Y. Sohn	193 nm Scatterfield Microscope
J. Qin	Tool Operation and Data Analysis

- **ITRS metrology roadmap shows defect inspection as red, without known solutions in just two years. We are working with the major manufacturers and suppliers to evaluate and develop new techniques to meet these needs.**

- **Need to measure large patterned areas for process control in manufacturing.**

- **There is a fundamental incompatibility between throughput and resolution.**

- **While there are metrology tools that provide adequate resolution, they have either inadequate throughput or no feasible cost basis.**

- **Optical methods offer unparalleled throughput with tremendous sensitivity.   Dense arrayed and irregular features approaching 1/20th the wavelength can be measured.**

- **The arrayed and directional aspects of future device fabrication are well suited to engineered optical fields.**

- **Spatial frequency modulation of the illumination and collection fields can be tailored to enhance optical defect signals.**

- **Further gains can be achieved at shorter wavelengths.**

- **Don't need super-resolution to image each device, but need to image nm scale pattern and particle defects over large areas!**

Overview

- **Scatterfield Optical Microscopy**

- **3-D simulations**

- **Comparisons using die-to-defect metrology**

- **$\lambda = 193$ nm defect detection experiments**

- **Interference-based defect metrology**

- **Future directions**
The Basis for Scatterfield Imaging
The perception of optical metrology limitations:

Beyond the Rayleigh criterion, what are the model-based optical metrology limits?

Airy Discs

Intensity Distributions
- Are we really limited by the wavelength?

Image   Signature

- Edge-based image analysis is not applicable
  - Go beyond standard edge algorithms and use the entire scattered field

# Isolating the Optical Signal of Interest: Angle-resolved Scatterfield Imaging

- When the intensities at each angle are summed, they result in a "blurred" or averaged signal. The valleys and hills in the profiles add to suppress optical image content.
A single measurement using high NA illumination is similar to the sum of measurements of a feature using a low NA and multiple angles.

Intensity

Blue=0.45 NA
Red=0.1 NA

theoretical data

Microns

hypothetical curves

$$\sum_{\theta=-27°}^{27°} I_{plane\,waves}(\theta) = I_{INA=0.45}$$

Initial detection

Continued detection

No noise

RMS noise = 0.5%

RMS noise = 1.25%

RMS noise = 2.0%
No defect detected

Noise causes false positive

- Realistic noise models are a key to evaluating advanced defect detection.
- Sample noise is on the order of the defect signal.

Here we use the scatterfield microscope in a high magnification angle-resolved mode. A spectroscopic version has also been demonstrated.
Source and Collection Optimization for Arrayed Patterns
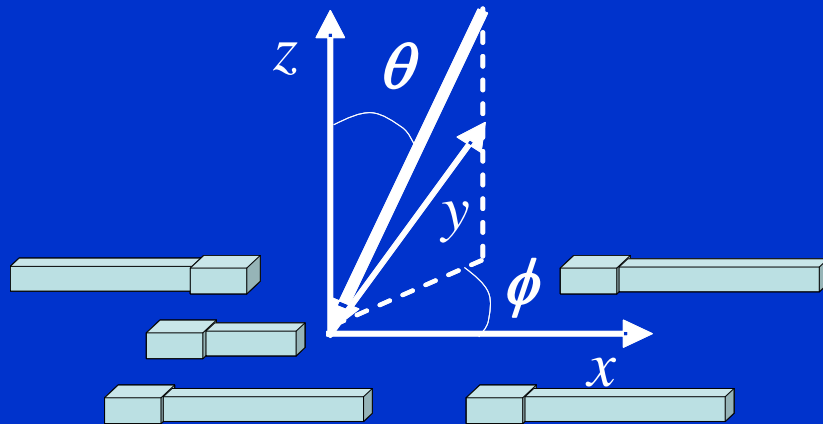

line-to-line
end-to-end

**Optimizing optical defect inspection using:**

- **wavelength**
- **Polarization**
- **spatial frequency**
- **control coherence**
Simulations to Evaluate Trends and Develop the Tools

- **Three-dimensional simulations of structures are performed on defect from the 45 nm to defects below 10 nm.**
  - Finite-difference time-domain (FDTD)
    - Commercially available code
    - In-house code
  - Finite Element Method (FEM)
    - Commercially available code
    - Integral equation solver (in-house)

- **Results are subtracted for die-to-defect comparisons**
No Defect   **With Defect**   **Difference (absolute value)**

High-magnification Platform Modeling Demonstration: Build a Simulation Library

- Parametric analysis:
  - Vary n and k
  - CD (top, mid, and bottom)
  - Height and pitch variation
  - Sidewall variation
  - LER
  - Footing and corner rounding

- Starting point of geometrical variations: AFM reference
  - X3D with full uncertainty analysis

