rapid DNA Maturity Assessment*

TABLE 1—*Samples tested across nine participating agencies*

Instrument	Chemistry	Independent Instruments	Total Samples Tested	Analysis Method
ANDE 6C System	FlexPlex	5	100	Rapid DNA Analysis
RapidHIT 200	GlobalFiler Express	3	60	Modified Rapid DNA Analysis
RapidHIT ID	GlobalFiler Express	4	80	Modified Rapid DNA Analysis

What is "Rapid DNA"?

A fully automated instrument capable of generating a DNA profile from a swab ('swab in – profile out')

The maturity assessment was an interlaboratory study assessing DNA typing success and accuracy results on three Rapid DNA platforms

Twenty swabs were provided to each participant (crime labs, **police agencies**, **vendors**)

The results support the implementation of Rapid DNA instrumentation at the booking stations for single source samples

Stakeholders: FBI laboratory, DNA databasing labs, booking stations, Rapid DNA community, ANDE, Thermo Fisher

Assessment Scheme

Participant Runs RH-ID GFE

- Participants may choose one chemistry per ***20*** NIST provided swabs
- Additional packages may be requested

NIST provides **20** reference buccal swabs to each participant

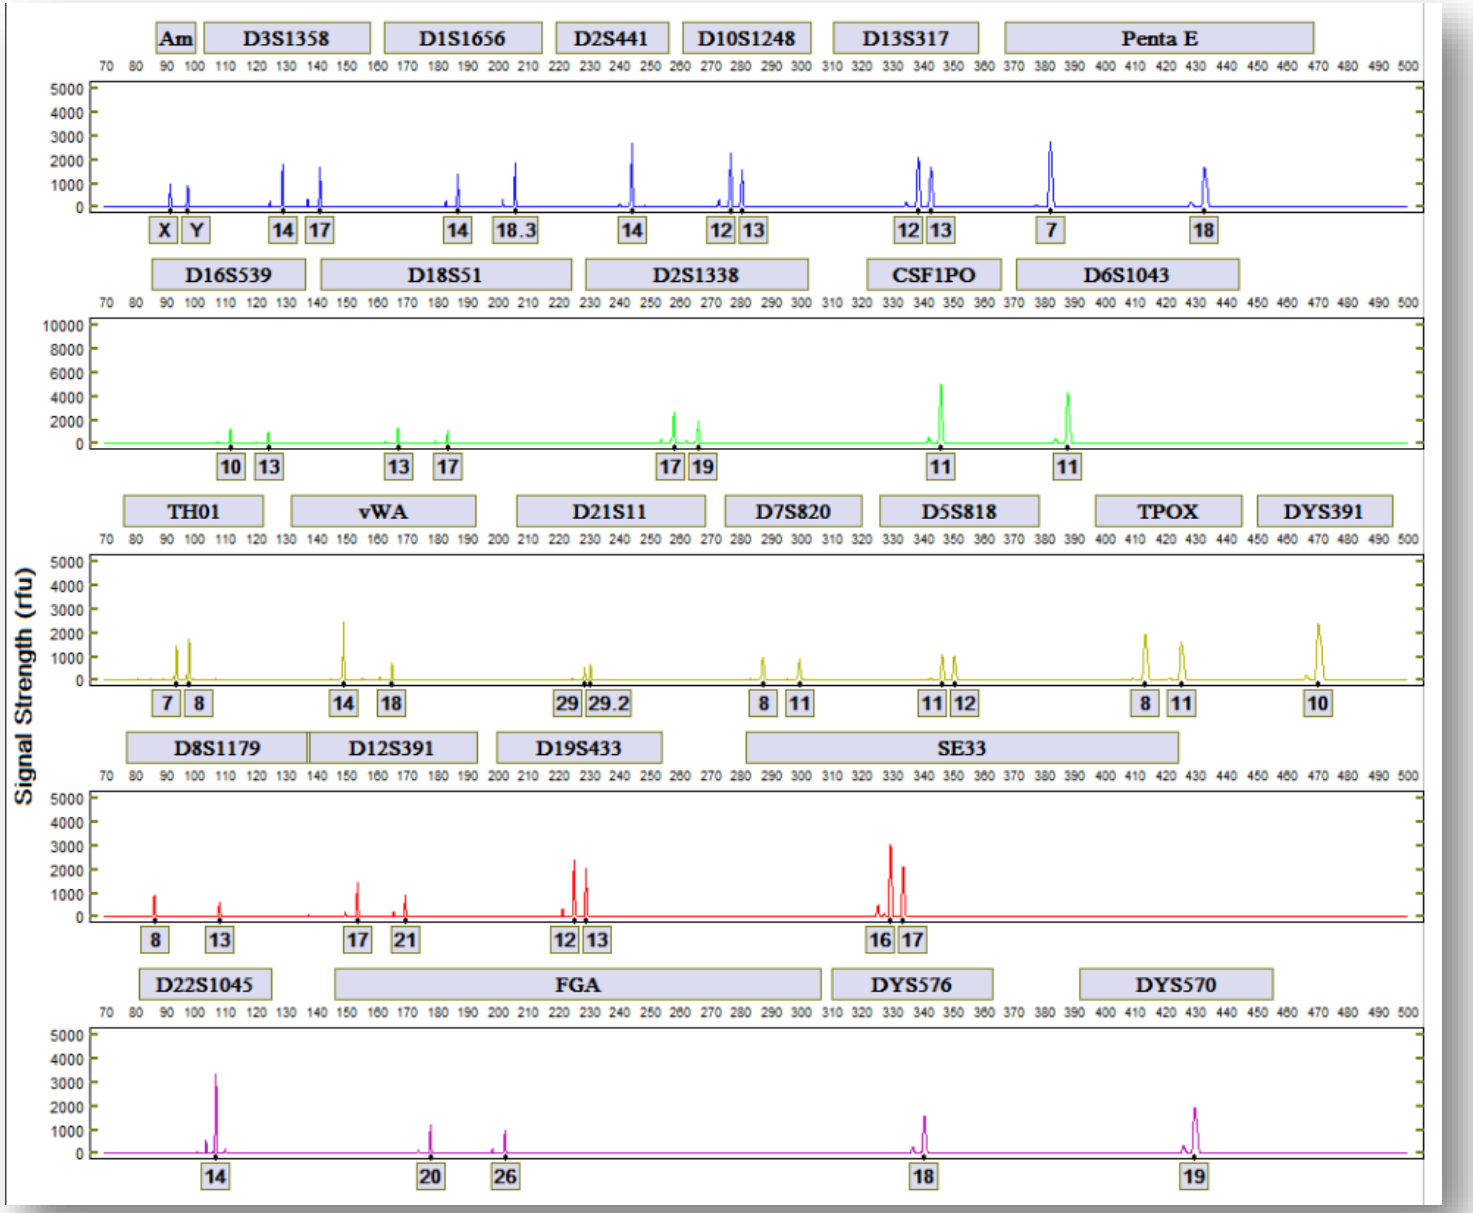
Participant Runs RH200 GFE

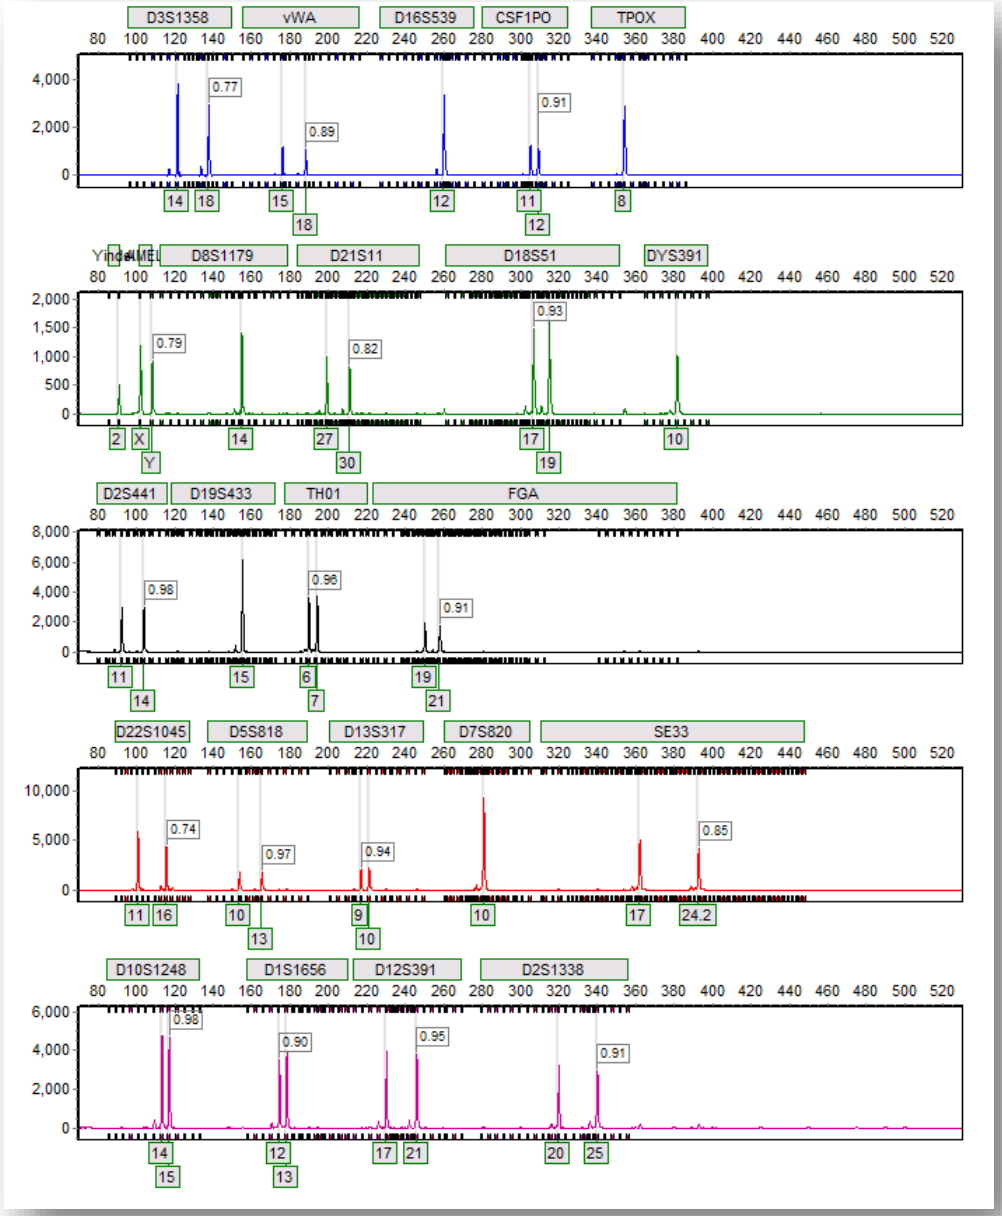
NIST reports CODIS 20 success rate for all data combined (% success)

Data transferred back to NIST via electronic format

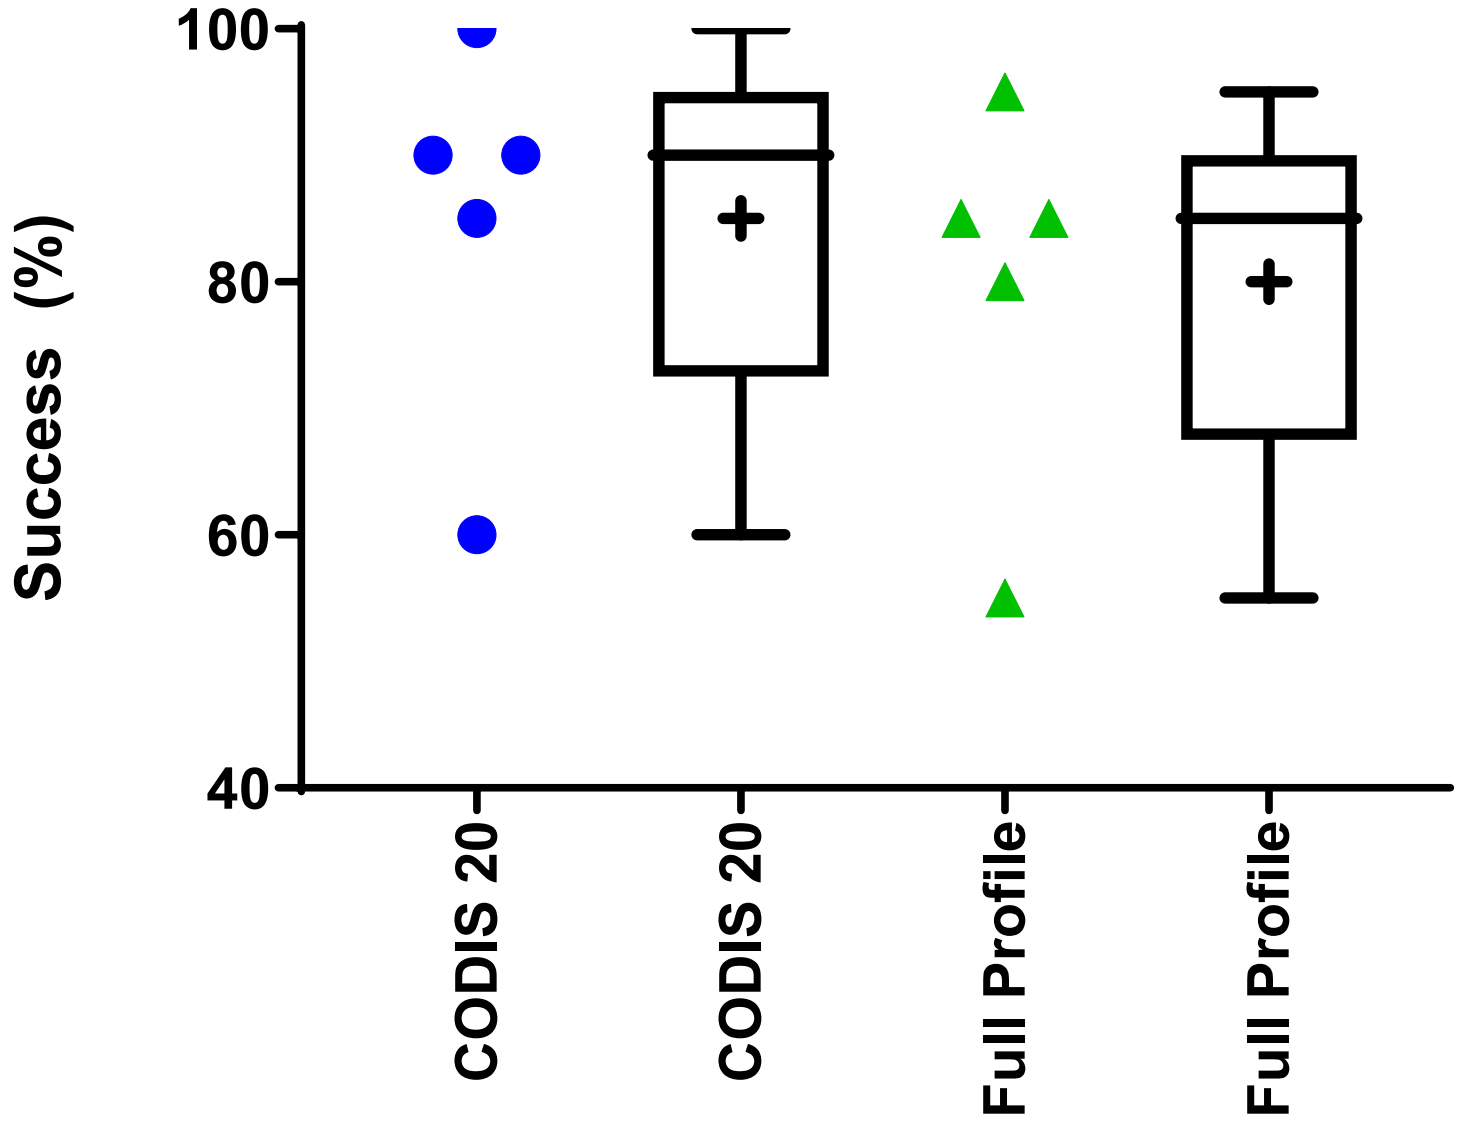
Participant Runs ANDE FlexPlex

Profiles from ***high quality single source*** samples generated by Rapid DNA instruments





