(Received 20 April 2005; published 11 October 2005)

We combine a limited number of accurately measured transition frequencies in hydrogen and deuterium, recent quantum electrodynamics (QED) calculations, and, as an essential additional ingredient, a generalized least-squares analysis, to obtain precise and optimal predictions for hydrogen and deuterium transition frequencies. Some of the predicted transition frequencies have relative uncertainties more than an order of magnitude smaller than that of the g factor of the electron, which was previously the most accurate prediction of QED.

In the past decade there have been significant advances in both the measurement and theory of transition frequencies in hydrogen and deuterium. With the advent of frequency-comb metrology, the progress in measurements has accelerated to the extent that the uncertainty in the experimental value of the 1S-2S frequency in hydrogen has decreased by 3 orders of magnitude in about ten years [1]. Many other precision measurements of transitions in hydrogen and deuterium with principal quantum number n up to 12 have been made and are listed in Table I, together with the 1S-2S frequency [1–10]. In addition, precise measurements have been made involving states of hydrogen with n = 27 to 30 [11]. Further advances may be anticipated from a number of groups currently working to improve measurement accuracy [12–15].

On the theoretical side, there has been progress in the accuracy of quantum electrodynamics (QED) calculations which has led to a significant reduction of the uncertainty of both the one-photon [16–20] and two-photon [21–26] contributions. In addition to this progress, the application of the least-squares method described here makes it possible in some cases to predict transition frequencies with a relative uncertainty that is more than an order of magnitude smaller than that of the Rydberg constant, which is 6.6 × 10−12.

It is of interest to have accurate calculations of hydrogen and deuterium transition frequencies for comparison to existing and new experimental values, for both frequency standards applications, and as tests of QED. Also, with sufficiently accurate theory available, it would be possible to consider redefining the SI second in terms of an assigned value of the Rydberg constant. Although this would entail about 3 orders of magnitude improvement in the theory, the recent rate of progress suggests that it may be within reach.

In this Letter, we give theoretical values for a number of transition frequencies that are meant to be best values consistent with currently available experimental and theoretical information. Such calculated values for the transitions in Table I follow from the results of the 2002 CODATA least-squares adjustment of the fundamental constants [27–29], and are listed in that table. Of course, the calculated value of the 1S-2S transition in hydrogen should not be viewed as a theoretical prediction, because the least-squares adjustment determines values of the adjusted constants (variables or unknowns of the adjustment) so that the calculated frequency is essentially equal to the very precise measured value. The number in parentheses with each value is the standard uncertainty (estimated standard deviation) in the last two figures. Hyperfine structure effects are not included in the quoted numbers.

For hydrogen or deuterium transition frequencies not included in the 2002 CODATA adjustment, we proceed as follows. The energy level Ei of state i can be written as a function of the fundamental constants and an additional adjusted constant δi which takes into account the uncertainty in the theory [27,30,31]. For example, for the case in which i is a state of hydrogen, we have

$$E_i = H_i(R_\infty, \alpha, A_i(e), A_i(p), R_p) + \delta_i,$$

where the constants that appear as arguments of the function Hi are listed in Table II. Because the values of the constants in Eq. (1), including δi, result from a least-squares adjustment, they are correlated, particularly those for R∞ and Rp, which have a correlation coefficient of 0.996. The uncertainty of the calculated value for the 1S-2S frequency in hydrogen is increased by a factor of about 500 if such correlations are neglected. The function H1 also depends implicitly on c and the Planck constant h. However, these constants are not displayed as variables, because c is a fixed number, and the frequencies (Ei − Eg)/h are essentially independent of h. Levels in deuterium are given as similar functions with p replaced by d.
The theory included in the function \( H_i \) in Eq. (1) is described in detail in Appendix A of Ref. [27], which provides a review of the relevant calculations. Much of that information is in the form of equations that are valid for any state, with the exception of tables of data that only have entries for the levels included in the 2002 CODATA adjustment [32]. Estimates of the theoretical uncertainties of the function \( H_i \), represented by the constant \( \delta_i \) in Eq. (1), are also given in Appendix A of Ref. [27]. The a priori estimated value of \( \delta_i \) is \( \delta_i \)(th) = 0, because the theoretical expression for the levels includes all known contributions. However, the estimated uncertainty \( u[\delta_i \text{ (th)}] \) is not zero, and there are significant covariances between the various \( \delta \)’s that take into account the expected patterns in the uncertainties. For example, for \( S \) states there are components of uncertainty with the functional form \( C/n^2 \), where \( C \) is a common unknown constant, and there are components of uncertainty common to hydrogen and deuterium levels with the same quantum numbers. The theoretical uncertainties and covariances are included in the least-squares adjustment as input data for the adjusted variables \( \delta_i \).

