

### OOF: Flexible Finite Element Modeling for Materials Science

Andrew Reid, NIST ICME May 24, 2017

### **FEM on Microstructures**

Many years ago, an attempt was made to do FEM modeling of material microstructures.

It proved to be hard, available tools were poorly adapted.

Work began on a materials-focused FEM tool, which evolved to fill this empty niche in the tool space, including image segmentation tools, meshing of microstructures, and extensibility to custom constitutive models.

U.S. Department of Commerce

## **Scope: Materials Science**

- Meso-scale samples (microns)
- Interdisciplinary (chemistry, physics, more)
- Encapsulates math for Materials Science users
- Focused on structure-property relations
  - For a given structure, how do constituent properties control aggregate properties?
  - For given constituents, what structures give good properties?

### **The Math of Materials Science**

For some flux,  $\sigma$  dependent on a field  $\phi$  :

$$M \cdot \ddot{\phi} + C \cdot \dot{\phi} + \nabla \cdot \sigma + f = 0$$

$$\sigma = \sum_{i} \gamma_i \nabla \dot{\phi} + \sum_{i} k_i \nabla \phi$$
Constitutive rule - Materials Science domain experts know this relation

Typical fields: Displacement, temperature, concentration Typical fluxes: Stress, heat flux, chemical flux

### From Math to FE

Continuum equilibrium equation:

 $\nabla \cdot \sigma + f = 0$ 

...becomes, in "weak form"

$$\sum_{i} \int N_j(\vec{x}) \cdot L[N_i(\vec{x})] d\vec{x} \cdot \phi_i + \int N_j(\vec{x}) f(\vec{x}) d\vec{x} = 0$$

National Institute of Standards and Technology U.S. Department of Commerce Use this to put together a highly general, extensible solver, with arbitrary couplings from unknown constitutive rules

- Stack images into a 3D voxel set
- Modify the image blur, despeckle, edge-detect
- Segment selection tools (burn, brush) identify constituent phases
- Overlay a regular, space-filling grid
- Manipulate the mesh to match the segmentation boundaries
  - Bisection, node movement, simulated annealing
  - Tools preserve sanity, space-filling features of the mesh
  - Energy function (homogeneity, shape) measures quality

# The OOF user is an expert in interpreting the results, and can rapidly assess correctness of the steps.

Solve the system – nonlinear, time-dependent, sparse solvers

Local graphics window provides interactive assessment of data PDF export capability, publication-quality Statistical tools – average, standard deviation, min/max Integration of fluxes over boundaries Extensible – new output methods easy to add

National Standard Direct data export capability for more sophisticated analysis U.S. Der OOF developers don't attempt to anticipate all analyses

### **Using OOF**

### GUI mode or Menu-based command mode

>>> ...

# **Architecture**

Written in a combination of Python and C++

### Python and C++:

- Free, multiplatform
- Object-oriented
- Mostly feature-stable

### **Python:**

- Flexible
- Dynamic ("duck typing")
- Many available libraries

SWIG

### C++:

- Many standard tools
- Fast executables
- Even more libraries

## **Automation**

A number of users have successfully used OOF for parametric studies – build a mesh in the GUI, write a command-line script to iterate over a parameter of interest, and perform multiple virtual experiments.

The menu system makes it easy to manipulate OOF objects in Python.

(e.g. K. Hazeli, C. El Mir, S. Papanikolaou, M. Delbo, KT Ramesh, "The Origins of Asteroidal Rock Disaggregation: Interplay of Thermal Fatigue and Microstructure", Icarus, 2017, in press. Arxiv:1701.03510)

# OOF.Material.Assign(material='Chondrule',microstructure='image3.png', pixels='Chondrule') for T in Ts: Pname='T='+str(T).rjust(5,'0') OOF.Mesh.Set\_Field\_Initializer(mesh='image3.png:skeleton:mesh',field=Temperature... OOF.Mesh.Apply\_Field\_Initializers(mesh='image3.png:skeleton:mesh') . . .

# **Automation**

The OOF team is also interested in exploring opportunities for data extraction from online databases, and integration into emerging workflow systems where it might add considerable value.

- Push-button extraction of property data from external databases
  - Materials Project
  - MDCS instances
  - Materials Data Facility?
- Ingestion and generation of standard data formats for existing multiscale or multitool workflows
  - Dream3D, HDF5
  - PRISMS, ICE, others?

### **Development Focus:** Crystal Plasticity

The crystal plasticity problem spans different scientific and engineering communities, and multiple length scales, and would benefit from a materials-focused real-space tool.

- Mechanical properties are fundamental to materials behavior
- Plasticity is fundamental to mechanical properties of metals
- Crystal plasticity couples crystallography to macro behavior
- Path from plasticity to forming traverses many length scales
- Input data comes from many diverse communities

### **Development Focus:** Crystal Plasticity

$$\sigma = \sum_i \gamma_i 
abla \dot{\phi} + \sum_i k_i 
abla \phi_{\rm non-analytic features}^{+ {
m field-dependent and non-analytic features}}$$

Plasticity is not a straightforward PDE, has historydependent info, and inequality constraints

### Approach:

Make contact with plasticity experts from the experimental and computational mechanics community. (NIST NCAL, CMU, Johns Hopkins)

Adopt the best existing models, build from there.

### **Development Focus:** Crystal Plasticity

Having learned this, our challenge is to incorporate these effects while retaining the generality of scope of the original code, **and** allowing for easily-pluggable plastic constitutive rules, packaged for Materials Science expert users.

**Strategy:** Prototype codes to explore the softwarearchitecture issues which arise here.

**Status:** Mostly solved, ready to start hacking on the main OOF code base.

$$L_p = \sum_{\alpha} \dot{\gamma}^{\alpha} (\mathbf{m}^{\alpha} \otimes \mathbf{n}^{\alpha})$$
$$\dot{\gamma}^{\alpha} = f(S_{ij}) \quad L^p \equiv \dot{F}_p F_p^{-1}$$

### **Current Releases**

- Newest 2D: OOF 2.1.13, December 2016
- Newest 3D: OOF 3.0.1, December 2016
- Full first- and second-order time-dependence (since 2.1)
- Sophisticated nonlinear solvers
- EBSD orientation-map capability (2D only, since 2.0)
- Nonlinearity-friendly property extension API
- Sophisticated meshing and image segmentation tools (since 2.0)
- Wide selection of built-in constitutive rules

## In development

- Parallelization
  - Required for large data sets
- History-dependent properties
  - Viscosity, CPFEM
- Inequality constraints
  - Isotropic plasticity
  - Surface interactions

### **The OOF Team**

### **Development:**

Steve Langer, NIST/ITL Andrew Reid, NIST/MML Shahriyar Keshavarz, NIST/Theiss Günay Doğan, NIST/Theiss

David Feraud, NIST/U. Blaise Pascal Lizhong Zhang (NIST/U. Blaise Pascal) Yannick Congo (NIST/U. Blaise Pascal) Valerie Coffman(formerly NIST/ITL, currently Xometry) Rhonald Lua (formerly NIST/PSU, currently Baylor) Edwin García (formerly NIST/PSU, currently Purdue) Seung-III Haan (formerly UMBC, currently Samsung) Andrew Roosen (formerly NIST/MSEL, currently U Delaware)

#### **Testing and feedback:**

Craig Carter, MIT Edwin Fuller, NIST ret'd