Genotyping Success: Rapid DNA Analysis

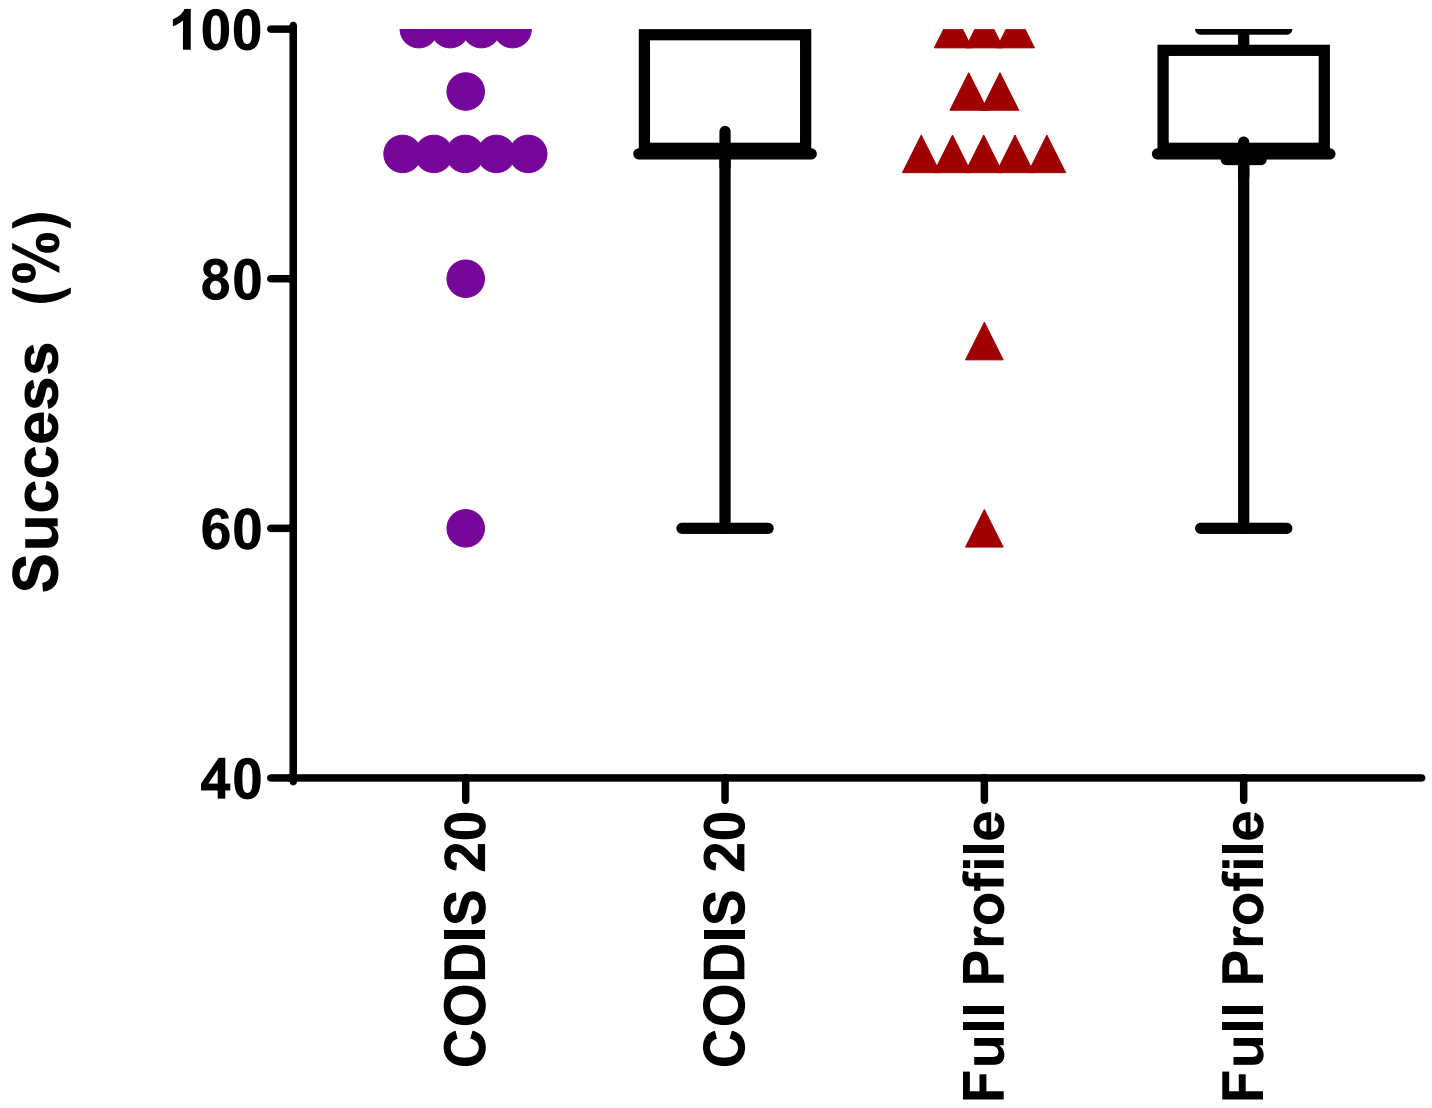


CODIS 20: 85%

Full Profile: 80%

Each data point is an independent instrument

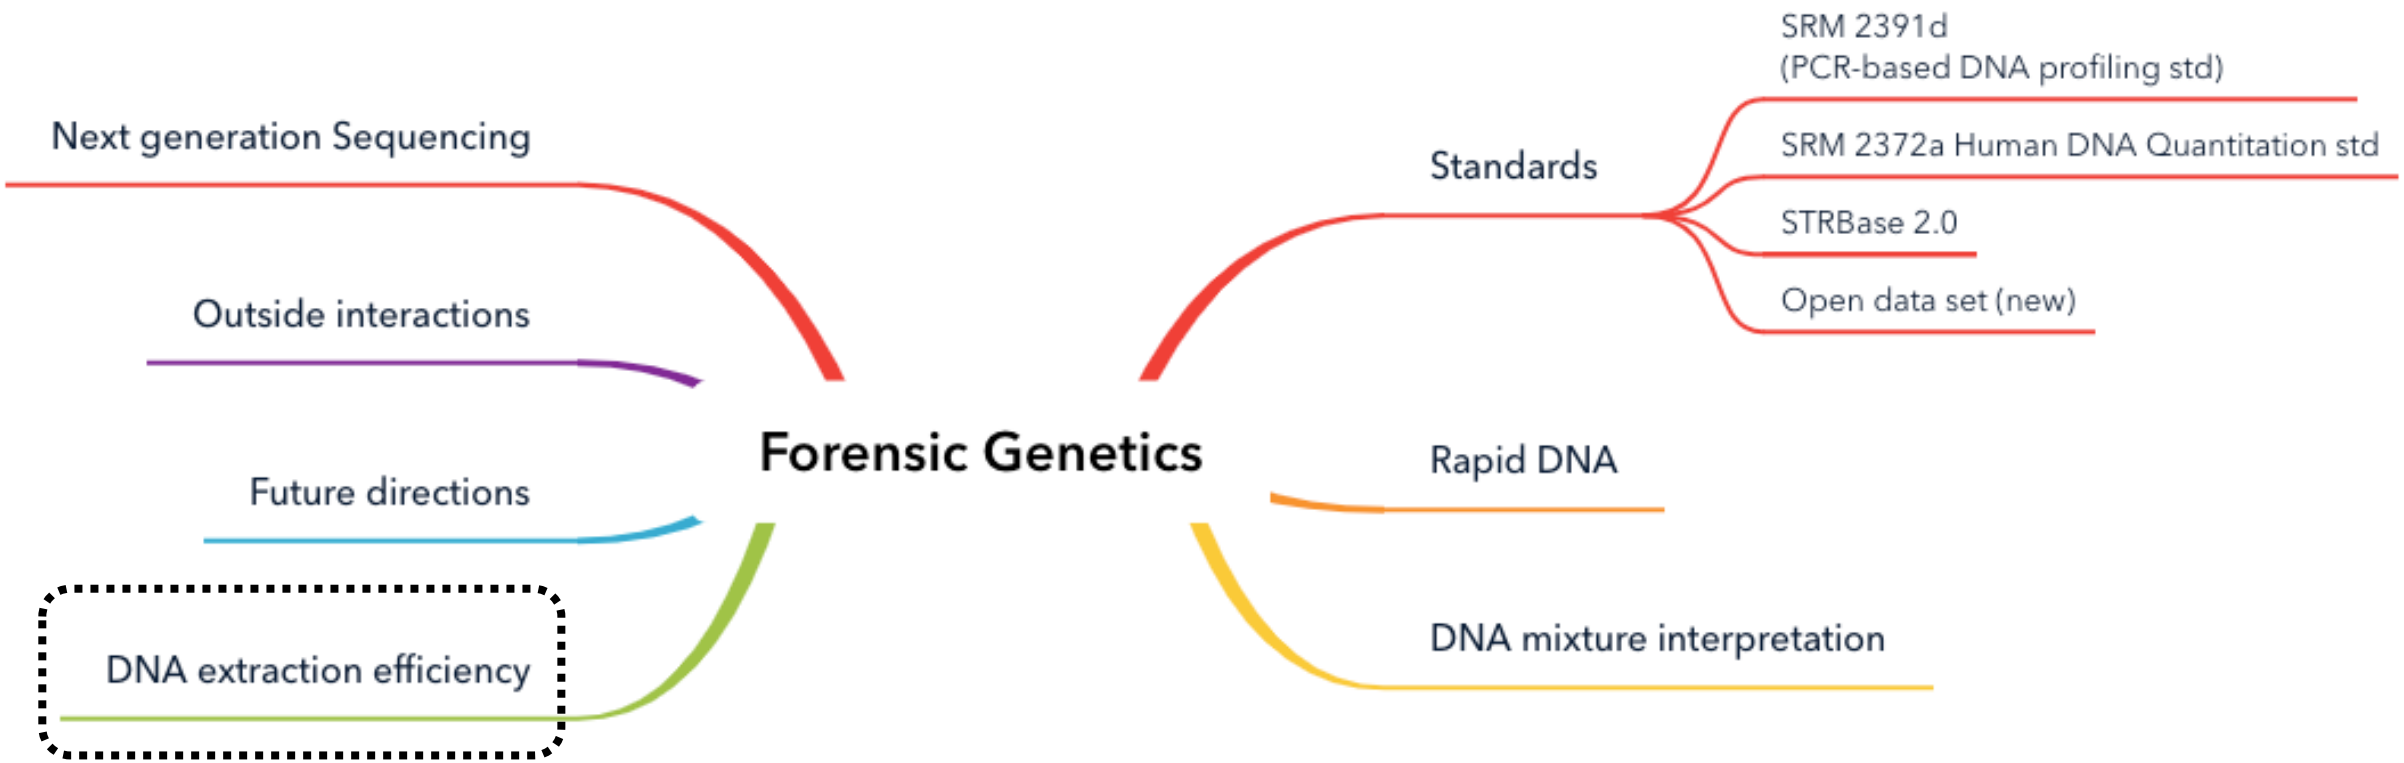
Genotyping Success: Modified Rapid DNA Analysis



CODIS 20: 90%
Full Profile: 90%

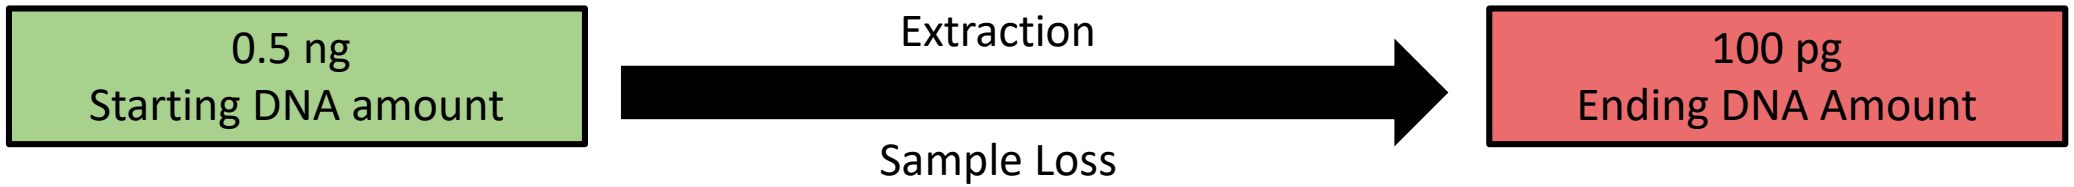
Each data point is an independent instrument

Topics for today



Examination of Front-End Methods in DNA Typing

- Problem: Assess the amount of sample loss during the extraction
  - Low extraction efficiency cold result in overall lower sample quantity
  - May fail to yield full STR profiles or minor components in mixtures



Methods for determining extraction efficiency and sample loss vary

Absolute Extraction Efficiency

$$\frac{\text{DNA Recovered}}{\text{Original Amount DNA}} = \text{Absolute Extraction Efficiency}$$

Measured by digital PCR

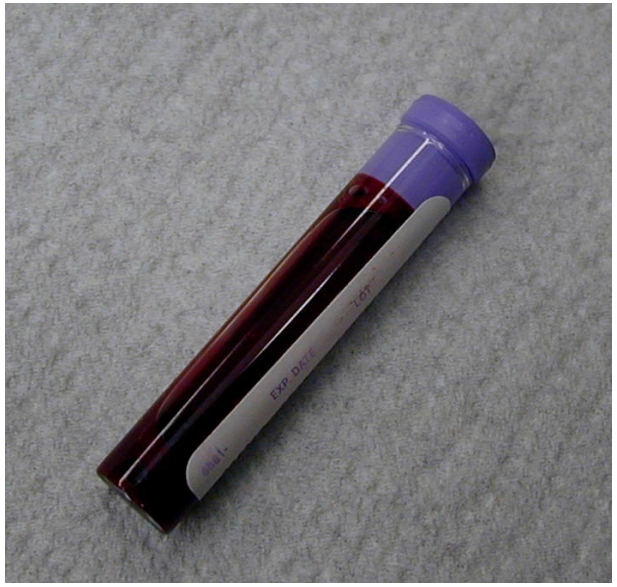
Offers the ability to evaluate individual extraction processes and their efficiency independent of another method

DNA Sources

Component A of SRM 2372a: Human DNA Quantitation Standard

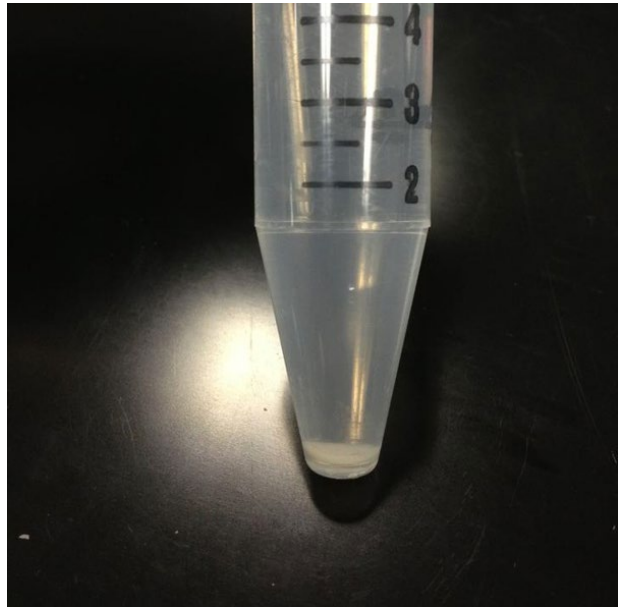
Known concentration of 49.8 ng/µL
Determined by digital PCR

Freshly collected whole blood



Known WBC of 4.6 x10³ per µL
WBC reported by blood bank

Washed cell suspension in dPBS

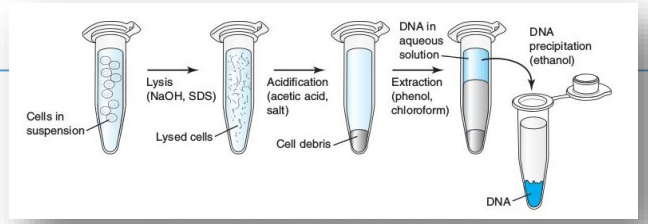


Known cell count of 1x10⁶ per mL
Determined by flow cytometry

DNA Extraction Methods

Phenol Chloroform (Organic)

- Often referred to as the "gold standard"
- Proteinase K digestion of the cells
- Equal volumes of Phenol Chloroform added
- Phase lock gel tubes used for promoting separation
- DNA was precipitated with Ethanol and resolubilized with TE^{-4} buffer



QIAamp Spin Columns

- Manual method commonly used in forensic DNA laboratories
- Silica columns for collection of DNA
- Elution in proprietary buffer
  - Similar to TE^{-4}

Qiagen EZ1 Advanced XL

- Robotic purification instrument
- Cell lysis takes place on the benchtop in a thermomixer
- Purification with paramagnetic bead collection
- Elution in TE^{-4}

