Diffusion through S-boxes

The FLY block cipher
Context

Diffusion through S-boxes

The FLY block cipher
Let’s get started

What do we want? Block ciphers!
- Fundamental primitives in (secret-key) cryptography
- Useful to provide confidentiality and/or authenticity

Where do we want them?
- High-end 64-bit processors
- High-end SoC
- Low-end microcontrollers (8, 16, 32 bits)
- (Small) hardware
AES is good!

- 128-bit blocks, \{128,192,256\}-bit keys
- Fast & versatile
- Good security
- But is AES all what you need?
AES-128 performance on constraint devices

- **Serial** implementation of AES: \( \approx 2400 \text{ GE} \) (Moradi et al., 2011) (226 cyc. per block)

- On 8-bit microcontroller:
  - 146 cpb, \((970 \text{ B ROM} + 18 \text{ RAM})\) (NSA, 2014)
  - 125 cpb \((1912 \text{ B ROM} + 432 \text{ B RAM})\) (Osvik et al., 2010; Osvik, 2014)

- Not bad at all, but can do (slightly better)

- **Lightweight crypto**: try to do better than AES in some specific situations (not easy)
Some lightweight block ciphers (academic)

- **PRESENT-128** (64-bit block, 128-bit key) (Bogdanov et al., 2007)
  - Round-based implementation: 1884 GE (Poschmann, 2009) (Serial: 1391)
  - Not efficient in software

- **PRIDE** (64-bit block, 64-bit key + 64-bit for whitening) (Albrecht et al., 2014)
  - On 8-bit microcontrollers, 189 cpb (266 B ROM)
Some lightweight block ciphers (NSA)

Two members in a big family: SIMON and SPECK (NSA, 2013)

- Many possible block & key sizes
- Efficient both in hardware and software

**SPECK64-128** on 8-bit microcontrollers
  - 154 cpb (218 B ROM) (NSA, 2015)
  - 122 cpb (628 B ROM + 108 B RAM) (NSA, 2015)

**SIMON64-128** on 8-bit microcontrollers
  - 290 cpb (253 B ROM) (NSA, 2015)
  - 221 cpb (436 B ROM + 176 B RAM) (NSA, 2015)
Our goal for today

- Design a block cipher (64-bit blocks, 128-bit keys) with good 8-bit implementation
- Roughly comparable with SPECK/PRIDE/SIMON for efficiency
- With easy arguments v. statistical attacks (like PRIDE)
- With efficient countermeasures v. side-channel attacks (like SIMON)
- Conceptually simple
How to do that

- Use a pure SPN structure (like e.g. PRESENT)
- Combine properties of the S and P layer to count active S-boxes (good for security)
- Use a bitsliced S-box and a "rotation" permutation (good for implementation)
Context

Diffusion through S-boxes

The FLY block cipher
### Branch number of an S-box

The **diff. branch number** of an S-box $S$ is:

$$\min_{\{(a,b)\neq(0,0)\mid \delta_S(a,b)\neq 0\}} \text{wt}(a) + \text{wt}(b)$$

The **lin. branch number** of an S-box $S$ is:

$$\min_{\{(a,b)\neq(0,0)\mid \mathcal{L}_S(a,b)\neq 0\}} \text{wt}(a) + \text{wt}(b)$$

- Reminiscent of the B.N. of a linear mapping ($\approx \min.$ distance of a linear code)
A strategy for pure SPNs (2)

1. Find an S-box with high diff/lin B.N.
2. Find a bit permutation with "good" diffusion
3. Derive a lower bound on # of active S-boxes
Let’s do this: design criteria for an 8-bit S-box

- Diff. & lin. branch number $\geq 3$
- $\text{MDP} \leq 2^{-4}$, linearity $\leq 2^6$ ($\equiv$ linear bias $\leq 2^{-3}$)
- Efficient bitsliced implementation
- Low overall number of operations

Strategy:

- Start from a “nice” 4-bit S-box
- Use a $2 \times 4 \rightarrow 8$ construction (Feistel, Misty, Lai-Massey, ...)

