(Received 24 July 2012; accepted 12 September 2012; published online 26 October 2012)

This paper contains new, representative reference equations for the thermal conductivity of benzene. The equations are based in part upon a body of experimental data that have been critically assessed for internal consistency and for agreement with theory whenever possible. In the case of the dilute-gas thermal conductivity, a theoretically based correlation was adopted in order to extend the temperature range of the experimental data. Moreover, in the critical region, the experimentally observed enhancement of the thermal conductivity is well represented by theoretically based equations containing just one adjustable parameter. The correlations are applicable for the temperature range from the triple point to 725 K and pressures up to 500 MPa. The overall uncertainty (considered to be estimates of a combined expanded uncertainty with a coverage factor of two) of the proposed correlation is estimated, for pressures less than 350 MPa and temperatures less than 725 K, to be less than 4.4\%.

Key words: benzene; critical phenomena; thermal conductivity; transport properties.

1. Introduction

In a series of recent papers, new reference correlations for the thermal conductivity of normal and parahydrogen, toluene, and SF$_6$ covering a wide range of conditions of temperature and pressure, were reported. In this paper, the work is extended to the thermal conductivity of benzene. In 1990, the Subcommittee on Transport Properties (now International Association for Transport Properties) of the International Union of Pure and Applied Chemistry published a reference correlation for the thermal conductivity of benzene at atmospheric pressure, covering only the liquid range from 295 to 350 K. The present work extends this range from the triple point to 725 K and pressures up to 500 MPa.

The goal of this work is to critically assess the available literature data, and provide a wide-ranging correlation for the thermal conductivity of benzene that is valid over gas, liquid, and supercritical states, and that incorporates densities provided by the recent equation of state of Thol et al. It should further be noted that, although there are some alternative approaches today for developing such correlations (e.g., neural networks), we preferred to follow a procedure based upon kinetic theory and our previous work, as will be discussed in Secs. 2 and 3.

2. Methodology

The thermal conductivity $\lambda$ is expressed as the sum of three independent contributions, as

$$\lambda(\rho, T) = \lambda_0(T) + \Delta \lambda(\rho, T) + \Delta \lambda_c(\rho, T),$$

where $\rho$ is the density, $T$ is the temperature, and the first term, $\lambda_0(T) = \lambda(0,T)$, is the contribution to the thermal conductivity in the dilute-gas limit, where only two-body molecular interactions occur. The final term, $\Delta \lambda_c(\rho, T)$, the critical enhancement, arises from the long-range density fluctuations that occur in a fluid near its critical point, which contribute to divergence of the thermal conductivity at that point. Finally, the term $\Delta \lambda(\rho, T)$, the residual property, represents the contribution of all other effects to the thermal conductivity of the fluid at elevated densities including many-body collisions, molecular-velocity correlations, and collisional transfer.

The identification of these three separate contributions to the thermal conductivity and to transport properties in general is useful because it is possible, to some extent, to treat both $\lambda_0(T)$ and $\Delta \lambda_c(\rho, T)$ theoretically. In addition, it is possible to derive information about $\lambda_0(T)$ from experiment. In contrast, there is almost no theoretical guidance concerning the residual contribution, $\Delta \lambda(\rho, T)$, so that its evaluation is based entirely on experimentally obtained data.

The analysis described above should be applied to the best available experimental data for the thermal conductivity. Thus, a prerequisite to the analysis is a critical assessment of the experimental data. For this purpose, two categories of experimental data are defined: primary data employed in the development of the correlation, and secondary data used simply for comparison purposes. According to the recommendation adopted by the Subcommittee on Transport Properties (now known as The International Association for Transport Properties) of the International Union of Pure and Applied Chemistry, the primary data are identified by the following criteria:

(i) Measurements must have been made with a primary experimental apparatus, i.e., one for which a complete working equation is available.

(ii) The form of the working equation should be such that sensitivity of the property measured to the principal variables does not magnify the random errors of measurement.

(iii) All principal variables should be measurable to a high degree of precision.

(iv) The published work should include description of purification methods and a guarantee of the purity of the sample.

(v) The data reported must be unsmoothed data. While graphs and fitted equations are useful summaries for the reader, they are not sufficient for standardization purposes.

(vi) The lack of accepted values of the thermal conductivity of standard reference materials implies that only absolute and not relative measurement results can be considered.

(vii) Explicit quantitative estimates of the uncertainty of reported values should be given, taking into account the precision of experimental measurements and possible systematic errors.

(viii) Owing to the desire to produce low-uncertainty reference values, limits must be imposed on the uncertainties of the primary data sets. These limits are determined after critical evaluation of the existing data sets.