Extraction methods available in our lab

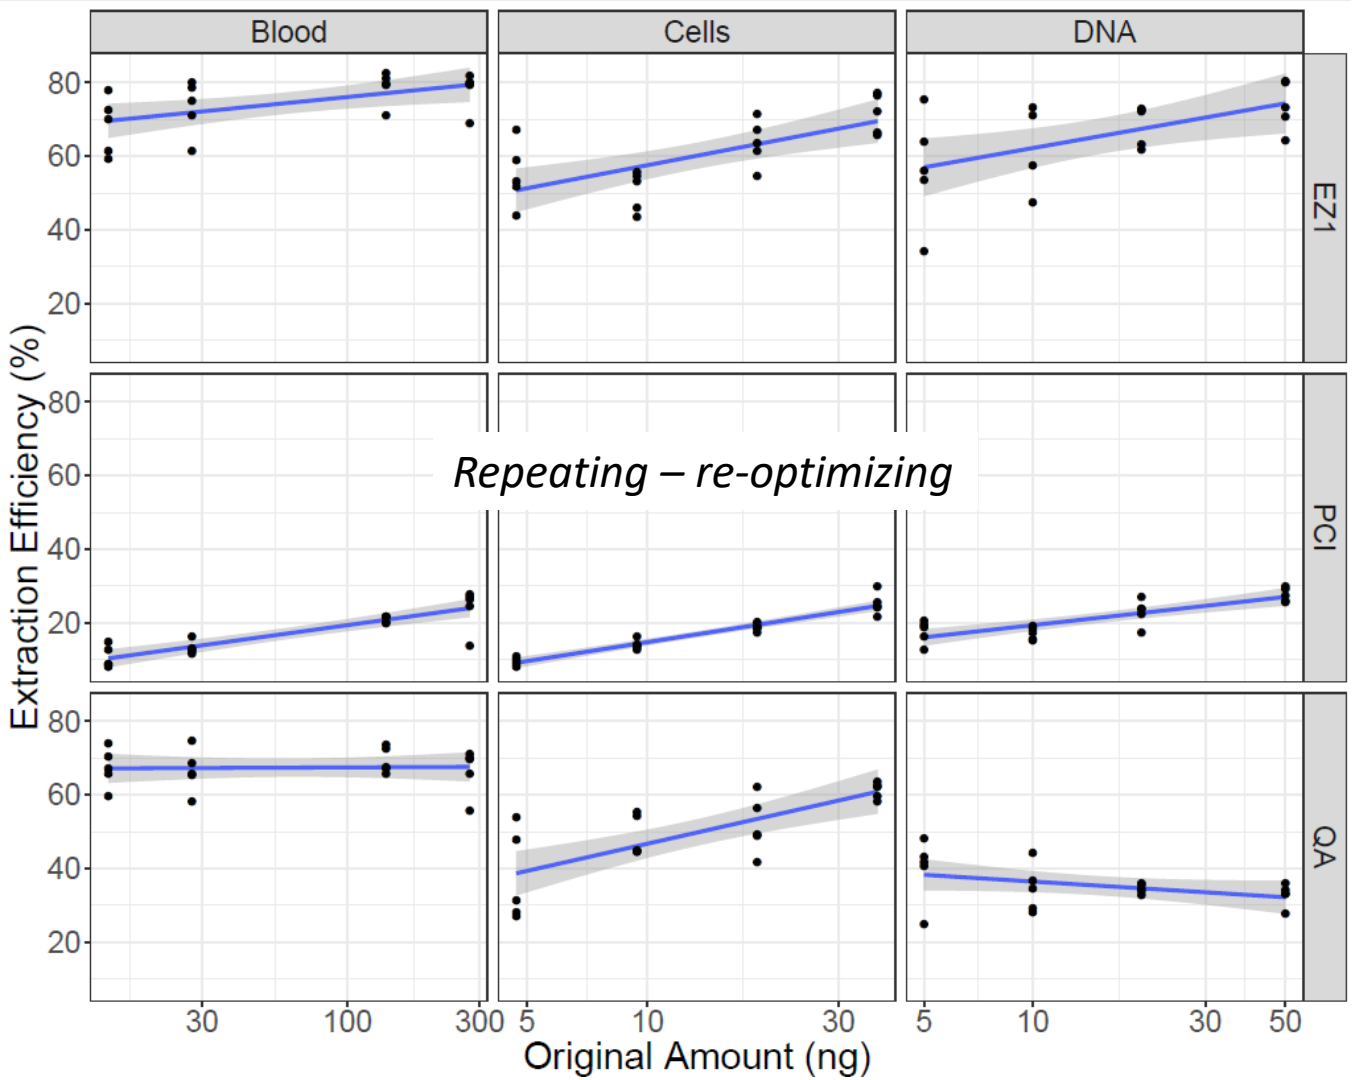
Four DNA input amounts were tested in replicates of five for each extraction method

60 Samples per DNA Source

	Amount (ng)	# of Cells	Uncertainty (± # Cells)	# of Replicates
Extracted DNA	50	8,333	833	5 per amount (20 per DNA Source)
	20	3,333	333	
	10	1,667	167	
	5	781	78	
Cells	38	6,250	313	5 per amount (20 per DNA Source)
	19	3,125	156	
	9	1,563	78	
	5	781	39	
Blood	276	46,000	2,300	5 per amount (20 per DNA Source)
	138	23,000	1,150	
	28	4,667	233	
	14	2,333	117	

60 Samples per Extraction Method

DNA Source



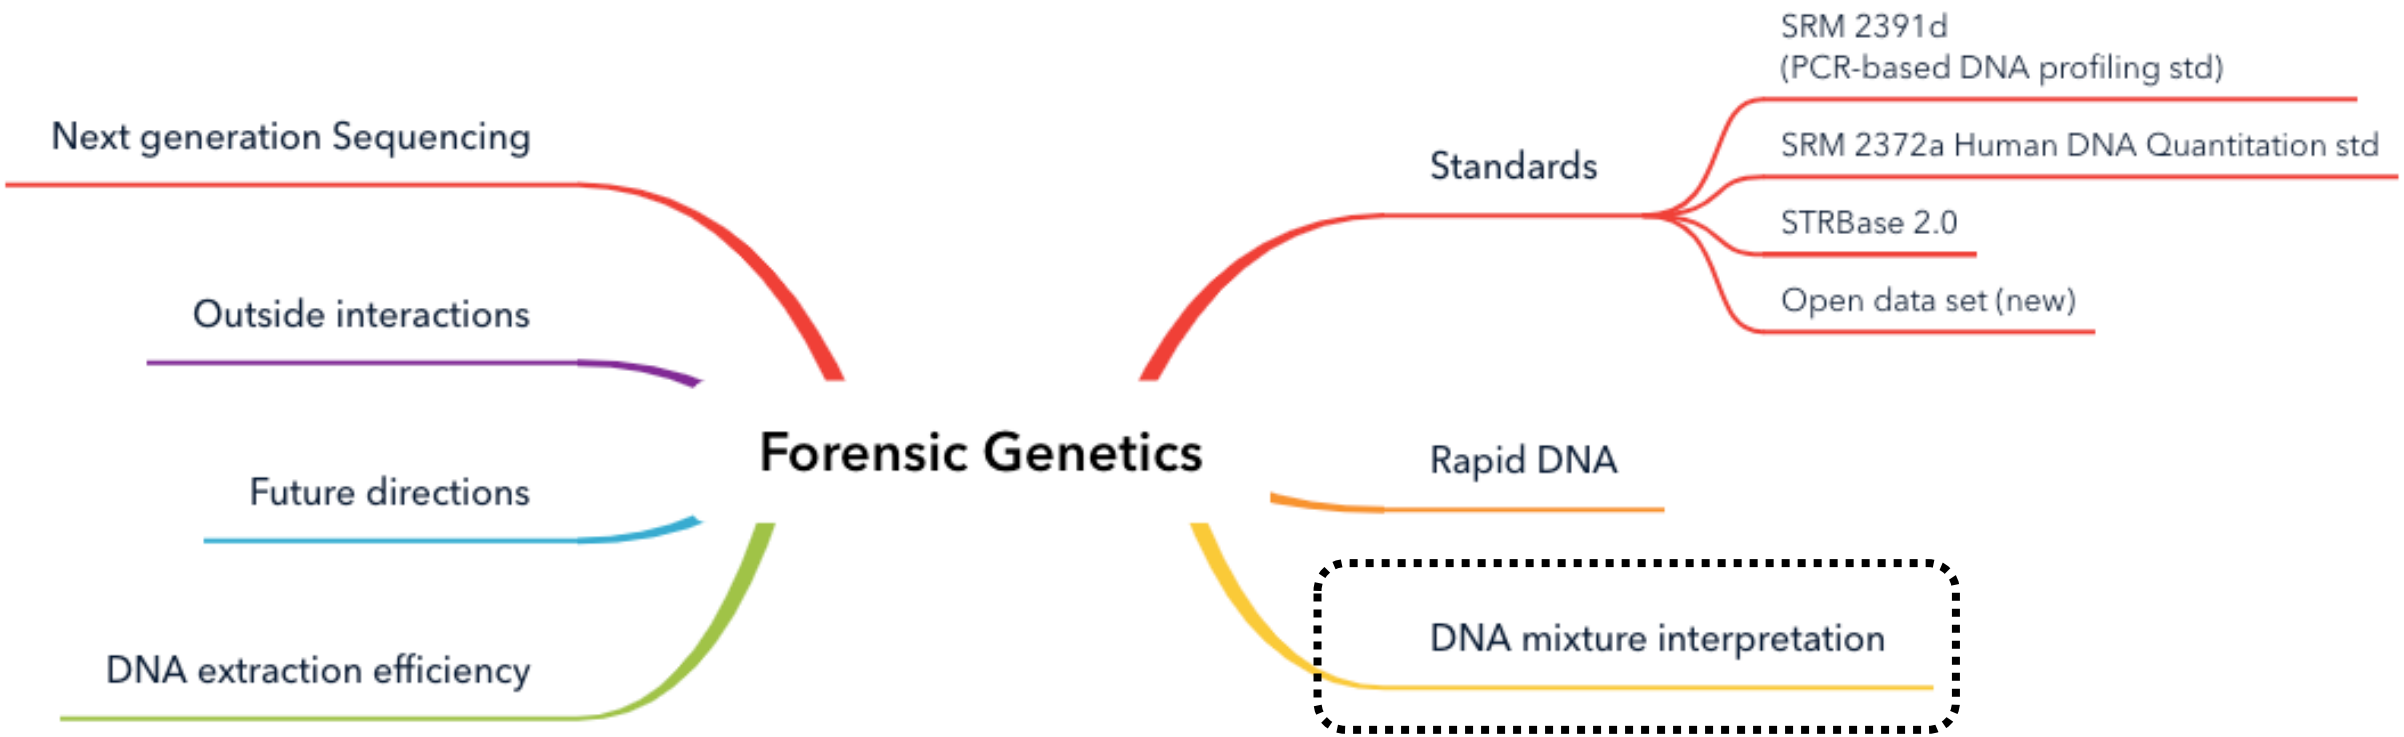
Extraction Method

Digital PCR was used to determine the concentration post-extraction

The efficiency of the extraction methods are shown between methods and DNA sources

Romsos, E.L & Vallone, P.M. (2019) Estimation of extraction efficiency by droplet digital PCR. Forensic Sci Int Genet. Sup. Ser. DOI: 10.1016/j.fsigss.2019.10.072

Topics for today



DNA Mixture Interpretation

LR system

DNA Extraction | DNA Quantitation | PCR Amplification | Genotyping & Sequencing | Interpretation

Statistics

measurement

Assign a strength of evidence
Likelihood ratio (LR)

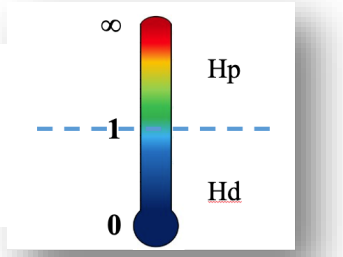
H_p: the DNA from the POI **IS** in the mixture

H_d: the DNA from the POI **IS NOT** in the mixture

I: background information

E: evidence

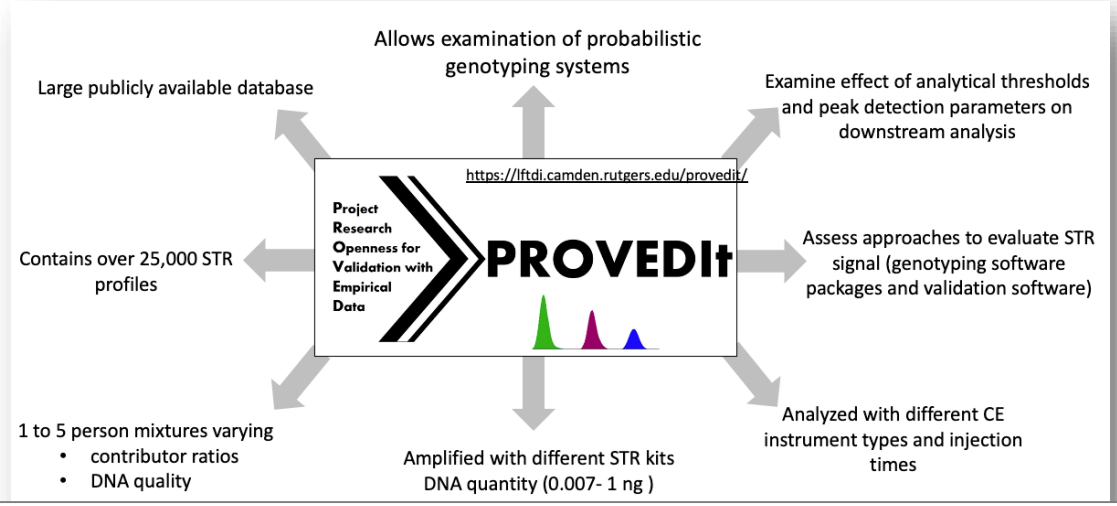
$$LR = \frac{Pr(E|Hp, I)}{Pr(E|Hd, I)}$$



DNA Mixture Interpretation

- Examine methods to assess the performance of LR systems using publicly available ground truth data (mixture profiles)