LITTLUN S-box, FLY block cipher
Lai-Massey structure for S-boxes

- Makes 3 calls to the 4-bit S-box with depth 2
- MDP & linearity of the 8-bit S-box \(\approx\) square the one on 4-bit
- 4-bit S-box has Diff. B.N. 3 \(\Rightarrow\) 8-bit S-box has Diff. B.N. 3
- Efficient vector implementations with SSSE3 (not so useful here)

- Condition on Diff. B.N. on 4-bit not necessary
- Lin. B.N. on 8-bit may be 3 (not possible for good 4-bit)
Lai-Massey in a picture

Hi

Lo

$S_4$

$S_4$

$S_4$

$S_4$
How to instantiate the 4-bit S-box?

- Initial strategy: use fastest SERPENT S-box (has B.N. 3) (Biham et al., 1998)
- In the end: use member of Class 13 (Ulrich et al., 2011)
  - Not B.N. 3 but $\Rightarrow$ B.N. 3 on 8-bit anyway
  - Min. # of L. and N.L. gates possible for an optimal 4-bit (4 each)
  - Very efficient bitsliced implementations
\textbf{“LITTLUN-S4” in a picture}

Pierre Karpman
Bitsliced implementation of LITTLUN-S4

\[
\begin{align*}
  t &= b; & b &= a; & b &= c; & // (B): c ^ (a \lor b) \\
  c &= t; & c &= d; & // (C): d ^ (c \& b) \\
  d &= b; & d &= a; & // (D): a ^ (d \& B) \\
  a &= c; & a &= t; & // (A): b ^ (a \lor C)
\end{align*}
\]

- 9 instructions w. 5 registers
Bitsliced implementation of the 8-bit S-box “LITTLUN1”

\[ t = a \oplus e; \]
\[ u = b \oplus f; \]
\[ v = c \oplus g; \]
\[ w = d \oplus h; \]
\[ S4(t, u, v, w); \] // uses one more extra register \( x \)
\[ a \oplus= t; \]
\[ e \oplus= t; \]
\[ b \oplus= u; \]
\[ f \oplus= u; \]
\[ c \oplus= v; \]
\[ g \oplus= v; \]
\[ d \oplus= w; \]
\[ h \oplus= w; \]
\[ S4(a, b, c, d); \] // reuses \( t \) as extra
\[ S4(e, f, g, h); \] // reuses \( u \) as extra

- 43 instructions w. 13 registers
LITTLUN1 meets all the criteria

Only downside: its inverse is more expensive in bitsliced form (59 inst. v. 43)
  - But we know good inverse-free (authenticated) modes of operation (e.g. CLOC, OTR)
Context

Diffusion through S-boxes

The FLY block cipher
A simple design

- 64-bit blocks, 128-bit key
- Round function, optimized for 8-bit microcontrollers:
  1. Apply LITTLUN1 in bitsliced form to $X_0, X_1, \ldots, X_7$ (eight 8-bit words)
  2. Rotate $X_i$ by $i$ to the left
- 20 rounds for the full cipher
- Two key schedules (elementary v. RKA-resistant) (could be improved)
The FLY round function in a picture

$r^k_i$

$S \quad S \quad S \quad S \quad S \quad S \quad S \quad S \quad S \quad S$
Security analysis

- Permutation diffuses “optimally”
- From the B.N. of the S-box ⇒ at least 6 active S-boxes every 4 rounds
- ⇒ at least 18 active S-boxes for 12 rounds ⇒ no single trail with high prob./bias expected
- Other attacks (MiTM, algebraic, integral, impossible diff.) less a concern
Implementation on AVR

- Entire round function + on-the-fly simple key schedule = 76 inst. on ATmega

- 8 more than PRIDE, but with 1.5× more (eqv.) active S-boxes

- $\Rightarrow \approx 200$ cpb., small code (complete perfs. on AVR TBD)

The cost of protection

- Intended implementation target is prone to SCA

⇒ should also consider the cost of countermeasures v. e.g. DPA

- We use the masking compiler of Barthe et al. to obtain masked implementation at various orders (2015)

- Comparison with SIMON/SPECK/PRIDE is favourable
Generate masked implementation, count \#operations to encrypt one block (rough measure)
Conclusion

- LITTLUN1 is a cheap S-box with good diffusion properties
- It is well-suited to a pure SPN design on 64-bit blocks
- FLY is a bitsliced cipher targeting 8-bit microcontrollers
- One of the few bitsliced ciphers with simple security arguments
- Compact and efficient w. or w/o. masking
Fin!