These criteria have been successfully employed to establish standard reference values for the viscosity and thermal conductivity of fluids over wide ranges of conditions, with uncertainties in the range of 1%. However, in many cases, such a narrow definition unacceptably limits the range of the data representation. Consequently, within the primary data set, it is also necessary to include results that extend over a wide range of conditions, albeit with a poorer accuracy, provided they are consistent with other more accurate data or with theory. In all cases, the accuracy claimed for the final recommended data must reflect the estimated uncertainty in the primary information.
3. The Correlation

Table 1 summarizes, to the best of our knowledge, the experimental measurements of the thermal conductivity of benzene reported in the literature. Fifty-three sets are included in the table. From these sets, 13 were considered as primary data.

The data of Mensah-Brown and Wakeham, Ramires et al., Charitidou et al., and Li et al. were measured in an absolute transient hot-wire instrument with an uncertainty of 0.5%, and these sets were considered as primary data. The older measurements of Horrocks and McLaughlin, performed in an absolute transient hot-wire instrument, were also included in the primary data set. The measurements of Watanabe and Kato and Kashiwagi et al., performed in a relative way in a transient hot-wire instrument, were also considered as primary data, together with the absolute pulsed hot-wire measurements of Tarzimanov et al. Tong and Tianxiang performed thermal conductivity measurements employing a thermal resistor in a relative way, which were included in the primary data set as they extend to higher pressures, with the exception of their 473 K isotherm which appeared inconsistent with their other measurements. Four more investigators were included in the primary data set: Zaitseva et al. who employed a concentric-cylinder instrument, Akhundov and Kostrovskii and Prostov who employed a hot-wire instrument, and finally Rastorguev and Pugash who employed an absolute hot-filament instrument for measurements at very high pressures.

Figure 1 shows the temperature and pressure range of the primary measurements outlined in Table 1. Temperatures for all data were converted to the ITS-90 temperature scale. The development of the correlation requires densities; recently, Thol et al. reviewed the thermodynamic properties of benzene and developed an accurate, wide-ranging equation of state up to 725 K and 500 MPa – limits that hence also restrict the present thermal conductivity correlation. The approximate uncertainties of the density (at a coverage factor of 2) calculated with this equation are 0.1% below 350 K and 0.2% above 350 K for liquid densities, 1% for saturated vapor densities, 0.1% for densities up to 350 K and 100 MPa, and 0.1–0.5% in density above 350 K. The isobaric and saturated heat capacities are obtained with an uncertainty of 1%. Uncertainties in the critical region are higher for the above properties. We also adopt the values for the critical point and triple point from their equation of state; the critical temperature, \( T_c \), and the critical density, \( \rho_c \), were taken to be equal to 562.02 K and 304.792 kg m\(^{-3}\), respectively. The triple-point temperature is 278.674 K.

3.1. The dilute-gas limit

From the primary measurements shown in Table 1, only three investigators performed measurements near the dilute-gas limit. To increase the number of data sets, four more investigators that performed thermal-conductivity measurements near the dilute-gas limit from the secondary data were also included. As only two of the seven sets extend to over 600 K, a theoretically based scheme was preferred in order to correlate the dilute-gas limit thermal conductivity, \( \lambda_{dg}(T) \), over a wide temperature range. The same scheme was successfully adopted in the case of the dilute-gas limit thermal conductivity correlation of toluene and SF\(_6\). A reasonable estimate of the thermal conductivity, \( \lambda_{dg}(T) \), of a pure dilute gas may be obtained from the viscosity, \( \eta_{dg}(T) \), and ideal-gas heat capacity at constant volume, \( C_{V,0} \), through the modified Eucken correlation.

\[
f_{Eu} = \frac{\lambda_{dg}(T)}{\eta_{dg}(T)} \frac{M}{C_{V,0}} = 1.32 + 1.77 \left( \frac{R}{C_{V,0}} \right).
\] (2)

In the above equation, \( M \) represents the molar mass of benzene (78.1118 g/mol), and \( R \) the universal gas constant (8.314 462 1 J mol\(^{-1}\) K\(^{-1}\)). To employ the above equation, the dilute-gas viscosity and the ideal-gas heat capacity at constant volume are required. The dilute-gas viscosity can be written as a function of the reduced collision integral, \( \Omega(T^*) \), as

\[
\eta_{dg}(T) = \frac{5}{16} \left[ \frac{MRT}{\pi} \right]^{1/2} \frac{1}{\sigma^2 \Omega(T^*)} = 0.0266957 \frac{\sqrt{MT}}{\sigma^2\Omega(T^*)}.
\] (3)

