## **OSAC Proposed Standard**

# **OSAC 2020-N-0007 Best Practice Recommendations for the Management and Use of Quality Assurance DNA Elimination Databases in Forensic DNA Analysis**

Prepared by  
*Human Forensic Biology Subcommittee*  
Version: 1.2  
March 3, 2021

---

### **Disclaimer:**

This OSAC Proposed Standard was written by the Human Forensic Biology Subcommittee of the Organization of Scientific Area Committees (OSAC) for Forensic Science following a process that includes an [open comment period](#). This Proposed Standard will be submitted to a standards developing organization and is subject to change.

There may be references in an OSAC Proposed Standard to other publications under development by OSAC. The information in the Proposed Standard, and underlying concepts and methodologies, may be used by the forensic-science community before the completion of such companion publications.

Any identification of commercial equipment, instruments, or materials in the Proposed Standard is not a recommendation or endorsement by the U.S. Government and does not imply that the equipment, instruments, or materials are necessarily the best available for the purpose.

## **Foreword**

Monitoring contamination is critical to preserving the integrity of forensic DNA results. As part of an overall quality assurance program, forensic DNA laboratories have a comprehensive approach to monitoring for DNA contamination. The primary component of a laboratory's approach to detecting possible contamination is the incorporation of quality control samples such as reagent blanks, extraction controls, and amplification controls. These controls are used to monitor for contamination introduced during the DNA testing process, but do not directly assess the presence of contaminants in individual case samples. An elimination database is an additional component that can be used to directly evaluate case samples for possible contamination. Elimination databases are important to avoid providing misleading information to investigators, entering errant DNA profiles into CODIS, or, more broadly, to detect contaminants. It is essential for each laboratory to develop policies regarding the generation, management, and searching of the elimination database. Laboratories should ensure that their practices adhere to and are in compliance with all applicable laws within their jurisdiction.

## Table of Contents

1. Scope
2. Normative References
3. Terms and Definitions
4. Requirements
5. Annex A (informative) Bibliography

### 1 Scope

This document provides best practice recommendations for the collection, storing, searching, and retention of DNA elimination samples and/or profiles in a quality assurance database. This document addresses the use of elimination databases as one component of a comprehensive approach to detect and monitor contamination.

### 2 Normative References

There are no normative references for these best practice recommendations. Annex A, contains informative references.

### 3 Terms and Definitions

**Contamination:** Exogenous DNA or other biological material in a DNA sample, PCR reaction, or item of evidence; the exogenous DNA or biological material could be present before the sample is collected or introduced during collection or testing of the sample.

**Elimination Profile:** A DNA profile from an individual whose access, role, or activities might result in DNA contamination. The term also includes profiles associated with consumables and positive controls.

**Elimination Database:** A searchable collection of elimination profiles.

### 4 Best Practice Recommendations

4.1 The laboratory should maintain and use an elimination database in accordance with the various laws within its jurisdiction.

4.2 The laboratory should have elimination database policies that address the following:

- a) the purpose of the database;
- b) the generation, management, and searching of the database;
- c) personnel who have access to the database;
- d) the evaluation and resolution of candidate matches; and

e) the reporting of positive associations.

4.3 An elimination database should be comprised of profiles from the following categories.

4.3.1 Individuals who have direct contact with the evidence, such as:

- a) Personnel in the forensic biology/DNA unit of the laboratory
- b) Laboratory personnel who may handle and/or examine evidence prior to the transfer of an item to the forensic biology/DNA unit
- c) Investigative or crime scene personnel who collect or handle evidence
- d) Medical examiner's office personnel, sexual assault nurses, and other hospital staff who may come in direct contact with and handle evidence
- e) Laboratory or investigating agency staff who may handle outer evidence packaging
- f) Laboratory custodial staff who may enter the forensic biology/DNA unit

4.3.2 Individuals with more limited contact with the evidence, such as:

- a) Laboratory staff regardless of work unit or access level to the forensic biology/DNA unit
- b) Investigative agency staff who may be present at the crime scene
- c) Visitors, maintenance staff, or vendor staff who may enter the forensic biology/DNA unit

4.3.3 Additional DNA profiles, such as:

- a) Profiles attributed to consumable manufacturing staff
- b) Unattributed contamination profiles
- c) Laboratory positive control profiles

4.4 All individuals providing samples for the elimination database should sign and receive an information sheet that includes at a minimum:

- a) Organization managing the elimination database
- b) Purpose of the elimination database
- c) The extent to which the samples will be used (e.g. will only be used for quality assurance purposes and not for medical research purposes)
- d) Privacy protections
- e) Acknowledgement that associations to their profile will be evaluated and may be reported
- f) The retention policy for the samples, raw data, and the resultant profile

4.5 Samples should be typed using the test kit(s) currently in use.

4.5.1 Before a laboratory changes or adds a new typing kit, samples from individuals who come in direct contact with evidence should be retyped with that kit.

