The rare event problem

Can sample \( \pi \propto e^{-V/\varepsilon} \)

with e.g. Metropolis:

\[
Y^{(t+1)} = X^{(t)} + N(0, \sigma)
\]

\[
X^{(t+1)} = \begin{cases} 
Y^{(t+1)}, & \text{w.p. } 1 \wedge \frac{\pi(Y^{(t+1)})}{\pi(X^{(t)})} \\
X^{(t)}, & \text{otherwise}
\end{cases}
\]

but very slow convergence (exponentially in \( \varepsilon^{-1} \)) for most averages

---

Umbrella Sampling

1. Introduce “bias” functions

\[ \psi_i \geq 0 \quad \sum_i \psi_i = 1 \]

1. Introduce “bias” functions

\[ \psi_i \geq 0 \quad \sum_i \psi_i = 1 \]

2. Define “restrained” distributions

\[ \pi_i \propto \psi_i \pi \]

---

Umbrella Sampling

1. Introduce “bias” functions
   \[ \psi_i \geq 0 \quad \sum_i \psi_i = 1 \]

2. Define “restrained” distributions
   \[ \pi_i \propto \psi_i \pi \]

3. Define normalization constants
   \[ z_i = \int \psi_i(x) \pi(dx) \]

---

Umbrella Sampling

1. Introduce “bias” functions
   \[ \psi_i \geq 0 \quad \sum_i \psi_i = 1 \]

2. Define “restrained” distributions
   \[ \pi_i \propto \psi_i \pi \]

3. Define normalization constants
   \[ z_i = \int \psi_i(x) \pi(dx) \]

4. Assemble general averages
   \[ \int f(x) \pi(dx) = \sum_i z_i \int f(x) \pi_i(dx) \]

Umbrella Sampling

\[ \int f(x) \pi(dx) = \sum_i z_i \int f(x) \pi_i(dx) \]

so

\[ z_j = \int \psi_j(x) \pi(dx) = \sum_i z_i \int \psi_j(x) \pi_i(dx) \]

i.e. the weights \( \{ z_i \} \) solve the **eigenproblem**

\[ z^T = z^T F, \quad \sum_i z_i = 1 \]

with

\[ F_{ij} = \int \psi_j(x) \pi_i(dx) \]

Umbrella Sampling

1. Use your favorite MC scheme to sample from $\pi_i$

2. Estimate the entries of $F$ and each $\int f(x) \pi_i(dx)$

3. Solve the eigenproblem for $\mathcal{Z}$

4. Assemble $\int f(x) \pi(dx) = \sum_i z_i \int f(x) \pi_i(dx)$
A detailed analysis

We establish a central limit theorem with a detailed expression for the asymptotic variance along with a general bound:

\[
\sigma^2(f) \leq 2 \sum_i \frac{1}{\kappa_i} \left\{ \tau_i \bar{z}_i^2 + \pi \|f\|^2 \text{tr}(R^i) \sum_{j \neq i} \frac{\varpi_i(\psi_j)}{P_i[t_j < t_i]} \right\}
\]

\[
R_{jk}^i = \frac{\sigma_{jk}^i}{\sqrt{\varpi_i(\psi_j)} \sqrt{\varpi_i(\psi_k)}}
\]

\(\sigma_{jk}^i\) is the asymptotic covariance of the estimators of \(F_{ij}\) and \(F_{ik}\)

\(P_i[t_j < t_i]\) is the probability that the chain defined by \(F\) and starting from index \(i\) and hitting index \(j\) before returning to \(i\)

An illustrative example

Consider the probability vector:

\[ \pi(i) := \frac{\exp(-LV(i/L))}{\sum_{k=1}^{L} \exp(-LV(k/L))} \]

with \( V(x) = \frac{1}{4\pi} \cos(4\pi x) \)

on the periodic 1D lattice \( \mathbb{Z}/L\mathbb{Z} \)

Nearest neighbor Metropolis MCMC generates a chain with exponentially small spectral gap in \( L \)
An illustrative example

Consider umbrella sampling with
\[ \psi_i(j) = \frac{1}{2}(\delta_i(j) + \delta_{i+1}(j)) \]