- Examine the similarities and differences between the LR systems

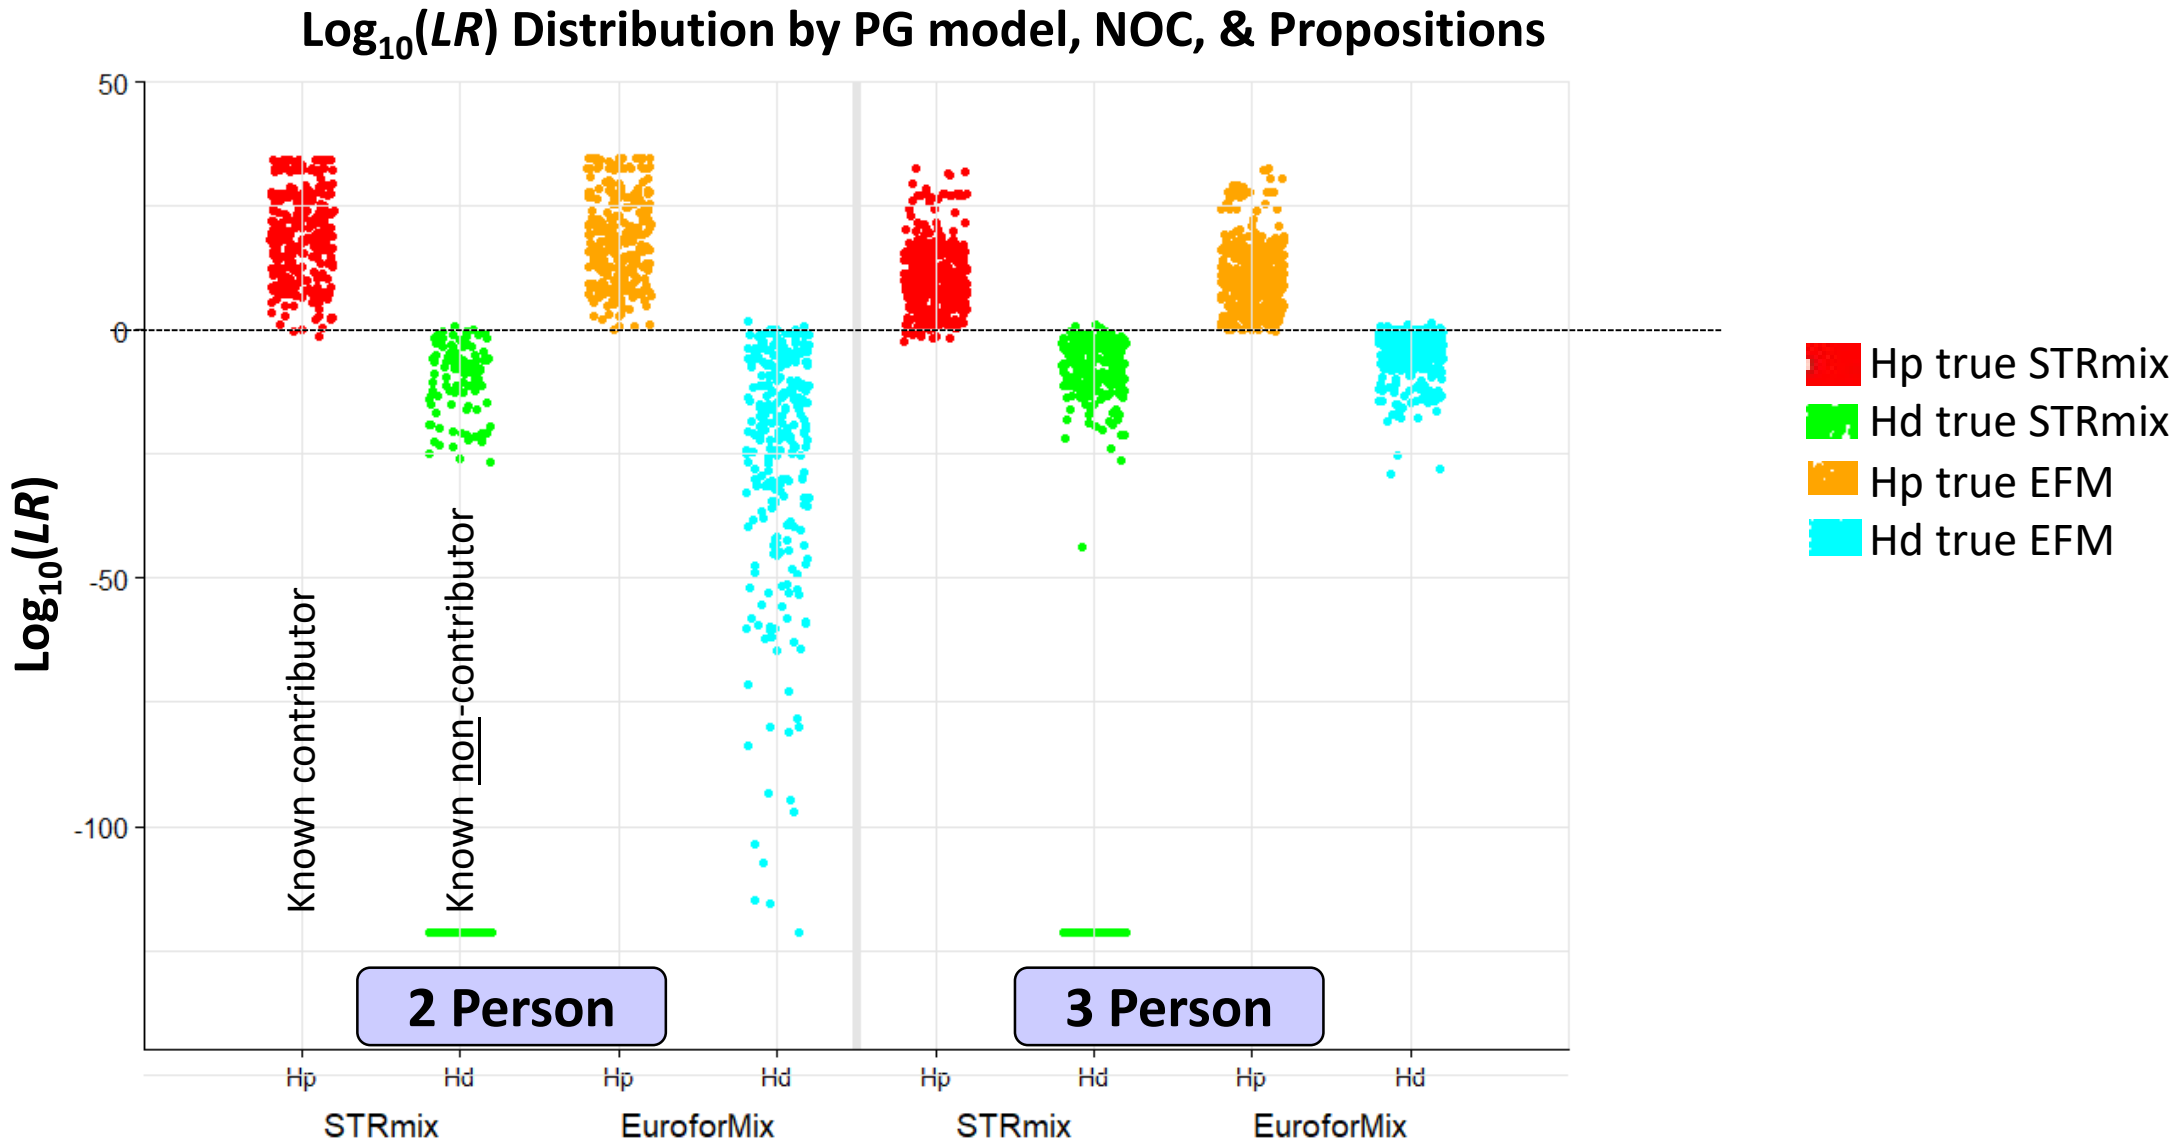


Alfonse, L.E., et al. A large-scale dataset of single and mixed-source short tandem repeat profiles to inform human identification strategies: PROVEDIt. Forensic Sci. Int. Genetics 32, 62-70.

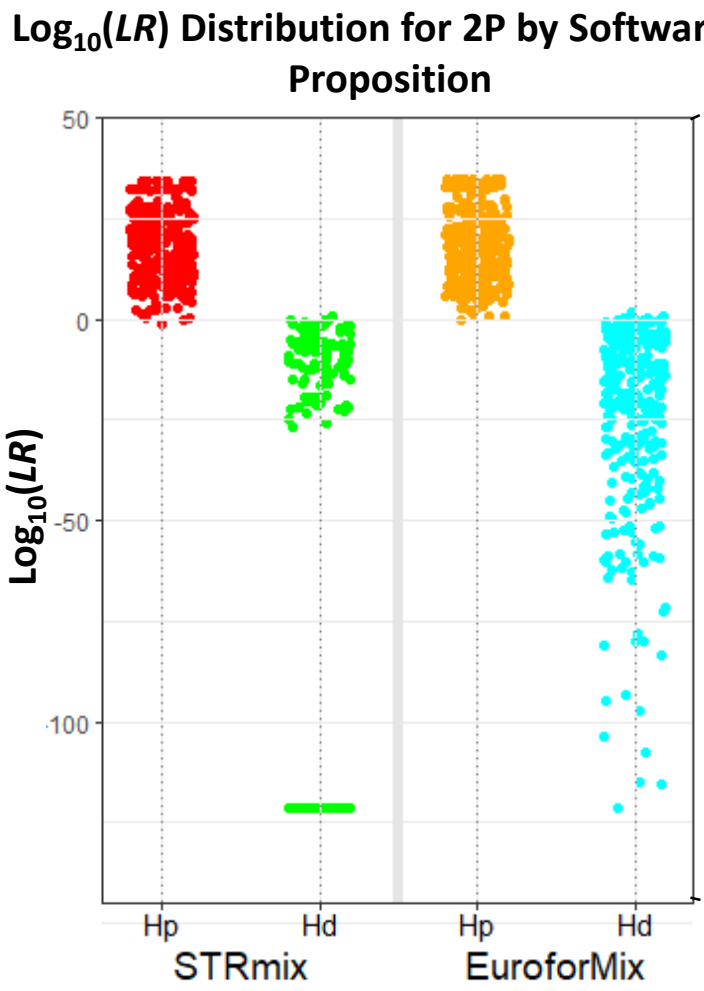
STRmix v2.6	EuroForMix v2.1.0
▪ N-1, N-2 and N+1 stutter peaks modeled ▪ Drop-in frequency = 0.0015 and maximum cap = 180 RFU ▪ Saturation threshold = 30,000 RFU ▪ MCMC settings: 8 chains of 100,000 burn-in accepts, 50,000 post burn-in accepts per chain ▪ > 300 single source profiles used for Model Maker ▪ Sub-source LR	▪ MLE (Maximum likelihood estimation) approach ▪ Degradation and stutter models on ▪ Default parameters except for a 35 RFU detection threshold, Pr(C) = 0.0015 and λ = 0.018. ▪ MLE based LR
https://www.strmix.com/	http://www.euroformix.com/

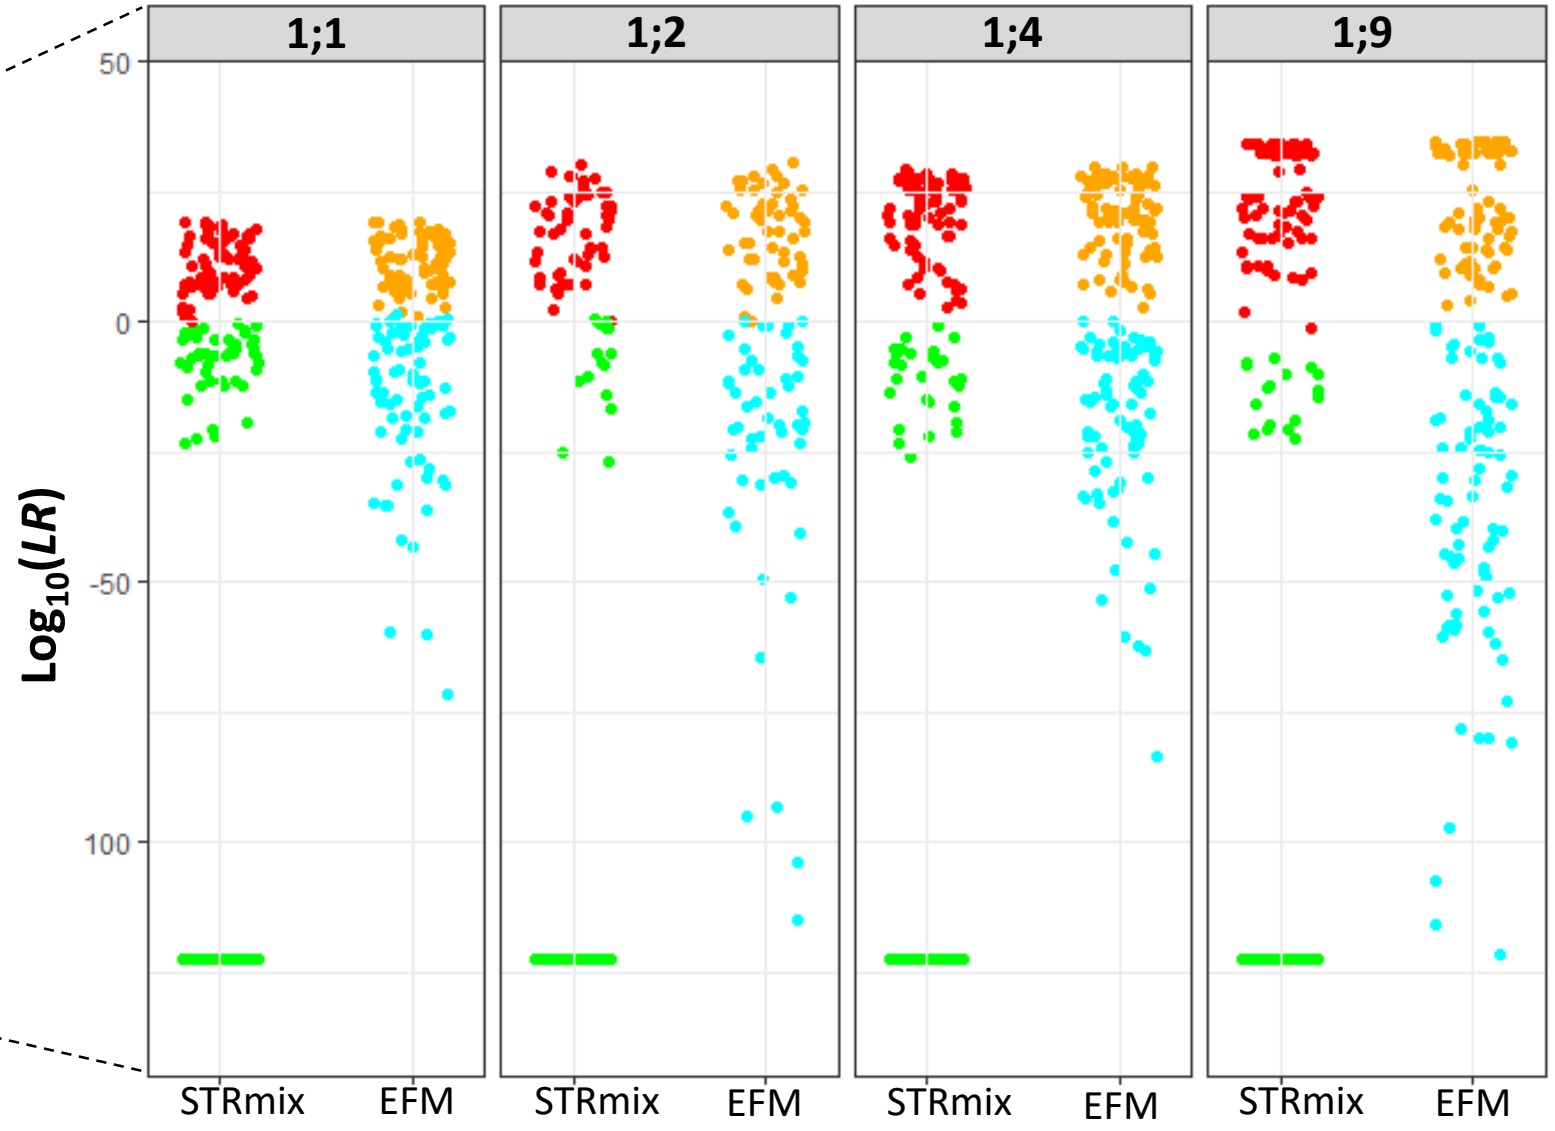
- Profiles were analyzed using the per dye ATs
- NIST 1036-Caucasian allele frequencies
- θ correction was applied using an F_{st} (θ) = 0.01
- True NOC and same propositions were used in both software