4.5.2 Samples from individuals who do not come in direct contact with evidence need not be retyped unless needed to assess potential contamination events.

NOTE: A change in typing test kit does not preclude maintaining profiles typed with previous typing test kits.

4.6 All samples tested and profiles entered into the elimination database should be designated with a unique identifier.

4.6.1 Profiles from known individuals should not be labeled with personally identifiable information but should be traceable to the individual from whom the sample originates.

4.6.2 For samples originating from outside of the laboratory, the traceability may be maintained by an external entity.

4.7 The laboratory should have written policies regarding the management of the elimination database that address the following:

4.7.1 Access to the samples and data should be controlled and limited to authorized users to maintain confidentiality and prevent accidental or intentional misuse.

The policy should consider differentiating access levels between those individuals who can view the matches and those individuals who can access the traceability to determine the individual who donated the sample. This may be the same individual or different individuals but should be defined in the policy.

4.7.2 The security of all samples and data in the elimination database should be maintained in a manner that protects against accidental loss, destruction, or manipulation/compromise.

4.7.3 The laboratory should have a mechanism to ensure version control of the elimination database.

4.7.4 The retention time for samples and data should be clearly defined in laboratory policy.

It is recommended to retain original samples for the purpose of retesting as new relevant testing methodologies become available. For retention of profiles in the elimination database, consideration should be given to the potential for contamination risk and the expected time period the material handled by individuals will be in the system. It may be reasonable to archive some profiles and make them available for searching only for selected cases (e.g., cold cases, appeals, and post-conviction cases).

4.8 The laboratory should have policies that address the searching parameters and matching criteria for the elimination database.

4.8.1 The policy should describe the categories of profiles (e.g., single source and/or mixture evidentiary profiles, deduced evidentiary profiles, reference profiles) that will be searched against the elimination profiles.

When feasible, it is recommended that all evidentiary profiles deemed interpretable but not associated to a reference profile be searched against the elimination database.

4.8.2 The policy should address the search stringency and match criteria for detecting potential associations, for example, by a minimum statistical threshold, a minimum number of matching loci,

or the discrimination power of the profile being searched. The selection of search stringency and match criteria will be guided by the intended goal of the search.

Search parameters and the extent of the information contained in the results may vary depending upon the level of searching that will be conducted as well as the number of profiles in the database.

For example, one type of search can be designed with a low association threshold to trigger an investigation. This type of search is effective at detecting true contaminants, even when the level of contamination is very low. The benefit is that this approach could be relied upon as a primary means of detecting contamination. Increases in testing sensitivity, however, are paired with decreases in specificity, and the laboratory could expect increased instances of investigating adventitious matches. This would especially be true for complex profiles, very low-level contributors to mixtures, and large elimination databases.

An alternate type of search with a high association threshold would be effective at detecting gross contamination. A laboratory may choose this approach when, for example, the elimination database search is meant to prevent profiles from entering a government database such as CODIS. Benefits of this approach include fewer investigations of adventitious associations, even with larger database sizes. Such an approach could not be used or relied upon to detect lower level contamination.

4.8.3 The elimination database should be searched prior to a laboratory report being issued, and that search should be documented in the case record.

4.9 The laboratory should have the following policies addressing the investigation of possible associations resulting from an elimination database search:

4.9.1 If contamination is a plausible explanation for the association, the laboratory should follow its quality system protocols.

If an association is made to non-laboratory personnel, it is incumbent upon the laboratory to report this information to the applicable agency or consumable manufacturer for potential retraining or process improvement.

4.9.2 For associations in which contamination is not a plausible explanation, it may be necessary to disclose the association for possible investigation by law enforcement.

4.9.3 Laboratory policy should specify how to address situations in which an association remains ambiguous and cannot be resolved as either contamination or adventitious.

4.10 The laboratory should have the following policies for reporting elimination database associations that are not resolved by re-testing:

4.10.1 If an elimination database association is made after a report has been issued, the laboratory should communicate the association to the recipients of the original report.

4.10.2 Documentation of elimination database associations should be retained or referenced in the case record and maintained in a centralized log.