and the ideal-gas heat capacity at constant volume, \( C_{V,0} \), can be obtained from the heat capacity at constant pressure, \( C_{p,0} \) (J mol\(^{-1}\) K\(^{-1}\)), (as \( C_{po} = C_{vo} - R \)), as this is given by

\[
\frac{C_{p,0}}{R} = 3.94645 + \sum_{k=3}^{5} \frac{v_k (u_k / T)^2}{\exp(u_k / T) - 1} \exp(u_k / T) - 1,
\] (5)

where \( v_3 = 7.36374, v_4 = 18.649, v_5 = 4.01834, u_3 = 4116 K, u_4 = 1511 K, \) and \( u_5 = 630 K \). Equations (2)–(5) form a consistent scheme for the calculation of the dilute-limit thermal conductivity. It should be noted that the above equations assume that benzene vapor, although not spherical in shape, behaves like a Lennard-Jones gas, an assumption that has been employed successfully in the prediction and correlation of its viscosity (see, for example, Vogel et al.). Furthermore, the use of fixed numerical values in the modified Eucken correlation, Eq. (2), was preferred to the various more sophisticated theories employing quantities that are not easily accessible such the rotational collision number and the diffusion of the internal energy in the gas. The approximation in Eq. (2) is simpler and at the same time produced very good...

<sup>b</sup>Includes vapor data employed to derive the dilute-gas thermal-conductivity correlation.
results. This has also been successfully employed in a similar correlation for toluene.\(^2\)

In the above scheme, the only unknowns are the Lennard-Jones parameters, \(\sigma\) and \(\varepsilon/k_B\). The seven sets of thermal conductivity measurements in the dilute limit were used to optimize these two parameters. The values thus obtained were \(\sigma = 0.540\) nm and \(\varepsilon/k_B = 412\) K. These values also predict the viscosity values of Vogel \textit{et al.}\(^6\) within 1.8\%. The experimental dilute-limit thermal-conductivity values as well as the values predicted by the scheme of Eqs. (2)–(5) are shown in Fig. 2, while Fig. 3 presents the percentage deviations of the dilute-gas experimental data from the values calculated by this scheme.

It can be seen in Fig. 3 that the calculated values from Eqs. (2)–(5) are more or less within the uncertainty of the measurements of each investigator, with the exception of Vines\(^49\) and Vines and Bennett\(^50\) whose measurements show a maximum deviation of 4.5\% although they both quote 1\% uncertainty. In the same figure, the older polynomial correlation for benzene from the values calculated by Eqs. (2)–(5) by more than 4\% over the temperature range 279 K–725 K (the upper temperature limit imposed by the use of the equation of state of Thol \textit{et al.}\(^5\) in the remaining contributions), and hence Eq. (6) was used for the dilute-gas limit thermal conductivity for the work described in all of the following sections.

3.2. The residual thermal conductivity

The thermal conductivities of pure fluids exhibit an enhancement over a large range of densities and temperatures around the critical point and become infinite at the critical point. This behavior can be described by models that produce a smooth crossover from the singular behavior of the thermal conductivity asymptotically close to the critical point to the residual values far away from the critical point.\(^64\)–\(^66\) The density-dependent terms for thermal conductivity can be grouped according to Eq. (1) as \([\Delta\lambda(\rho,T) + \Delta\lambda(\rho,T)]\). To assess the critical enhancement either theoretically or empirically, we need to evaluate, in addition to the dilute-gas thermal conductivity, the residual thermal-conductivity contribution. The
procedure adopted during this analysis used odrpack (Ref. 67) to fit all the primary data simultaneously to the residual thermal conductivity and the critical enhancement, while maintaining the parameters in Eq. (6) already obtained from the fit of the dilute-gas thermal-conductivity data. The density values employed were obtained by the equation of state of Thol et al.5

The residual thermal conductivity was represented with a polynomial in temperature and density

\[
\Delta \lambda (\rho, T) = \sum_{i=1}^{5} \left( B_{1,i} + B_{2,i}(T/T_c) \right) \left( \rho/\rho_c \right)^i.
\]

(7)

The coefficients \( B_{1,i} \) and \( B_{2,i} \) are shown in Table 2.