A generalized least-squares adjustment is formulated here along the lines described in Refs. [28,29]. Symbols that refer to data used in the 2002 CODATA adjustment of the constants are also defined in Ref. [28]. New energy levels \( E_j \) to be determined are added to the adjustment, along with the corresponding theoretical expressions of the form in Eq. (1), and for each added level not among those in Table I, a new adjusted variable \( \delta_j \) is added. The updated column vector of input data \( Q_u \), matrix of their covariances \( V_u \), and column vector of variables \( Z_u \) are written in block form as

\[
Q_u = \left( \begin{array}{c} Q \\ Q_\delta \end{array} \right) ; \quad V_u = \left( \begin{array}{ccc} V & T & 0 \\ T^T & S & 0 \\ 0 & 0 & V_E \end{array} \right) ; \quad Z_u = \left( \begin{array}{c} Z \\ Z_\delta \end{array} \right) ,
\]

where \( Q, V, \) and \( Z \) are the corresponding sets of quantites used in the 2002 CODATA least-squares adjustment, \( Q_\delta \) is the set of theoretical data \( \delta_i \)(th) = 0 for the new variables

The table below shows the 2002 CODATA values of the constants used in the evaluation of the spectrum of hydrogen and deuterium.

<table>
<thead>

The table also shows the Transition frequencies in hydrogen \( \nu_H \) and in deuterium \( \nu_D \) used in the 2002 CODATA least-squares adjustment of the values of the fundamental constants and the calculated values. Hyperfine effects are not included in these values.
\[ \delta_t, Z_\delta \text{ is the new set of adjusted variables } \delta_t, \text{ and } Q_E \text{ is input data for the new energy levels } E_j. \text{ In } V_u, \text{ where } V_{uk} = \text{cov}(Q_{u}^k, Q_{u}^l), S \text{ and } T \text{ are the sets of theoretical covariances involving the new } \delta \text{'s, and } E_v \text{ is the set of covariances of the new energy levels } E_j. \text{ Since the input data for the new levels are unknown, we simply assume that the uncertainties are very large and that there are no correlations among them or with the rest of the input data. This yields the blocks of zeros in } V_u \text{ and results in } V_v \text{ being diagonal.}

The input data and adjusted variables are related by the set of observational equations given by

\[ Q_u = F_u(Z_u); \quad \begin{pmatrix} Q \\ Q_\delta \\ Q_E \end{pmatrix} = \begin{pmatrix} F(Z) \\ Z_\delta \\ E(Z_u) \end{pmatrix}, \tag{3} \]

where the dot over the equal sign indicates that the equation represents the ideal relations between the input data and the adjusted constants which are not simultaneously satisfied, since the set of equations is over-determined. In Eq. (3), \( F \) is the set of functions in the observational equations of the 2002 CODATA adjustment, and \( E \) is the set of expressions for the new energy levels of the form in Eq. (1). The observational equations are linearized by writing the Taylor series

\[ Q_u \approx F_u(Z_u^{(0)}) + A_u(Z_u - Z_u^{(0)}) + \cdots, \tag{4} \]

where \( A_u \) is the matrix of derivatives

\[ A_{u ij} = \frac{\partial F_u(Z_u^{(0)})}{\partial Z_u^{(0)}}, \quad A_u = \begin{pmatrix} A & 0 \\ 0 & I \end{pmatrix}, \tag{5} \]

and neglecting higher-order terms. In Eq. (5), \( A \) is the matrix of derivatives from the 2002 CODATA adjustment, \( I \) is the identity matrix, and \( B \) and \( C \) are derivatives of the new energy levels with respect to the old and new variables, respectively. The truncated expression in Eq. (4) corresponds to

\[ Y_u = A_uX_u, \tag{6} \]

where \( Y_u = Q_u - F_u(Z_u^{(0)}) \) and \( X_u = Z_u - Z_u^{(0)} \).

The update adjustment starts with

\[ Z_u^{(0)} = \begin{pmatrix} \hat{Z} \\ 0 \end{pmatrix}, \tag{7} \]

where \( \hat{Z} \) is the final vector of constants from the 2002 CODATA adjustment and

\[ Y_u = \begin{pmatrix} \hat{Y} \\ Y_\delta \\ Y_E \end{pmatrix} = \begin{pmatrix} Q - F(\hat{Z}) \\ Q_\delta - Z_\delta^{(0)} \\ Q_E - E(Z_u^{(0)}) \end{pmatrix}, \tag{8} \]

where \( \hat{Y} \) is the final value of \( Y \) from the 2002 CODATA adjustment and \( Y_\delta = 0 \). The solution \( \hat{X}_u \) to Eq. (6), the value of \( X_u \) that minimizes \( (Y_u - A_uX_u)^T V_u^{-1}(Y_u - A_uX_u) \), is

\[ \hat{X}_u = G_u A_u^T V_u^{-1} Y_u; \quad G_u = (A_u^T V_u^{-1} A_u)^{-1}. \tag{9} \]