Discrimination power of LR Systems using Hp true & Hd true LR distribution

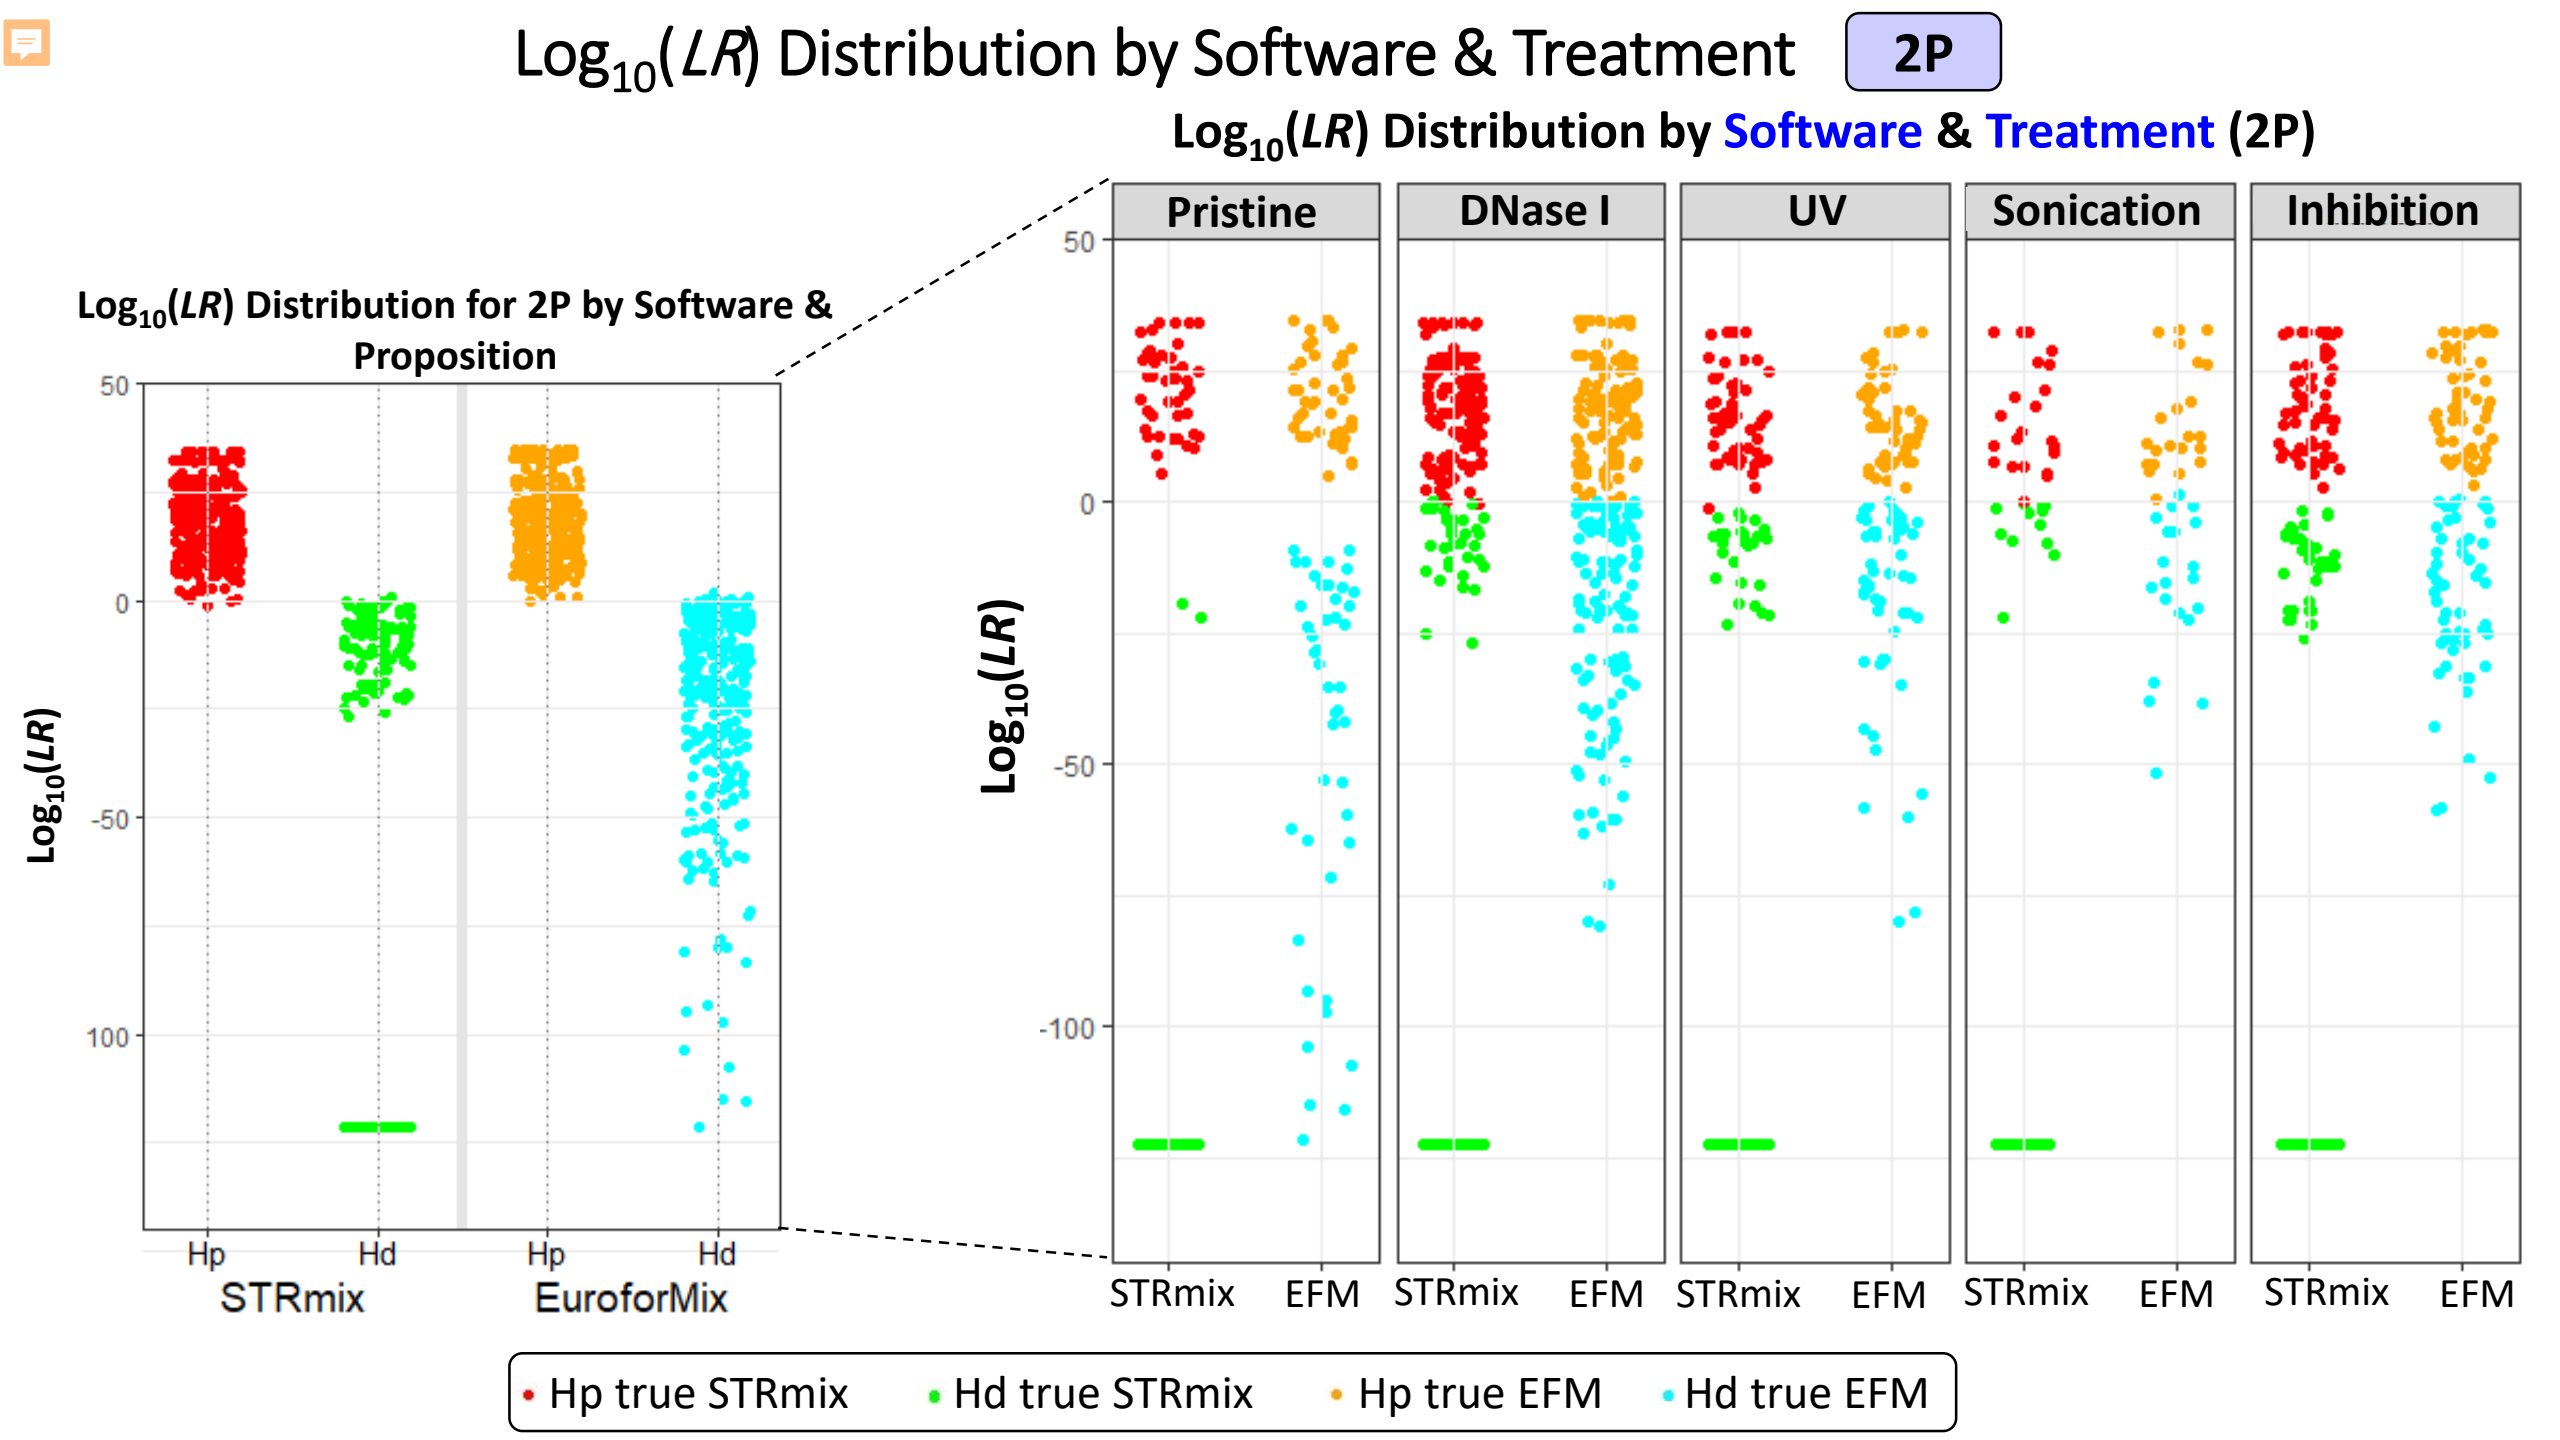


$Log_{10}(LR)$ Distribution by Software & Mixture Ratios **2P**

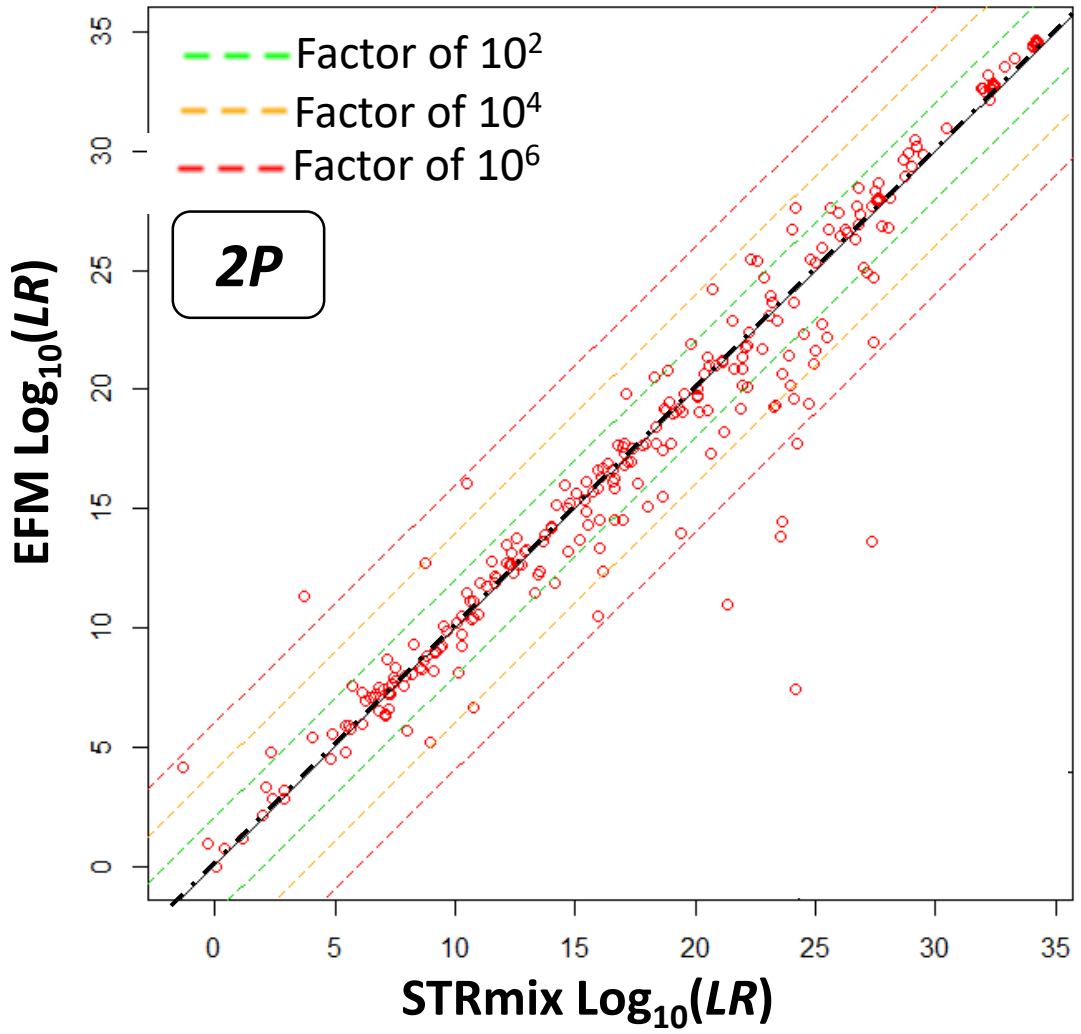


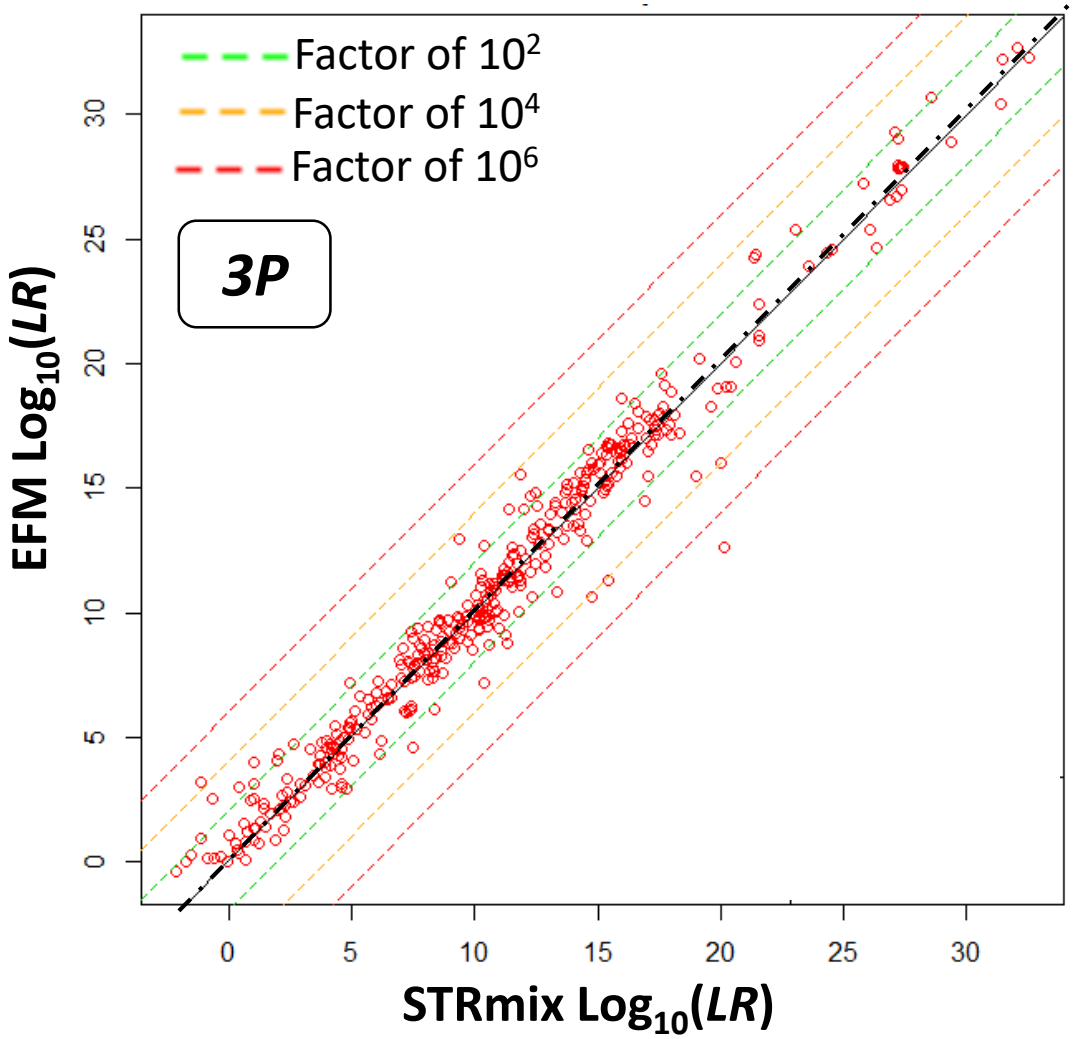


$Log_{10}(LR)$ Distribution by Software & Treatment 2P

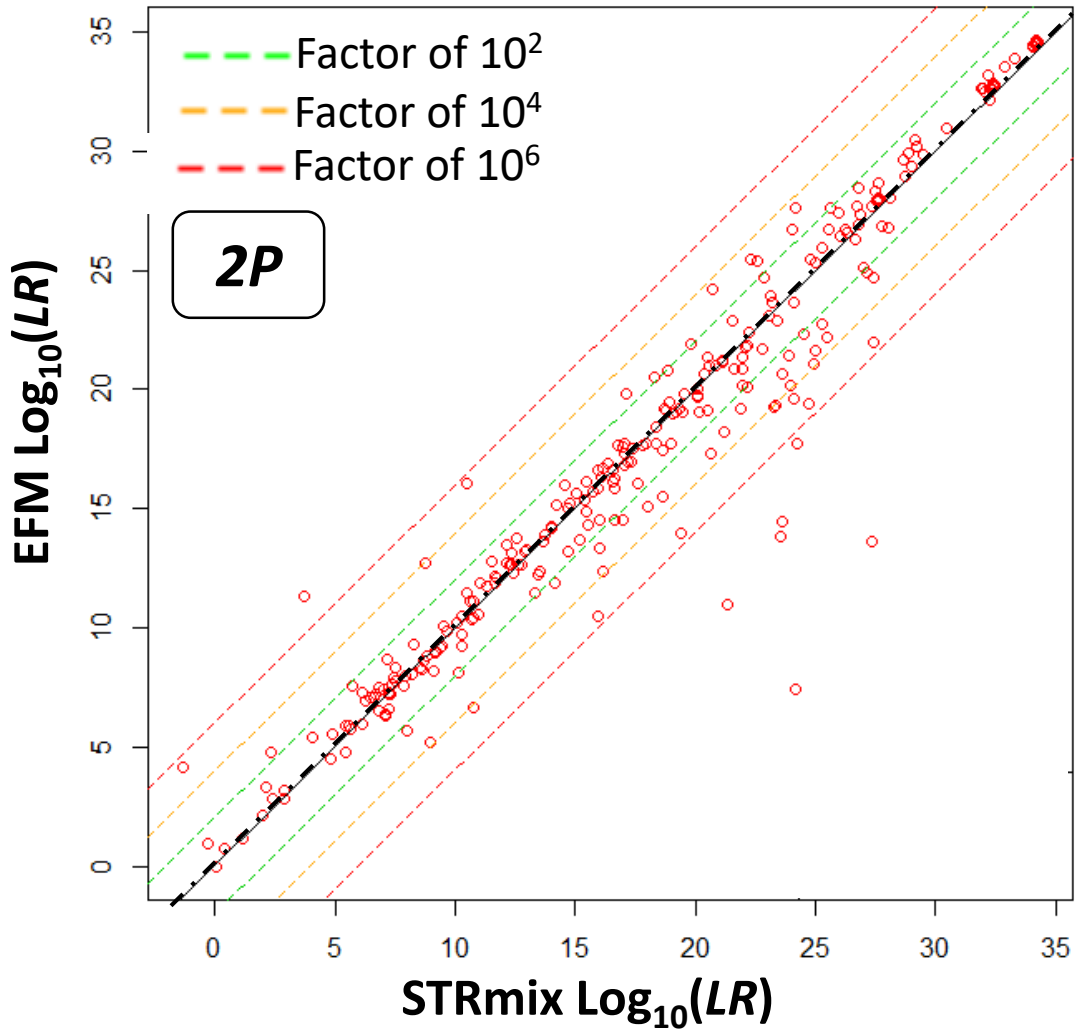


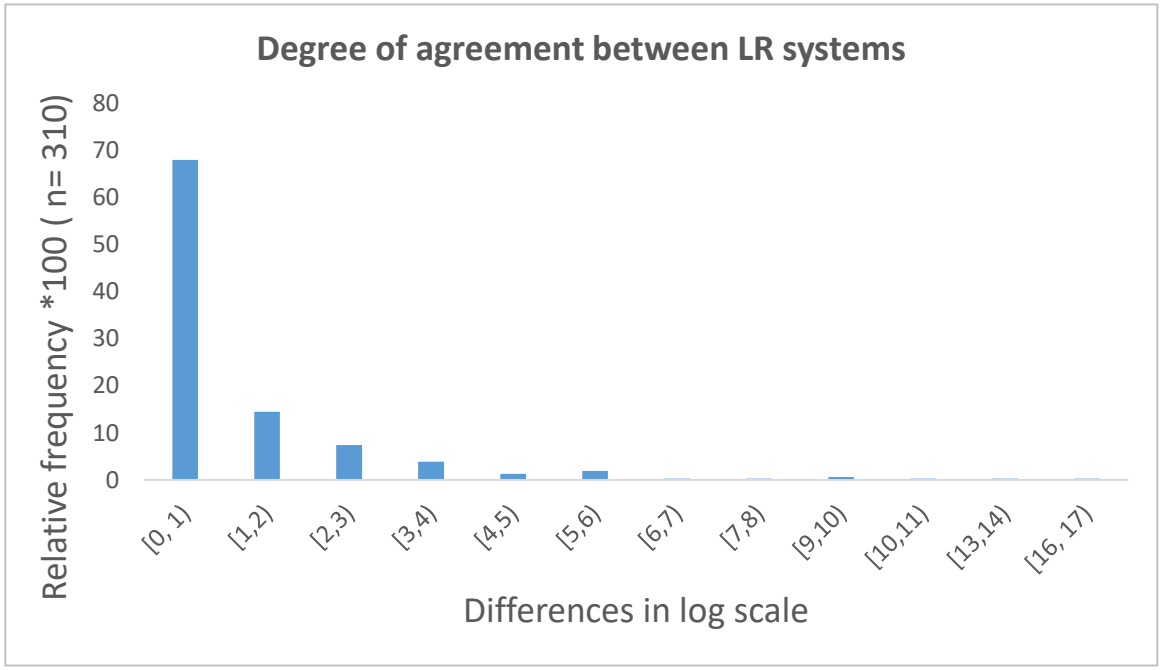
Global profile $Log_{10}(LR)$ from 2P and 3P for Hp true





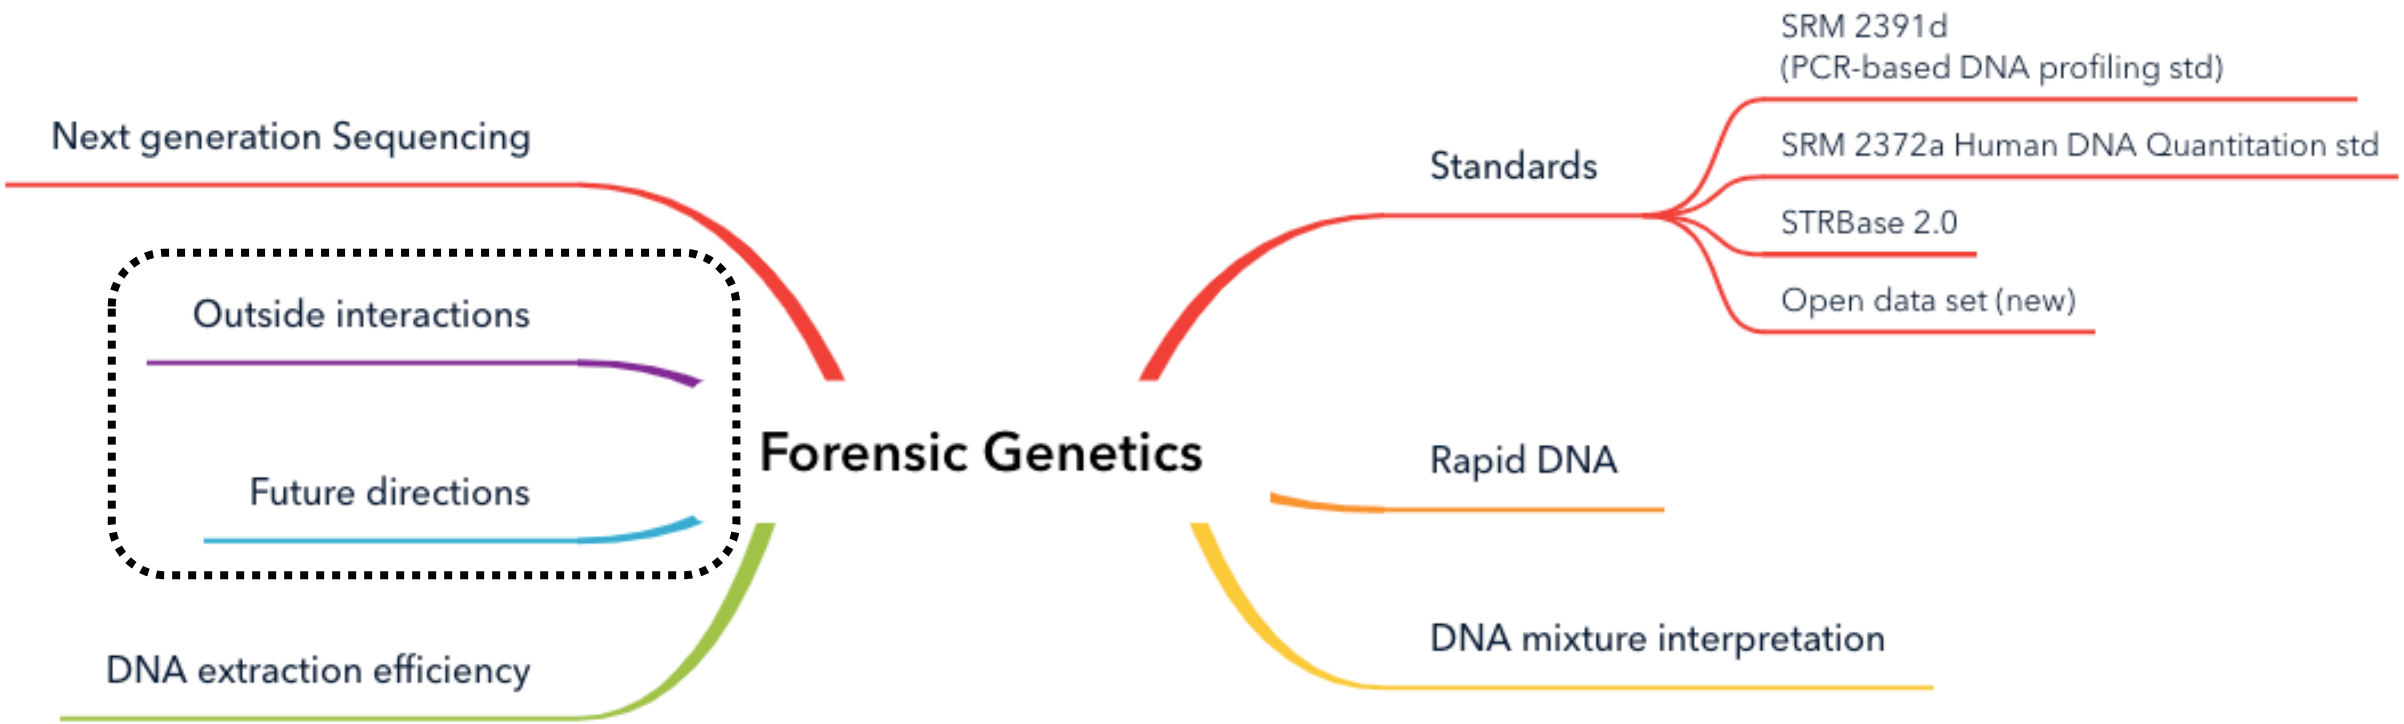
Global profile $Log_{10}(LR)$ from 2P for Hp true





- In the process of finalizing 4-person mixtures
- Investigating the sources of variation
- 155 two-person mixtures
- 147 three-person mixtures
- 132 four-person mixtures

Topics for today



Working group and stakeholder engagement

- NIST: Human Factors and Mixture Review
- NIJ FLNTWG – Sequencing white paper
- NIJ Technology Working Group
- FBI: SWGDAM
  - Laboratory Operations, Sequencing, Body Fluid Identification
- FBI: Rapid DNA task groups
- ISFG: STR Nomenclature (Recommendations)

Research Article

Sequence-based US population data for the SE33 locus

A set of 1036 U.S. Population Samples were sequenced using the Illumina ForenSeq DNA Signature Prep Kit. This sample set has been highly characterized using a variety of marker systems for human identification. The FASTQ files obtained from a ForenSeq DNA Signature Prep Kit experiment include several STR loci that are not reported in the associated software. These include SE33, DXS8377, DXS10148, DYS456, and DYS461.

Description

This information and data are supplemental files associated with: K.B. Gettings, L.A. Borsuk, C.R. Steffen, K.M. Kiesler, P.M. Vallone, Sequence-based U.S. population data for 27 autosomal STR loci, Forensic Science International: Genetics 37 (2018) 106-115. The primary data consists of sequence-based allele frequencies for N=1036 anonymized U.S. population samples at 27 autosomal Short Tandem Repeat (auSTR) loci: D1S1656, TPOX, D2S441, D2S1338, D3S1358, D4S2408, FGA, D5S818, CSF1PO, D6S1043, D7S820, D8S1179, D9S1122, D10S1248, TH01, vWA, D12S391, D13S317, Penta E, D16S539, D17S1301, D18S51, D19S433, D20S482, D21S11, Penta D, and D22S1045. This information is expected to support the implementation of sequence-based STR analysis in forensic applications. /"NIST1036_auSTR_Seq_SuppTables.xls/" is an excel file containing the following worksheets: run metrics for the 42 sequencing