- Several models used in comprehensive simulations
 - 3-Dim FDTD model
  - 3-Dim FEM model
  - 2 & 3-Dim RCWA
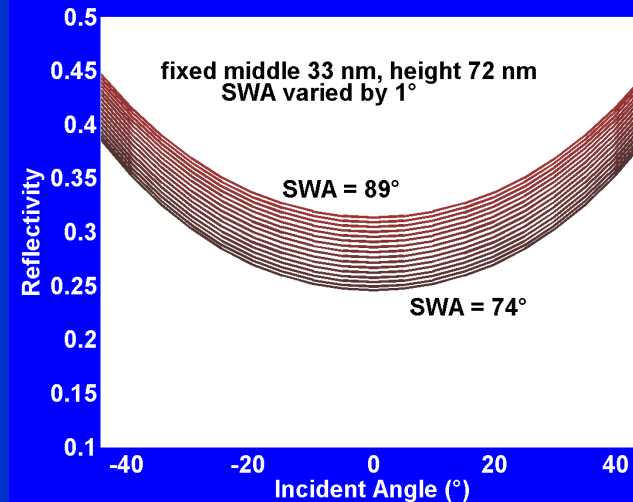

L50/P175
Parallel scan

height:
68 nm to 76 nm
Middle width:
22 nm to 44 nm
SWA:
74 ° to 89°

For more complex stacks, we use fitted reflectivity curves from blanket materials.

# Optical Measurements: Intensity versus Angle Scans

- One or more kernels are placed in an image and the total intensity for each kernel is integrated.

- The intensity is plotted as a function of angle.

- The intensity pattern may include only specular or higher order diffraction components.

- Similar to conventional scatterometry except high magnification imaging optics enable spatial resolution.

Angle-resolved intensity plot.

Full field signal normalization as a function of angle and polarization is required.

Full-field Parallel Scatterometry
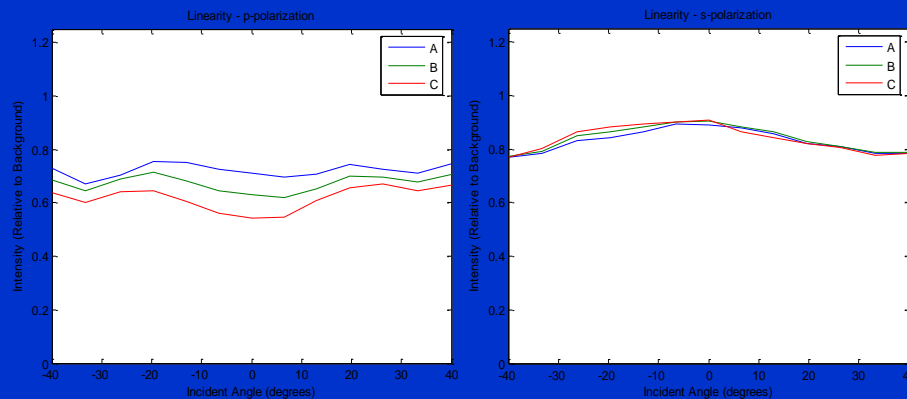

Linearity Target

Sub-arrays nominally 60 nm CD with 5 nm design increments.
**We can perform either single, many parallel scatterometry measurements, or measure very small, embedded targets.**

Gains from Coherent Imaging

- **Introducing coherent illumination has several potential advantages, however this significantly complicates optical design**

Interference Microscopy

Phase angle between the reference beam and the reflected beam is varied from 0 to 360 to improve detectability.

# Interference Microscopy

Simulated interference microscopy difference images have been calculated using the FEM model for 22nm, 30 nm, and 40 nm CD.

30 nm — line-to-line - TE pol. - θ =30 deg., φ =0 deg. - λ = 193 nm - FEM
- **The figure-of-merit is the mean per pixel of the absolute value of the difference image.**

- **The blue line shows the FOM without interference.**

- **The red line shows the shifting of the phase angle.**

Interference Microscopy

**Simulated interference microscopy difference images have been calculated using the FEM model for 22nm, 30 nm, and 40 nm CD.**

30 nm - line-to-line - TE pol. - θ =30 deg., φ =0 deg. - λ = 193 nm - FEM

30 nm – line-to-line

No Interference

Lowest signal @ 150 deg.

Highest signal @ 300 deg.

Interference Microscopy

Interference microscopy using simple reference plane. Difference intensity images simulated using the FEM model for 22nm.

22 nm - end-to-end - TE pol. - θ =0 deg., φ =0 deg. - λ = 193 nm - FEM

22 nm – end-to-end

No Interference

Lowest signal @ 120 deg.

Highest signal @ 330 deg.

Future Directions

- The directional aspects of future arrayed device fabrication are well suited to modulation of illumination and collection optical fields.

- Optical methods offer unparalleled throughput. Want to measure an entire wafer in an hour.

- Results clearly demonstrate gains operating at shorter wavelengths, no single optimum wavelength.

- Pulsed illumination has not been explored.

- Higher NA using immersion microscopy.

- New approaches in holographic/coherent differential imaging.

- Innovative new solutions are required to meet future high throughput defect metrology needs.