Then
\[
F_{ij} = \begin{cases} 
\frac{1}{2} \frac{\pi(i+1)}{\pi(i)+\pi(i+1)}, & j = i + 1 \\
\frac{1}{2} \frac{\pi(i)}{\pi(i)+\pi(i+1)}, & j = i - 1 \\
\frac{1}{2}, & j = i \\
0, & \text{otherwise}
\end{cases}
\]

and
\[ z_i = \frac{1}{2}(\pi(i) + \pi(i + 1)) \]

We can sample
\[ \pi_i(j) = \frac{\pi(i)\delta_i(j) + \pi(i + 1)\delta_{i+1}(j)}{\pi(i) + \pi(i + 1)} \]
e.g. by Metropolis

with simple random walk proposals

An illustrative example

The inequality:

$$\left| \log \frac{\pi(i)}{\pi(i + 1)} \right| = L \left| V \left( \frac{i + 1}{L} \right) - V \left( \frac{i}{L} \right) \right| \leq 1$$

implies that sampling of $\pi_i$ is not hard, i.e.:

$$\text{tr}(R^i) \sim \frac{1}{\text{# of MCMC steps in window } i}$$

and also that

$$F_{i, i \pm 1} = \frac{1}{2} \frac{1}{1 + \exp \left[ \pm L \left( V \left( \frac{i + 1}{L} \right) - V \left( \frac{i}{L} \right) \right) \right]} \geq \frac{1}{2} \frac{1}{1 + e}$$

An illustrative example

And \( P_i[t_j < t_i] \geq F_{ij} \) implies that

\[
\sum_{j \neq i \atop F_{ij} \neq 0} \frac{\text{var}_{\pi_i}(\psi_j)}{P_i[t_j < t_i]} \sim 1
\]

So

\[
\sigma^2(f) \sim \frac{L}{\# \text{ of MCMC steps per window}}
\]

and total cost to achieve fixed accuracy scales about like \( L^2 \)

i.e. not exponentially!

A detailed analysis

US can reduce cost to sample $\pi \propto e^{-V/\varepsilon}$ from exponential in $\varepsilon^{-1}$ to algebraic.

The restrained distributions can be much easier to sample. E.g. if $\psi_i$ is constant on a strip $Z_h$ of width $h$ and if $\pi_i$ is sampled using reflected overdamped Langevin, then

$$\sigma_h^2(f) \leq \frac{\Lambda h^2 \text{var}_h(f)}{\varepsilon} \exp \left( \frac{\max_{Z_h} V - \min_{Z_h} V}{\varepsilon} \right)$$

But: You have to think about how the eigenproblem amplifies errors in $F$

A detailed analysis

US can reduce the cost to compute tail probabilities \( \mathbf{P}[X \geq M] \) from exponential in \( M \) to algebraic.

Instead of trying to estimate the small probability with relative accuracy, US estimates the relatively large entries in \( \mathbf{F} \).

**But:** Again, you have to think about how the eigenproblem amplifies errors in \( \mathbf{F} \).

E. Thiede, B. Van Koten, A. Dinner, and JW, *in preparation*
A key ingredient

We need to understand the error in the $z_i$ resulting from sampling error in a stochastic matrix $F$

$$z^T = z^T F, \quad \sum_i z_i = 1$$

Existing perturbation bounds for Markov matrices blow up as (one over) the spectral gap of $F$

In US applications the spectral gap of is typically extremely small.

A key ingredient

We are far from the first to consider this problem

Some bounds of the form \( \| \tilde{z} - z \| \leq \kappa_i \| F - F \| \) (from Chao and Meyer 2001):

\[
\begin{align*}
\kappa_1 &= \| Z \|_\infty \\
\kappa_2 &= \| A^\# \|_\infty \\
\kappa_3 &= \frac{\max_j (a^\#_{jj} - \min_i a^\#_{ij})}{2} \\
\kappa_4 &= \max_i,j |a^\#_{ij}| \\
\kappa_5 &= \frac{1}{1 - \tau_1(P)} \\
\kappa_6 &= \tau_1(A^\#) = \tau_1(Z) \\
\kappa_7 &= \frac{\min_j \| A^{-1}_{ij} \|_\infty}{2} \\
\kappa_8 &= \frac{1}{2} \max_j \left[ \frac{\max_{i \neq j} m_{ij}}{m_{jj}} \right]
\end{align*}
\]