runs performed to generate the allele frequency data (S1 - Run Metrics); coverage per locus per sample for all N=1036 at the 27auSTR, 7XSTR, and 24 YSTR loci reported by the manufacturer in this assay (S2 - Coverage); allele frequency data (S3 - Frequencies); GRCh38 reference coordinates for genomic regions reported in the 27 auSTRs (S4 - Ref Coordinates); summary of polymorphisms detected and reported in STR flanking regions (S5 - Flank Polymorph); number of alleles, expected and observed heterozygosity, and p-values associated with HWE testing by population for the 27 auSTR loci (S6 - Hexp_Hobs_pHW); p-values associated with testing for linkage disequilibrium (S7 - LD p-values); and pairwise Fst values by population for the 27 auSTR loci (Supp Table 8 - Pairwise Fst). Lastly, /"NIST1036_auSTR_Seq_SuppFile1.pdf/" contains information on optimization, sequencing, and quality control of the data.

check for updates

Abstract: A total of 1327 platinum-quality mitochondrial DNA haplotypes from United States (U.S.) populations were generated using a robust, semi-automated next-generation sequencing (NGS) workflow with rigorous quality control (QC). The laboratory workflow involved long-range PCR to minimize the co-amplification of nuclear mitochondrial DNA segments (NUMTs), PCR-free library preparation to reduce amplification bias, and high-coverage Illumina MiSeq sequencing to produce an average per-sample read depth of 1000 × for low-frequency (5%) variant detection. Point heteroplasmies below 10% frequency were confirmed through replicate amplification, and length heteroplasmy was quantitatively assessed using a custom read count analysis tool. Data analysis involved a redundant, dual-analyst review to minimize errors in haplotype reporting with additional QC checks performed by EMPOP. Applying these methods, eight sample sets were processed from five U.S. metapopulations (African American, Caucasian, Hispanic, Asian American, and Native American) corresponding to self-reported identity at the time of sample collection. Population analyses (e.g., haplotype frequencies, random match probabilities, and genetic distance estimates) were performed to evaluate the eight datasets, with over 95% of haplotypes unique per dataset. The platinum-quality mitogenome haplotypes presented in this study will enable forensic statistical calculations and thereby support the usage of mitogenome sequencing in forensic laboratories.