### 3.3. The critical enhancement

#### 3.3.1. Simplified crossover model

The theoretically based crossover model proposed by Olchowy and Sengers64–66 is complex and requires solution of a quartic system of equations in terms of complex variables. A simplified crossover model has also been proposed by Olchowy and Sengers.68 The critical enhancement of the thermal conductivity from this simplified model is given by

\[
\Delta \lambda_c = \frac{\rho C_v R_D k_B T}{6 \pi \eta}(\Omega - \Omega_0),
\]

(8)

with

\[
\Omega = \frac{2}{\pi} \left[ \frac{C_v - C_p}{C_p} \arctan(\eta_D \xi) + \frac{C_v}{C_p} \eta_D \xi \right],
\]

(9)

and

\[
\Omega_0 = \frac{2}{\pi} \left[ 1 - \exp \left( \frac{1}{(\eta_D \xi)^{-1} + (\eta_D \xi \rho_c/\rho)^2/3} \right) \right].
\]

(10)

In Eqs. (8)–(10), \( k_B \) is Boltzmann’s constant, \( \eta \) is the viscosity, and \( C_p \) and \( C_v \) are the isobaric and isochoric specific heat obtained from the Thol et al. equation of state. Since a wide-ranging reference correlation for the viscosity of benzene is presently unavailable, we used the generalized method of Chung et al.69 to estimate the correlation. To improve the representation of the viscosity specific to benzene, we fit the parameters in the Chung model (\( \sigma, \epsilon/k_B, \omega, \mu, \alpha, \) and \( \kappa \)) to the data of Assael et al.,70 Vieira dos Santos and Nieto de Castro,71 and Vogel et al.62 to obtain the values 0.5023 nm, 444.37 K, 0.5693, 0.3209, and 0.0642, respectively. The correlation length \( \xi \) is given by

\[
\xi = \xi_0 \left( \frac{\rho_c \rho}{T \bar{\rho}_c} \right)^{1/\gamma} \left[ \frac{1}{\left( \frac{\partial \rho(T, \rho)}{\partial p} \right)_T} \left( \frac{T_{ref}}{T} \right) \right]^{1/\gamma} \left( \frac{T_{ref}}{T} \right) \left( \frac{T_{ref}}{T} \right)
\]

(11)

As already mentioned, the coefficients \( B_{1,i} \) and \( B_{2,i} \) in Eq. (7) and \( \eta_D \) in Eqs. (8)–(11) were fitted with odrpack (Ref. 67) to the primary data for the thermal conductivity of benzene. This crossover model requires the universal constants \( R_D = 1.02, \nu = 0.63, \) and \( \gamma = 1.239, \) and system-dependent parameters \( \Gamma \) and \( \xi_0 \). For this work, we adopted the values \( \Gamma = 0.0569 \) and estimated \( \xi_0 = 2.16 \times 10^{-10} \) m, using the method presented in Ref. 72. The effective wavenumber cutoff \( \eta_D \) was found to be equal to \( 6.2 \times 10^{-10} \) m. The reference temperature \( T_{ref} \), far above the critical temperature where the critical enhancement is negligible, was calculated by \( T_{ref} = (3/2) T_c, \) which for benzene is 843.0 K.

Table 3 summarizes comparisons of the primary data with the correlation. We have defined the percent deviation as

\[
PCTDEV = 100 \left( \lambda_{exp} - \lambda_{fit} \right)/\lambda_{fit},
\]

where \( \lambda_{exp} \) is the experimental value of the thermal conductivity and \( \lambda_{fit} \) is the value calculated from the correlation. Thus, the average absolute percent deviation (AAD) is found with the expression

\[
\text{AAD} = \frac{1}{n} \sum_{i=1}^{n} \left| \frac{\lambda_{exp,i} - \lambda_{fit,i}}{\lambda_{fit,i}} \right|.
\]

And the standard deviation (STDEV) is

\[
\text{STDEV} = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} \left( \frac{\lambda_{exp,i} - \lambda_{fit,i}}{\lambda_{fit,i}} \right)^2}.
\]

Table 3 summarizes comparisons of the primary data with the correlation. We have defined the percent deviation as

\[
PCTDEV = 100 \left( \lambda_{exp} - \lambda_{fit} \right)/\lambda_{fit},
\]

where \( \lambda_{exp} \) is the experimental value of the thermal conductivity and \( \lambda_{fit} \) is the value calculated from the correlation. Thus, the average absolute percent deviation (AAD) is found with the expression

\[
\text{AAD} = \frac{1}{n} \sum_{i=1}^{n} \left| \frac{\lambda_{exp,i} - \lambda_{fit,i}}{\lambda_{fit,i}} \right|.
\]

And the standard deviation (STDEV) is

\[
\text{STDEV} = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} \left( \frac{\lambda_{exp,i} - \lambda_{fit,i}}{\lambda_{fit,i}} \right)^2}.
\]

Figure 4 shows the percentage deviations of all primary thermal-conductivity data from the values calculated by Eqs. (1)–(11) as a function of the density, while Figs. 5 and 6 show the same deviations but as a function of the temperature and pressure. The primary data for benzene listed in Table 1 cover a wide range of conditions and extend to 350 MPa. Based on comparisons with the primary data, we calculate the uncertainty (considered to be estimates of a combined expanded uncertainty with a coverage factor of 2) for pressures less than 500 MPa and temperatures less than 725 K to be less...
than 4.4%. Uncertainties in the critical region are much larger, since the thermal conductivity approaches infinity at the critical point and the properties become very sensitive to small differences in the state variables.