Existing bounds blow up as the spectral gap decreases

A key ingredient

We establish new more detailed bounds that show that error can be small even when spectral gap is small

If $z^T = z^T F$ and $\tilde{z}^T = \tilde{z}^T \tilde{F}$ with $F_{ij}, \tilde{F}_{ij} \geq S_{ij}$ for some sub-stochastic matrix $S$ then

$$\max_k |\log z_k - \log \tilde{z}_k| \leq \sum_{i \neq j} |\log(F_{ij} + \gamma_{ij}) - \log(\tilde{F}_{ij} + \gamma_{ij})|$$

where

$$\gamma_{ij} = P_i(\tau_j < \min\{\tau_i, \tau\}) - S_{ij}$$

and $\tau_i$ and $\tau$ are respectively the first time to arrive at state $i$ and absorption time for the absorbing Markov process governed by $S$.

A typical US application: A free energy surface for the alanine dipeptide
Joint posterior of cosmological values

\[ \Omega_m : \text{mean dimensionless matter} \]

\[ \Omega_\lambda : \text{vacuum energy density} \]

US with two different choices of bias functions:

(tempering) \[ \pi_i \propto (\pi)^{\alpha_i} \quad \alpha_i \in (0, 1] \]

(collective variable) bias functions restrict along strips parallel with long axis of level sets

In both cases US gives much more accurate representation of the tails of the posterior

In particular we obtain a more accurate estimate of the probability that the expansion of the universe is decelerating, contradicting previous (higher) estimates.

C. Matthews, JW, A. Kravstov, and E. Jennings, in preparation
new applications + improvements for current applications

We estimate expectations of the form:

$$E \left[ \sum_{t=0}^{\tau-1} f(t, X^{(t)}) \right]$$

$\tau$ is a first hitting time for $(t, X^{(t)})$

Associate with $X^{(t)}$ an index process

$$J^{(t)} \in \{0, 1, 2, \ldots, n\}$$

that labels regions in both space and time:

$$J = j$$

---

Illustrative example: Computing set hitting probabilities in the isomerization of the alanine dipeptide

Compute the probability $P_{BA} = \mathbf{P}_x [\tau_B < \min \{ \tau_A, \tau_{\text{max}} \}]$ that the system hits the set $B$ before hitting the set $A$ and before time $\tau_{\text{max}}$
Illustrative example: Computing set hitting probabilities in the isomerization of the alanine dipeptide

\[ \phi^{(0)} = -58.0^\circ \quad P_{BA} \approx \frac{N_B}{N} \quad f(t, X(t)) = 1_B(X(t)) \]

\[ \tau - 1 = \min\{\tau_A, \tau_B, \tau_{\text{max}} - 1\} \]

This probability can be very difficult to estimate when the probability of hitting B is very small.
Illustrative example: Computing set hitting probabilities in the isomerization of the alanine dipeptide

To compute $P_{BA}$ using the non-stationary trajectory stratification, we divide the trajectory space along the phi dihedral and along time:

$$f(t, X^{(t)}) = 1_B(X^{(t)})$$

$$\tau - 1 = \min\{\tau_A, \tau_B, \tau_{\max} - 1\}$$

$$E \left[ \sum_{t=0}^{\tau-1} f(t, X(t)) \right] = \sum_{i=1}^{n} z_i \langle f \rangle_i$$
Repeated direct integration ($10^6$ independent simulations)

NEUS stratification

Average $P_{BA}$

- Direct
- Stratification

$P_{BA}(t)/P_{BA}(T)$

$\phi(0) = 58.0^\circ$
$\phi(0) = 91.0^\circ$
- Direct
Choosing $\phi^{(0)} = -91.0$ close to A makes estimating $P_{BA}$ a hard rare event problem.

**Direct Integration**

**NEUS Stratification**
I’ve developed a set of software tools designed to facilitate rapid prototyping of enhanced sampling algorithms.

**Enhanced Sampling Toolkit**

### Enhanced Sampling Algorithms:
- Allows developers to write algorithms in 100% Python
- Enables rapid prototyping in developer friendly languages
- Enables clean and concise writing of algorithmic code

### MD Engines:
- LAMMPS, OpenMM, CHARMM, GROMACS (potential future implementation)
- Dynamics are executed in widely available and popular MD codes
- Computationally expensive part of the code is still executed in fast MD codes