Keywords: mtDNA; mitogenome; next-generation sequencing; haplotype; haplogroup; population statistics

Project Aims

Generate high-quality data

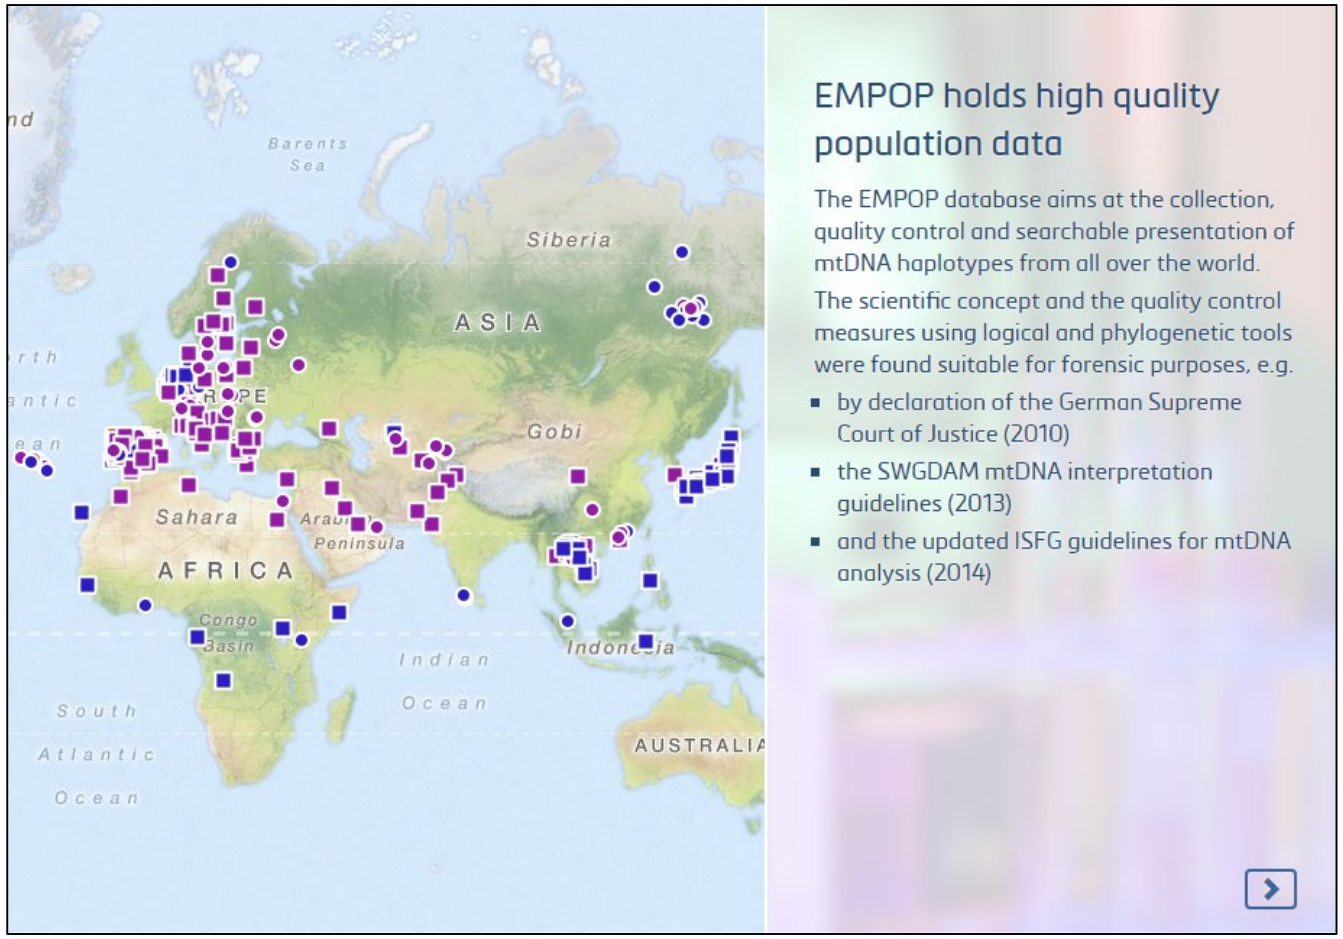
- CLC Bio Genomics Workbench Plugin
  - “AQME” developed by AFDIL
- Double review of variant calls
- Confirmation of heteroplasmy < 10 %

Phylogenetic QC by EMPOP

- International mtDNA database
- Identify unlikely variants

Large dataset of mtGenomes

- 1,327 total passed QC
- Searchable in EMPOP
- Enable match statistics (mtGenome)



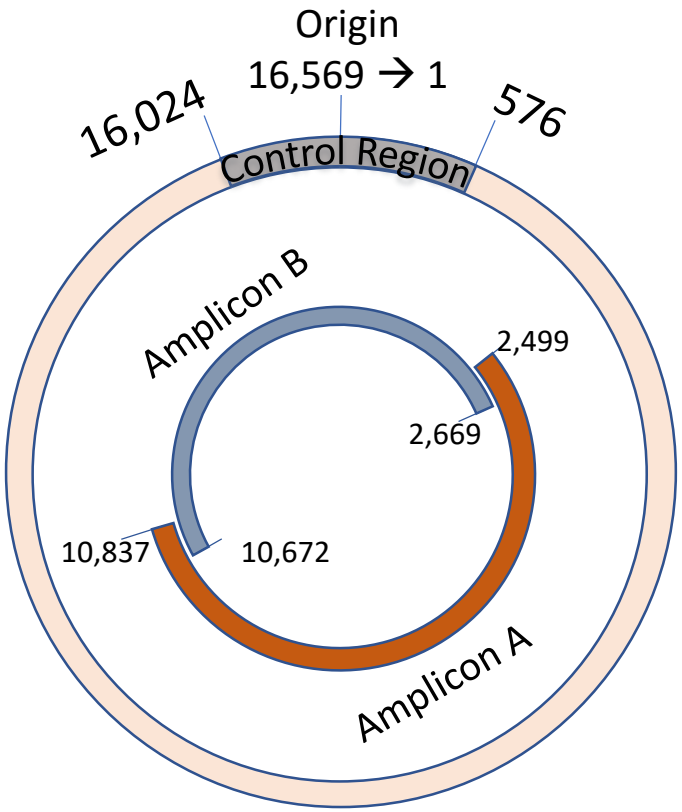
Long-PCR Workflow

PCR
- Two long amplicons ~ 8.5 kb each
- QC +/- on AATI Fragment Analyzer

Library Preparation
- Fragmentation (enzymatic) of PCR products
- Ligate adaptors/barcodes

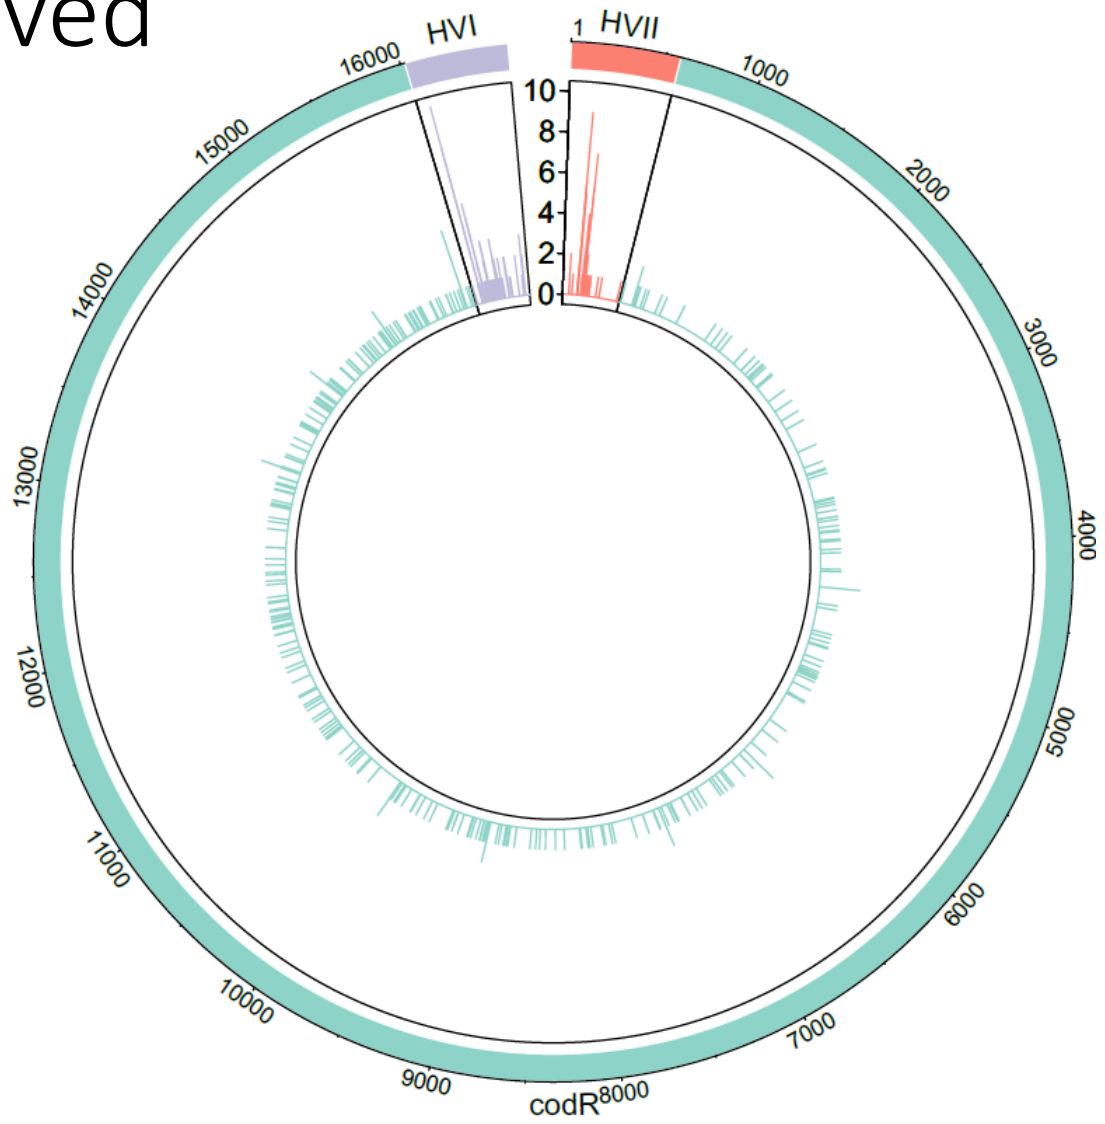
Sequencing
- QC & Quantitate libraries on AATI F/A
- Run on MiSeq FGx

Data Analysis
- Align to reference genome (rCRS)
- Dual Review QC of data



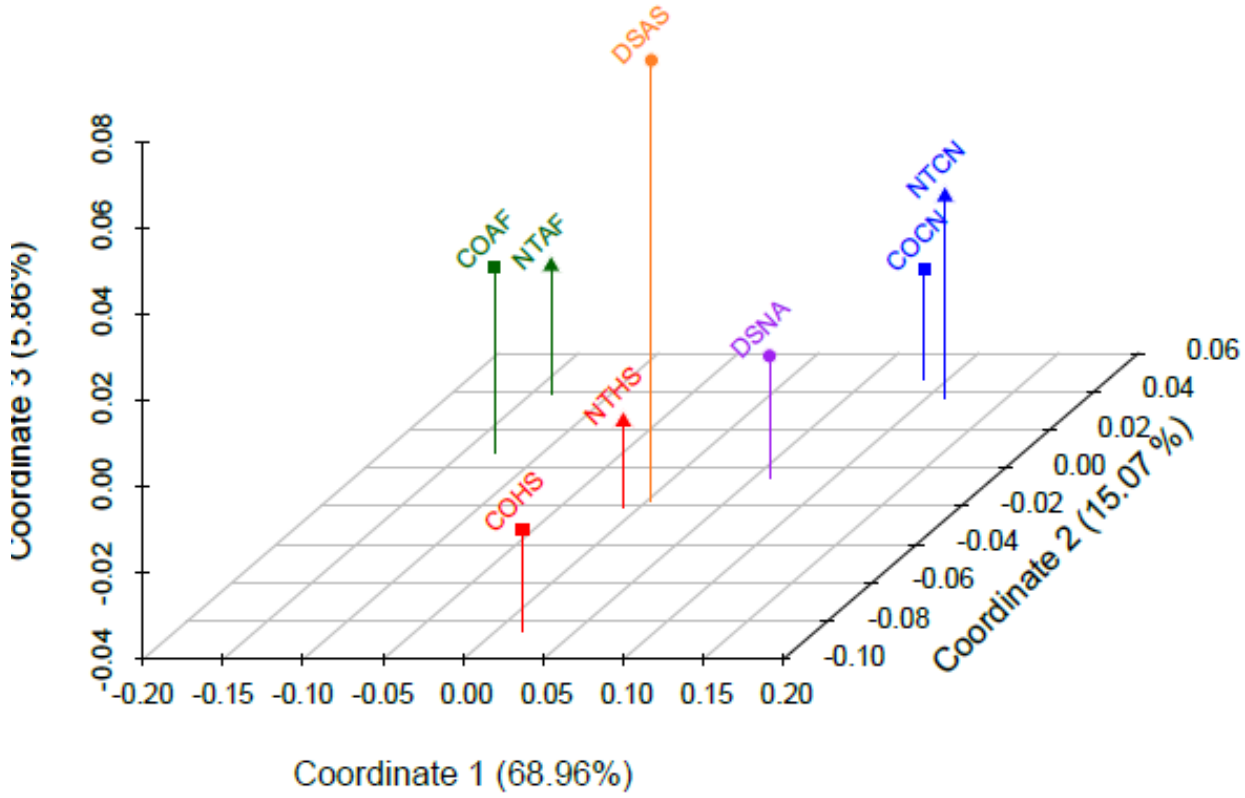
Heteroplasmy Observed

Dataset	Total Individuals	Total PHPs	Individuals with PHPs	Individuals with 1 PHP	Individuals with 2 PHPs	Individuals with 3 PHPs
COAF	112	37	31 (28 %)	26	4	1
COCN	112	41	30 (27 %)	20	9	1
COHS	109	36	27 (25 %)	20	5	2
NTAF	256	77	60 (23 %)	43	17	0
NTCN	260	92	77 (30 %)	65	10	2
NTHS	138	53	43 (31 %)	34	8	1
DSAS	169	62	54 (32 %)	49	2	3
DSNA	171	48	43 (25 %)	38	5	0
All	1327	446	365 (28 %)	295	60	10

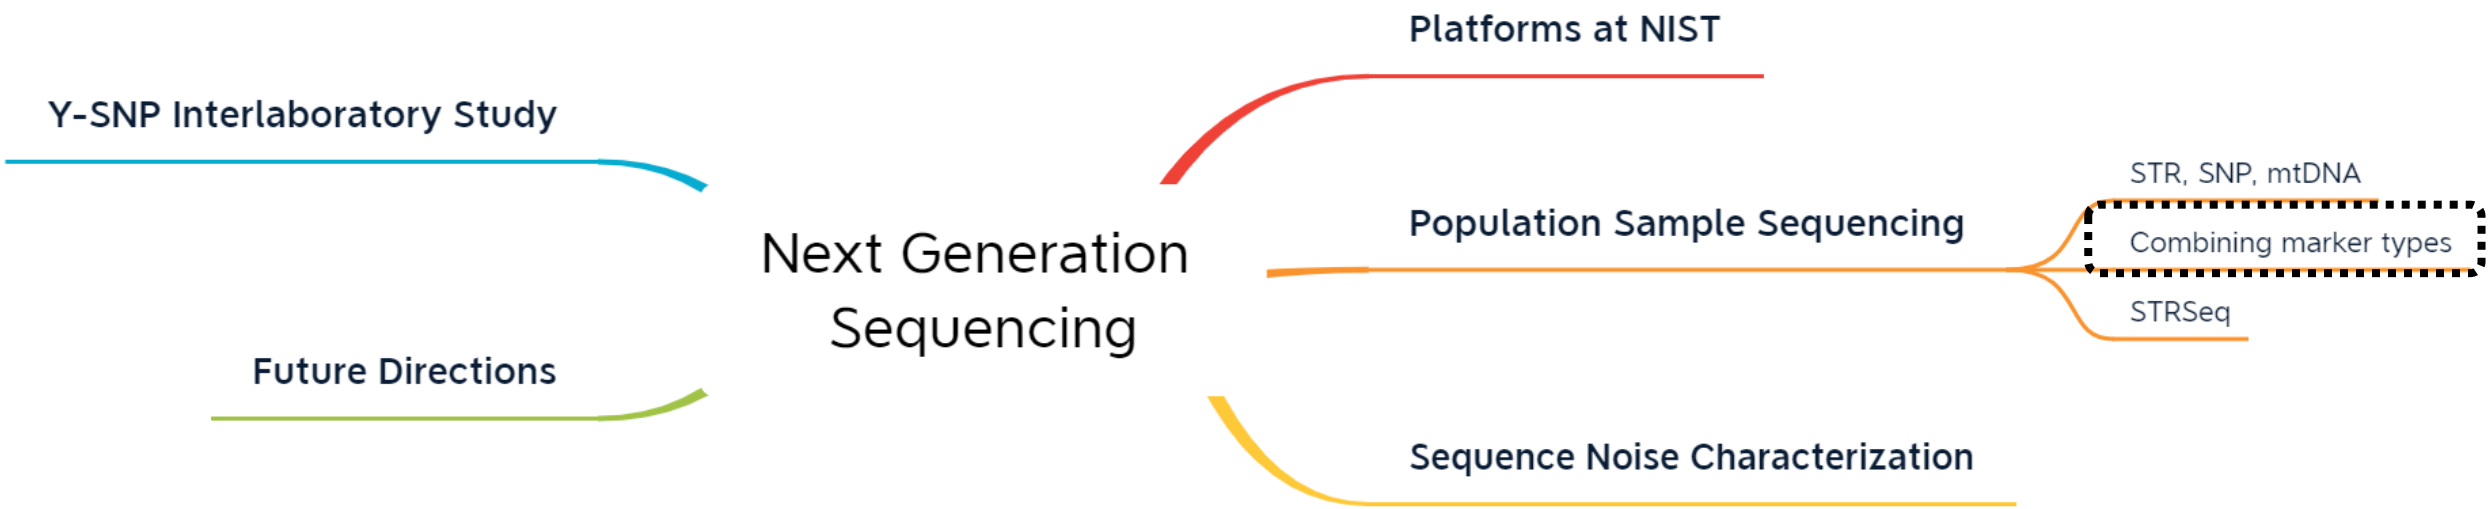


Population Pairwise F_{st} Comparisons

- Similar population ‘samplings’
  - African American and U.S. Caucasian
  - Homogeneous across geographic samples
- Differences in U.S. Hispanics
  - Could be due to site of collection
  - Western U.S. vs Eastern