The covariance matrix of the solution \( \hat{X}_u \) is \( G_u \), and its calculation is the key to the update. The Schur-Banachiewicz inverse formula \([33,34]\) applied to the upper-left four blocks of the matrix \( V_u \) in Eq. (2) gives

\[ V_u^{-1} = \begin{pmatrix} V^{-1} + V^{-1}TRT V^{-1} & -V^{-1}TR \\ -RTV^{-1} & R \end{pmatrix}, \tag{10} \]

where \( R = (S - T^T V^{-1} T)^{-1} \). For increasing uncertainties of the unknown input data for the new levels \( E_j \), we have \( V_v^{-1} \rightarrow 0 \), and we work in this limit. A direct calculation from Eqs. (5), (9), and (10), with \( V_v^{-1} = 0 \), yields

\[ G_u^{-1} = \begin{pmatrix} G^{-1} + G^{-1}URU^T G^{-1} & -G^{-1}UR \\ -RU^T G^{-1} & R \end{pmatrix}, \tag{11} \]

where \( G = (A^T V^{-1} A)^{-1} \) is the matrix from the 2002 CODATA adjustment and \( U = GA^T V^{-1} T \). Evidently, Eq. (11) is the Schur-Banachiewicz inverse expression for

\[ G_u = \begin{pmatrix} G & U \end{pmatrix} \begin{pmatrix} U^T & U \end{pmatrix}, \tag{12} \]

provided \( R = (P - U^T G^{-1} U)^{-1} \), that is, if

\[ P = S - T^T V^{-1} T + U^T G^{-1} U = S + DT, \tag{13} \]

where \( D = T^T V^{-1} (AGA^T V^{-1} - I) \). This result for \( G_u \), in terms of \( G \), means that the exact result of the enlarged least-squares adjustment can be obtained from results of the 2002 CODATA least-squares adjustment with a relatively simple calculation. That is, the matrix inversions needed for the enlarged adjustment have effectively been carried out exactly, with the results explicitly expressed in terms of the matrices and vectors of the 2002 CODATA adjustment. In particular,

\[ G_u A_u^T V_u^{-1} = \begin{pmatrix} GA^T V^{-1} & 0 & 0 \\ D & I & 0 \end{pmatrix}, \tag{14} \]

so that

\[ \hat{X}_u = \begin{pmatrix} GA^T V^{-1} & 0 \\ D & 0 \end{pmatrix} \begin{pmatrix} Q - F(\hat{Z}) \\ D[Q - F(\hat{Z})] \end{pmatrix} = \begin{pmatrix} 0 \\ D\hat{Y} \end{pmatrix}, \tag{15} \]

or for the adjusted constants

$$\hat{Z}_u = Z_u^{(0)} + \hat{X}_u = \left( \begin{array} {c} \hat{Z} \\ \hat{D}_u \end{array} \right)$$  \hspace{1cm} (16)

with covariance matrix $\text{cov}(\hat{Z}_u) = G_u$. More importantly, Eqs. (12) and (16) show that both the values and uncertainties of the new levels being calculated are influenced by their covariances with the levels in the 2002 CODATA least-squares adjustment, while the values and uncertainties of the variables from that adjustment are not changed at all. Also, since the only adjusted variables that change in the update appear linearly in Eq. (3), no iteration of the update is needed to reach the final result.

The energy levels and their covariances are thus given by

$$\hat{Q}_E = E(\hat{Z}_u),$$

$$\text{cov}(\hat{Q}_E) = B\hat{G}_u^T + C\hat{U}_u^T \hat{B}^T + B\hat{U}_u^T C + \hat{P}_u,$$  \hspace{1cm} (17)

where the latter result is the lower-right block of the relation $\text{cov}(\hat{Q}_u) = A_u \hat{G}_u A_u^T$. The result from Eq. (17) for a transition frequency $\nu_{lm}$ and its standard uncertainty $u(\nu_{lm})$ for the transition $l \rightarrow m$ is given by

$$h \nu_{lm} = \hat{Q}_{El} - \hat{Q}_{Em},$$

$$h u(\nu_{lm}) = \sqrt{\nu_{lm}^2 - 2 \text{cov}(\hat{Q}_{El}, \hat{Q}_{Em}) + \nu_{lm}^2 (\hat{Q}_{Em})}],$$  \hspace{1cm} (18)

where $u(\hat{Q}_{El}) = \text{cov}(\hat{Q}_{El}, \hat{Q}_{El})$, $i = l, m$.

Examples of calculated transition frequencies in hydrogen and deuterium based on this update, starting from the results of the 2002 CODATA least-squares adjustment, are given in Tables III and IV [35]. The frequencies in Tables III and IV all have relative uncertainties that are smaller than the relative uncertainty of the Rydberg constant, mainly as a result of the correlations between $R_{\infty}, R_p$, and $R_d$. In some cases, these values are nearly 5 orders of magnitude more accurate than the corresponding best previous values [36]. A database that gives the frequency of any transition between levels with $n \leq 200$ based on the calculations described here is maintained on the web site [32].

Helpful conversations with G. W. Stewart are acknowledged by one of the authors (P. J. M.).