The standard correlation proposed by Assael et al.,4 for the thermal conductivity of benzene along the saturation line covering a temperature range from 290 to 350 K, is also shown in Fig. 5. Its deviations from the present correlation are less than 0.4%, which is considered excellent.

Figures 7 and 8 show the percentage deviations of the secondary data from the values calculated by the proposed scheme. The majority of the deviations are well within 10% of the present correlation.

Finally, Fig. 9 shows a plot of the thermal conductivity of benzene as a function of the temperature for different pressures.

### 3.3.2. Empirical critical enhancement

For applications at state points that are relatively distant from the critical point (at least 10–15 K from the critical temperature), the critical enhancement is adequately represented by the following empirical expression:

\[ \Delta \lambda_c(\rho, T) = \frac{C_1}{C_2 + |\Delta T_c|} \exp\left[-(C_1 \Delta \rho_c)^2\right], \]  

(12)

Fig. 7. Percentage deviations of secondary experimental data of benzene from the values calculated by the present model as a function of density. Watanabe and Kato5,5, Tarzimanov et al.7,7, Ramires et al.10, Akhundov15,15, Charitidou et al.11,11, Kashwagi et al.13,13, Zaiteva et al.14,14, Tong and Tianxiang16,16, Rastorguev and Pugash17,17, Mensah-Brown and Wakeham9,9, Li et al.12,12, Horrocks and McLaughlin18,18, Kostrovskii and Prostov19,19, Reference correlation of Assael et al. (*–*).

Watanabe and Kato5,5, Tarzimanov et al.7,7, Ramires et al.10, Akhundov15,15, Charitidou et al.11,11, Kashwagi et al.13,13, Zaiteva et al.14,14, Tong and Tianxiang16,16, Rastorguev and Pugash17,17, Mensah-Brown and Wakeham9,9, Li et al.12,12, Horrocks and McLaughlin18,18, Kostrovskii and Prostov19,19, Reference correlation of Assael et al. (*–*).

Fig. 6. Percentage deviations of primary experimental data of benzene from the values calculated by the present model as a function of pressure. Watanabe and Kato5,5, Tarzimanov et al.7,7, Ramires et al.10, Akhundov15,15, Charitidou et al.11,11, Kashwagi et al.13,13, Zaiteva et al.14,14, Tong and Tianxiang16,16, Rastorguev and Pugash17,17, Mensah-Brown and Wakeham9,9, Li et al.12,12, Horrocks and McLaughlin18,18, Kostrovskii and Prostov19,19, Reference correlation of Assael et al. (*–*).

where $\Delta T_c = (T/T_c) - 1$ and $\Delta \rho_c = (\rho/\rho_c) - 1$. This equation does not require accurate information on the compressibility, specific heat, and viscosity of benzene in the critical region, as does the theory of Olchowy and Sengers. The coefficients of Eqs. (6) and (7) were fixed, while the coefficients of Eq. (12) were fitted to the primary data. The values obtained were $C_1 = 1.1 \times 10^{-3}$ W m$^{-1}$ K$^{-1}$, $C_2 = 7.0 \times 10^{-2}$, and $C_3 = 1.8$.

Figure 10 shows the percentage deviations between the primary data and the values calculated by Eqs. (6), (7), and (12) as a function of the temperature. By comparing Figs. 5 and 10, it can be seen that employing Eq. (12) results in little deterioration in the representation of the data.

4. Computer-Program Verification

Table 4 is provided to assist the user in computer-program verification. The thermal-conductivity calculations are based on the tabulated temperatures and densities. Note that Eq. (6) was employed for the dilute-gas correlation.

5. Conclusion

New wide-ranging correlations for the thermal conductivity of benzene were developed based on critically evaluated experimental data. The correlations are valid from the triple point to 725 K, and at pressures up to 500 MPa. The correlations are expressed in terms of temperature and density, and the densities were obtained from the equation of state of Thol et al. The overall uncertainty (considered to be estimates of a combined expanded uncertainty with a coverage factor of 2) of the proposed correlation is calculated, for pressures less than 350 MPa and temperatures less than 725 K, to be less than 4.4%.