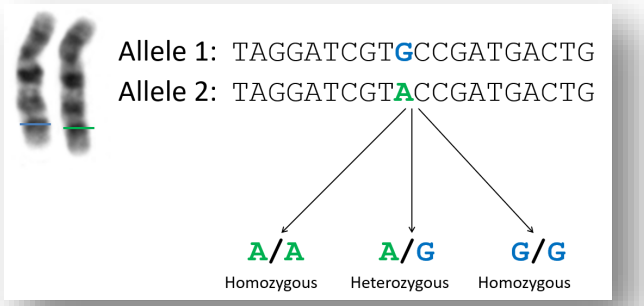
Topics for today



Combining Marker Types

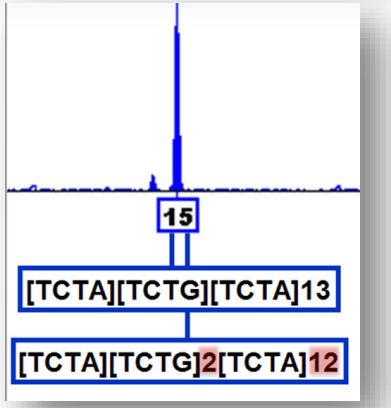
We calculate Match Statistics by multiplying allele frequencies across markers

- Requires markers to be independent



Sequencing allows typing more markers and different marker types

Laboratories need guidance on calculating the appropriate match statistics



Evaluating Linkage Disequilibrium in auSTR and IISNP loci in NIST 1036

Research Article

A multiplex assay with 52 single nucleotide polymorphisms for human identification

A total of 52 SNPs reported to be polymorphic in European, Asian and African populations were selected. Of these, 42 were from the distal regions of each autosome (except chromosome 19). Nearly all selected SNPs were located at least 100 kb distant from known genes and commonly used STRs. We established a highly sensitive and reproducible SNP-typing method with amplification of all 52 DNA fragments in one PCR reaction followed by detection of the SNPs with two single base extension reactions analysed using CE. The amplicons ranged from 59 to 115 bp in length. Complete SNP profiles were obtained from 500 pg DNA. The 52 loci were efficiently amplified from degraded samples where previously only partial STR profiles had been obtained. A total of 700 individuals from Denmark, Greenland, Somalia, Turkey, China, Germany, Taiwan, Thailand and Japan were typed, and the allele frequencies estimated. All 52 SNPs were polymorphic in the three major population groups. The mean match probability was at least 5.0×10^{-19} in the populations studied. Typical paternity indices ranged from 336 000 in Asians to 549 000 in Europeans. Details of the 52 SNP loci and population data generated in this work are freely available at http://www.snpforid.org.

1 Introduction

SNPs have a number of characteristics that make them ideal markers for human identification. First, they have lower mutation rates than the STR and VNTR (variable number tandem repeat) loci typically used for relationship analysis in paternity and immigration testing. Second, SNPs can be analysed after PCR amplification of very short DNA-regions surrounding the substitution site, making SNPs preferable for anthropological and crime case investigations where the DNA is often degraded. Third, SNPs can be genotyped with a growing range of high-throughput technologies; an important factor in the implementation of large criminal DNA databases [1, 2]. Finally, SNPs, as binary polymorphisms, are comparatively easy to validate, because precise allele frequency estimates, required for the accurate interpretation of forensic genotyping data, can be obtained by analysing fewer samples compared to those needed for allele frequencies estimates of STRs and VNTRs. Seeking to match the discriminatory power of the 10–15 multiple allele STRs routinely used in forensic investigations, a set of about 50 polymorphic SNP markers are predicted to be required [3, 4]. Furthermore, it has been suggested that 50 unlinked SNP loci with high overall heterozygosity should be sufficient to adjust for population stratification in population-based associations studies [5]. SNPs that are polymorphic in one population may be almost or completely monomorphic in another population [6, 7], while others are known to be polymorphic in all major population groups. Thus, it should be possible to select SNPs that are useful for human identification purposes in the majority of populations, and to supplement these with SNPs

ORIGINAL INVESTIGATION

SNPs for a universal individual identification panel

Andrew J. Pakstis · William C. Speed · Rixun Fang · Fiona C. L. Hyland · Manohar R. Furtado · Judith R. Kidd · Kenneth K. Kidd

Received: 9 September 2009 / Accepted: 13 November 2009 / Published online: 24 November 2009

Abstract An efficient method to uniquely identify every individual would have value in quality control and sample tracking of large collections of cell lines or DNA as is now often the case with whole genome association studies. Such a method would also be useful in forensics. SNPs represent the best markers for such purposes. We have developed a globally applicable resource of 92 SNPs for individual identification (IISNPs) with extremely low probabilities of any two unrelated individuals from anywhere in the world having identical genotypes. The SNPs were identified by screening over 500 likely/candidate SNPs on samples of 44 populations representing the major regions of the world. All 92 IISNPs have an average heterozygosity >0.4 and the F_{st} values are all <0.06 on our 44 populations making these a universally applicable panel irrespective of ethnicity or ancestry. No significant linkage disequilibrium (LD) occurs for all unique pairings of 86 of the 92 IISNPs (median LD = 0.011) in all of the 44 populations. The remaining 6 IISNPs show strong LD in most of the 44 populations for a small subset (7) of the unique pairings in which they occur due to close linkage. 45 of the 86 SNPs are spread across the 22 human autosomes and show very loose or no genetic linkage with each other. These 45 IISNPs constitute an excellent panel for individual identification including paternity testing with associated probabilities of individual genotypes less than 10^{-15}, smaller than achieved with the current panels of forensic markers. This panel also improves on an interim panel of 40 IISNPs previously identified using 40 population samples. The unlinked status of the subset of 45 SNPs we have identified also makes them useful for situations involving close biological relationships. Comparisons with random sets of SNPs illustrate the greater discriminating power, efficiency, and more universal applicability of this IISNP panel to populations around the world. The full set of 86 IISNPs that do not show LD can be used to provide even smaller genotype match probabilities in the range of 10^{-31}–10^{-35} based on the 44 population samples studied.

Introduction

In previous papers (Kidd et al. 2006; Pakstis et al. 2007), we described the rationale and our strategy for developing a panel of SNPs for individual identification (IISNPs) and presented some potentially useful IISNPs. Such a panel would have use in sample tracking in large collections of human DNA samples and in forensics and paternity testing. Others have also addressed the value of such panels in forensics (Inagaki et al. 2004; Lee et al. 2005; Sanchez et al. 2006; Butler et al. 2008; Pakstis et al. 2008). One panel of 52 SNPs has been accepted for forensic use in several European countries (Sanchez et al. 2006; Phillips et al. 2009). An IISNP panel would provide a complementary tool for forensic applications in situations, such as highly degraded DNA (e.g., Fang et al. 2009), in which the standard STR markers of the widely used *CO*mbined *D*NA *I*ndex *S*ystem (CODIS) panel do not perform well. SNPs also offer a potentially cheaper,

45 SNPs are spread across the 22 human autosomes and show very loose or no genetic linkage with each other

LD in casework

When LD is detected, ideally:

- Rule out technical issues by testing on different platforms/assays
- Confirm with multiple sample sets from same population, and multiple test methods

Designing panel/assay: Evaluate LD, eliminate loci as needed based on informativeness

Implementing established panel/assay:

Best – Determine haplotype frequency for pair or block

- for polymorphic loci the sample size would be unfeasible

Alternative – Exclude one of the two markers during validation

- Keep the more informative, similar to assay design

Problematic – Exclude one of the two markers case-by-case

- RMP vs Kinship

The STR Sequencing Project (human) Accession: PRJNA380127 ID: 380127

The purpose of STRSeq is to facilitate the description of sequence-based alleles at the Short Tandem Repeat (STR) loci targeted in human identification assays. This collaborative effort of the international forensic DNA community, which has been endorsed by the executive board of the ISFG (International Society of Forensic Genetics), provides a framework for communication among laboratories. Each record contains: (a) observed sequence of an STR region, (b) annotation of the repeat region ("bracketing") and flanking region polymorphisms, (c) information regarding the sequencing assay and data quality, and (d) backward compatible length-based allelic designation. Data within the umbrella project is organized into locus sub-projects, and can be accessed by browsing, BLAST searching, or ftp download at NCBI. For comments or questions, please contact strseq@nist.gov.

COMMENT     Annotation ('bracketing') of the repeat region is consistent with
            the guidance of the ISFG (International Society of Forensic
            Genetics), PMID: 26844919.  Lower case letters in the 'Bracketed
            repeat' region below denote uncounted bases.  The given
            length-based allele value was determined using the designated
            length-based technology.  Variation in the length-based allele
            between individuals or assays can result from indels in flanking
            regions.  The length of reported sequence is dependent on the assay
            (see 'Sequencing technology') and the quality of the flanking
            sequence. This information is provided as part of the STR
            Sequencing Project (STRseq), a collaborative effort of the
            international forensic DNA community.  The purpose of this project
            is to facilitate the description of sequence-based STR alleles.
            Additional resources can be found at strseq.nist.gov.  For
            questions or feedback, please contact strseq@nist.gov.  Allele
            frequency data can be accessed in the strider.online database.

ABSTRACT

This report summarizes topics discussed at the STR sequence nomenclature meeting hosted by the STRAND Working Group in April 2019. Invited attendees for this meeting included researchers known-to-us to be developing STR sequence-based nomenclature schemata, scientific representatives from vendors developing STR sequence bioinformatic methods, DNA intelligence database curators, and academic experts in STR genomics. The goal of this meeting was to provide a forum for individuals developing nomenclature schemata to present and discuss their ideas, encouraging mutual awareness, identification of differences in approaches, opposing aspects, and opportunities for parallelization while some approaches are still under development.

1. Introduction

Since 2016, the *ad hoc* formed STR Sequence Working Group (the authorship of this publication) has been collaborating to harmonize related efforts across our respective laboratories, consisting of: STRidER STR sequence quality control [1], STRSeq catalog of sequences [2], STRait Razor bioinformatic freeware [3], the Forensic STR Sequence Structure Guide [4,5], and large-scale population sample sequencing efforts [6–9] (see [10] for a comprehensive review).

To address the more broadly reaching issue of STR sequence nomenclature, we formalized our group in 2018 as the STRAND Working Group (Short Tandem Repeat: Align, Name, Define). Subsequently, we received the endorsement of the ISFG Executive Board to organize an STR sequence nomenclature meeting, which was held in London on April 11th and 12th, 2019. Invited attendees for this meeting included researchers known-to-us to be developing STR sequence-based nomenclature schemata, scientific representatives from vendors developing STR sequence bioinformatic methods, DNA intelligence database curators, and academic experts in STR genomics. BRINGING FORENSIC Y-CHROMOSOME HAPLOGROUPING TO THE NEXT RESOLUTION LEVEL BY USING TARGETED MASSIVELY PARALLEL SEQUENCING

Arwin Ralf, Mannis van Oven, Diego Montiel González, Peter de Knijff, Kees van der Beek, Sharon Wootton, Robert Lagacé, and Manfred Kayser

Y chromosomal SNPs (Y-SNPs) are powerful DNA markers for investigating deep paternal relationships. In forensics, they are used to identify deep paternal lineages and infer paternal bio-geographic ancestry from the male donor of a samples found at a crime-scene. Based on the technology used, previous forensic Y-SNP tools suffered from the low number of markers limiting forensic applications. Increasing the number of Y-SNPs leads to a higher resolution and generally a higher discriminatory power. To overcome previous limitations, we recently developed an MPS-based Y-SNP tool able to simultaneously analyse 859 Y-SNPs that allow inferring 640 Y haplogroups. However, practical applications also depend on the availability of worldwide population frequency data, which we aim to establish via a multi-center study we announce here.

Methodology Labtool

Genomic DNA input range 0.25 – 10 ng

qPCR library quantification

High level multiplex PCR

Ampliseq library preparation

Forensic Y-SNP analysis beyond SNaPshot: High-resolution Y-chromosomal haplogrouping from low quality and quantity DNA using Ion AmpliSeq and targeted massively parallel sequencing.

Ralf A, van Oven M, Montiel González D, de Knijff P, van der Beek K, Wootton S, Lagacé R, Kayser M.

Call for Worldwide Y-SNP Multicenter Study

To take full advantage of the high-resolution Y haplogrouping ability our MPS tool provides, and thus to increase its practical forensic value, more worldwide reference population frequency data are needed. We invite interested colleagues to participate in a Y-SNP multicenter study that applies our tool to as many as possible worldwide population samples. Results will be published and data will be made publically available.

Sample Requirements

- At least 192 male samples from a single regional population
- Informed consent to use the samples for research purposes
- 1 or more population samples

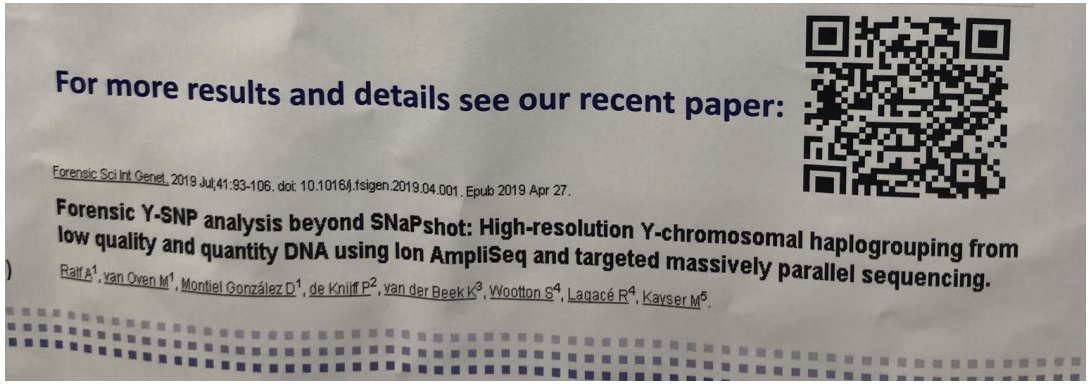
Work Requirements

- Library preparation, quantification and pooling by each participant
- Ion Torrent S5 sequencing by each participant
- Sending library pools to sequencing centers can be arranged

Support Provided

- We will provide an easy protocol and technical support
- Thermo Fisher Scientific agreed on special prices for reagents

To participate, or for more information, contact Arwin Ralf
a.ralf@erasmusmc.nl
with "Y-SNP MCS" as subject



For more results and details see our recent paper:

Reference Paper

Description of Study – Sequencing Y-SNP markers

To obtain worldwide population frequency data:

- 884 Y-SNP Markers sequenced on Ion S5
- Infer 640 Y haplogroups
- ≥192 male samples per population

NIST 1032 male samples:

- 359 U.S. Caucasians
- 341 African Americans
- 236 U.S. Hispanics
- 96 U.S. Asians (extra data as needed)

ABSTRACT

In a worldwide collaborative effort, 19,630 Y-chromosomes were sampled from 129 different populations in 51 countries. These chromosomes were typed for 23 short-tandem repeat (STR) loci (DYS19, DYS389I, DYS389II, DYS390, DYS391, DYS392, DYS393, DYS385ab, DYS437, DYS438, DYS439, DYS448, DYS456, DYS458, DYS635, GATAH4, DYS481, DYS533, DYS549, DYS570, DYS576, and DYS643) and using the PowerPlex Y23 System (PPY23, Promega Corporation, Madison, WI). Locus-specific allelic spectra of these markers were determined and a consistently high level of allelic diversity was observed. A considerable number of null, duplicate and off-ladder alleles were revealed. Standard single-locus and haplotype-based parameters were calculated and compared between subsets of Y-STR markers established for forensic casework. The PPY23 marker set provides substantially stronger discriminatory power than other available kits but at the same time reveals the same general patterns of population structure as other marker sets. A strong correlation was observed between the number of Y-STRs included in a marker set and some of the forensic parameters under study. Interestingly a weak but consistent trend toward smaller genetic distances resulting from larger numbers of markers became apparent.
